Those are the most feared complications for patients and should be specified in the informed consent of third mandibular molars extraction. Detailed information that oral and maxillofacial surgeons provide their patients makes them feel more comfortable with the third molar surgery [32].

➤ Oral / Written Format:

The oral form to provide information is the most used and relevant, but it is also the easier one to forget and it is considered insufficient [29]. In addition, the stress generated while the patient is waiting for the surgery interferes in his ability to retain the information provided in the oral form.

Some authors confirm that verbal communication with the patient is interactive and more efficient than the written format in explaining the information [31]. The best option would be the combination of both formats; explaining everything about the procedure to the patient and providing him with written information so he can read it as long as he needs. This will lead to a better understanding and higher patient satisfaction [34, 35].

➤ Audiovisual format:

Nowadays, information may need alternative formats to written documents or oral consents. The audiovisual format is considered an acceptable method for being very illustrative.

Besides, its application it may be interesting in populations with low education [36]. Many studies confirm that the understanding of information from patients is poor and inadequate [29, 31] so this assessment can be improved by using audio-visual formats [16]. Several authors have reported the benefit of using multimedia technology due to they improve the understanding of informed consent. These are considered to be a direct communication complementary between the doctor and the patient [37, 38].

There is still controversy about the effect of audiovisual informed consent in aspects related to patients. It seems to help in understanding the information as they improve satisfaction of patients with the information provided but there is no sufficient evidence to draw conclusions about the anxiety caused by audiovisual informed consent [39].

3. ORAL SURGERY

The most common surgical procedure carried out in the oral cavity is the third molar extraction. Some indications for this surgery are: caries impossible to be restorable, cyst development due to a fracture, damage to second molar, recurrent infection because the molar has not totally erupted or it is impacted in soft tissues, a need of space for orthodontic treatments and preventive removal, which is considered an extraction of a third molar without symptoms before the development of anticipated problems, among other indications. Furthermore, a very frequent indication is a repetitive episode of pericoronitis associated to pain, bad taste and swelling [40, 41]. According to this kind of operation, the extraction of impacted lower third molar is usually accompanied by pain in the operated area, soft tissue swelling and sometimes restricted mouth opening and in a small percentage, the possibility of suffering from complications such as alveolar osteitis, infections, nerve injuries and abscess or mandible fractures. These consequences are so uncomfortable for daily life of patients, and several factors may influence in their intensity, such as the complexity and duration of surgery [43], the surgeon's technique or patients' mood [42, 44]. Apart from that, there are other factors that also influence in the results of the intervention, for example, it has been reported that the most common range of age is from 18 to 30 years old. Young patients have better circulation, more elasticity and their jaw bone is more resilient than in old patients. Hence, bone removal is more difficult with consequences such as more pain and inflammation and less healing potential of jawbone [46]. Likewise, other characteristics have been studied to establish an association with postoperative recovery such as the position and localization of the third molar in relation with jawbone, distance to alveolar nerve, previous caries with recurrent infection, etc. [47].

The latest advances in surgical techniques, the increase of knowledge about symptoms and possible risks of surgery, and the awareness about postoperative outcomes have permitted to improve surgical techniques using less traumatic methods. This is important because the decrease of symptoms may influence in patients' satisfaction helping them to improve their quality of life and it also minimizes fear of future surgical interventions [45].

Once surgery has been carried out, it has been recognized that postoperative swelling and pain appear as physiological responses of the organism. Postoperative orofacial pain is a direct consequence of the injury caused by the surgery and how the body responds to it. It is important to remember that pain perception varies with each individual and it is based on different factors. The importance of anxiety and the degree of stress that patient suffers before the intervention is crucial in the postoperative pain perception. This has been widely studied by different authors, who defined that anxiety can increase the intensity of postoperative symptoms and also induce greater pain perception by reducing the threshold of pain tolerance.

4. THE MEANING OF ANXIETY

In recent years, anxiety is increasingly associated with several diseases as well as it has been recognized it has some influence on the daily life of patients. Due to the importance that anxiety is taking nowadays, many researchers attempt to find the right definition, although it is not easy due to the fact it is considered a complex concept.

It has been reported an average of 5-7% of population who hardly ever go to dentist due to having fear of dental treatment [48, 50]. In accordance with the International Classification System of Psychiatric Disorders (DSM-IV), when some criteria are present such as avoidance, negative effect on daily life, fear, among others, we can consider that anxiety has reached a clinically significant level [51].

On the one hand, some authors declared that anxiety can be understood as a natural human emotion that resembles other emotional reactions such as joy, anger, fear, sadness, etc. Particularly, anxiety is experienced as an unpleasant emotion that arises in a situation in which the individual perceives a threat with possible negative consequences [49]. On the other hand, other authors proposed that anxiety is a phenomenon that can normally occur in everyone and, under normal conditions, it improves performance and adaptation to social, laboral or academic environment. It has a significant role in mobilizing the individual against threatening or disturbing situations, so it is useful to do what is necessary to avoid the risk, neutralize it or face it [52].

❖ Evolution of anxiety meaning

According to scientific literature, anxiety is considered a relatively modern concept, thus, it would be useful to do a review of its meaning for a better understanding.

During the fifties and later in the sixties, psychological research was focused on schizophrenia recognized as a mental disorder, whereas in the seventies, the interest turned to the evaluation of moods, specifically depression. However, in 1985, two American psychologists called Husain and Jack Maser [53] claimed that the decade of the eighties would be considered in the history as the decade of anxiety, and thereafter it would occupy a special place which still prevails nowadays. Existential philosophy believes that anxiety is a response of human character that is facing the threat of moral values and it appears when the system of values that gives meaning to human life is being threatened. Existentialist psychiatrists give a notable importance to the fact that anxiety is an ontological characteristic of humans. This philosophical current maintains that it is not an attitude among many others, as it could be pleasure or sadness [54].

Nonetheless, from a psychopathological point of view, the concept of anxiety has not always been evenly used. Several Latin words contain the Germanic root "*angh*" but, despite this, the term that has prevailed throughout the Western culture to define that feeling of restlessness has been "anxiety."

This is due to the influence of Freud who defined anxiety as an unpleasant emotional state characterized by apprehension, combination of feelings and disturbing thoughts for the individual [55]. In 1968, Lang [56] set a theory of anxiety defined in three domains, according to which, it is considered a physiological emotional response that includes: behavior, such as displeasure, tension, apprehension, concern; physiological, in which the autonomic nervous system is highly active; and cognitive domains such as the escape in a dangerous situation. Hence, a person could show an intense reaction in subjective category, moderated in the physiological and even mild in the cognitive, whereas another person could experiment just the opposite, concluding that individual reactions are highly variable [57]. The concept of anxiety has evolved into a multitude dimensions considered as a temporary emotional and physiological state, as a personality trait and an explanation of behavior.

Likewise, anxiety not always varies in direct proportion to perceived risk; it can also appear of an irrational manner, which means, in situations without authentic danger [58]. Since the decade of eighties until today, anxiety occupies a relevant place in the field of psychological research. Anxiety is a state of physical and psychological emotion characterized by feelings such as distress, restlessness and insecurity facing to what seems as an imminent threat. From the nineties, it is proposed that anxiety is an emotional response that can be provoked by inner stimuli of the subject as ideas and thoughts or associated to external stimuli like situations in which the subject has to face, to confirm his adaptation to environment. The type of stimulus able to provoke an anxiety response is largely determined by the characteristics of the individual.

In short, anxiety has been seen as a consistent emotional reaction to feelings of tension, apprehension, nervousness and concern accompanying the activation of the sympathetic autonomic nervous system.

❖ Anxiety in surgical procedures

Surgery is perceived as important stress agent. When a surgical intervention is going to be carried out, a feeling of anxiety appears with more or less intensity. Some emotions that usually are felt previously to a surgical procedure are [59]:

- Intense apprehension, fear and anguish to something understood as threatening.
- A state of irritability that can produce loss of concentration.
- A set of somatic symptoms as sweating, palpitations, tightness, fatigue, etc.

Preoperative anxiety is being studied for its consequences attributed to physical and emotional recovery of patients and also because it provides a natural framework for research on coping with stressful events. Several publications confirm that patients with high levels of trait anxiety are associated with greater levels of state anxiety before and after surgery. There is an evolution of anxiety from the moment patient is submitted to the intervention until the recovery has finished. This has significant practical applications in the attempt to reduce anxiety or in developing methods to control this anxiety. Programmed surgeries let clinicians carry out preparatory techniques to reduce preoperative anxiety. When a patient assimilates that he needs to be operated, he realizes his illness, recovery, and possible sequels. Moreover, in the imminent moment before intervention, anxiety is mainly influenced by factors related to the surgery procedure. Overall, from all anxiety-inducing factors, pain stands out from the others. The fact that the individual confronts surgery with high levels of anxiety can have negative influences on his physical and psychological recovery, including more analgesics consumption. For that reason, it would be convenient to evaluate the anxiety before anxiety to indicate the application of psychological techniques for premedication with the objective of minimizing levels of anxiety [60].

Anxiety experienced in a dental office or hospital can be due to various reasons: fear of suffering pain or injury, fear of losing self-control or fear of not being well treated. These fears are usually due to previous personal experiences (specifically in childhood) or opinions from people around. Past traumatic experiences increase significantly pain and anxiety to surgical procedures.

There are studies which support that anxiety decreases tolerance threshold of pain, thereby there is a possibility that non-noxious stimuli can be interpreted by the patient as painful. The first negative effect of dental anxiety and fear would be avoidance of dental treatment. This avoidance will only leads to worsening and deterioration of the case, which will end up by making the patient feels guilty. Moreover, as the time passes, the anxiety level will be increased, the patient's self-esteem will be reduced and quality of life can be compromised and limited [61].

❖ Factors that influence anxiety

The degree of dental anxiety that patients may present is determined by different factors:

- Gender: women generally present higher dental anxiety than men as happens with other anxiety disorders [62, 63]. On the one hand, some studies have found no significant differences in relation to this variable [64], on the other hand, trait and dental anxiety of women seem to be related to the possibility of suffering from a dental phobia accompanied with other psychopathology [65].
- Age: The majority of negative attitudes to dental treatment arise in childhood, as a result of the influence of parents' fears, fear to feel pain and fear to the unknown [65]. Dental anxiety usually decreases with age, which is mainly due to the development of the responsibility to accept the need of treatment and because with age other general or specific phobias are also reduced [62].
- Oral health: when a patient is aware that his oral health status is not appropriate and he needs a treatment, higher levels of dental anxiety are generated [66]. As well as people who have never visit a dentist, their level of dental anxiety is also higher [67].
- Socioeconomic and cultural level: according to some authors a low socioeconomic and educational level is associated with poor oral health, greater difficulty in accessing oral treatments and as a result, higher levels of dental anxiety [69, 70]. Not all studies that investigated this factors influencing dental anxiety have reached the same conclusion [71].
- Factors related the dental treatment: in relation to the procedure itself, the procedures that evoke the highest anxiety levels are surgery and injection of local anesthetic [72]. The quality of treatment that the patient receives is strongly associated with the loss of self-control and vulnerability. Short waiting times are positively valued because if the appointment is delayed, the patient perceives it as a lack of organization and efficiency and it gives him more time to think negatively about the treatment and outcomes. Anxiety experienced by the patient affects not only itself but also affects the professional team. Therefore, oral health professionals must acquire the necessary skills to manage and control the anxiety of their patients [73].

❖ Types of anxiety

There are several classifications to describe different types of anxiety, but the most common is the one that classifies anxiety based on the reason provoking it, whether it's general or specific. Since the seventies, the two types of anxiety recognized from the point of view of psychology of the personality are trait anxiety and state anxiety.

Trait anxiety is defined as an individual tendency to respond anxiously, to interpret many everyday situations as threatening. It is usually accompanied by a neurotic personality. Moreover, state anxiety is perceived by the subject as a transient unpleasant emotion with variable intensity and duration to some situation perceived as threatening [74].

Both anxiety levels are evaluated on a list of 40 items that make up the "*Questionnaire state anxiety trait*" (*State Trait Anxiety Inventory, STAIE-R*) of Spielberger, first described in 1970 and revised in 1983. It is used to assess the level of anxiety and the ability of people to respond to stress [75].

The test consists of two parts with 20 questions each one. The first part, state anxiety, assesses a transitory emotional state characterized by attention, apprehension and subjective feelings consciously perceived. This is caused due to hyperactivity of autonomic nervous system. The other part evaluates trait anxiety with a tendency to anxiety, relatively stable, which characterizes individuals to perceive situations as threatening. Depending on sex and age of subjects who undergo the test, there are reference values that determine if there is trait anxiety, state anxiety or both. If the marks are above the reference values, the patient has anxiety, if the marks are lower, the patient has no anxiety. Several studies have confirmed the reliability and validity of this questionnaire [76].

5. HOW ANXIETY INFLUENCES IN THIRD MOLAR SURGERY

Dental extractions are the most stressful procedures in dentistry and wisdom teeth extraction is considered one of the interventions that generate the highest levels of anxiety [77-80]. One of the basic principles of general and oral surgery is doing the proper diagnosis with a detailed anamnesis thereby anxious patients can be identified directly. Establishing a psychological assessment to identify specifically the patient's level of anxiety, fear to the intervention, and possible depressive symptoms is crucial at this step. An increment of anxiety when patient realizes he is going to be operated is considered normal but the goal is to recognize patients with an excessive level of anxiety and to clarify if it is trait anxiety or fundamentally due to the fact of surgery (state anxiety) [81, 82].

Several studies affirm that when a patient is submitted to a third molar extraction, the anxiety experienced provokes a decrease in the threshold of pain tolerance. This increases the time of intervention, producing higher levels of pain and inflammation [83].

In addition, preoperative anxiety may influence in the development of psychosomatic pathology [as xerostomia and higher blood pressure], which can also adversely affect the postoperative period [24, 69].

Some authors declared that trait anxiety is a good predictor of dental anxiety and patients with high levels of trait anxiety suffer more pain as a sequel to lower third molar extraction [22, 47]. Other authors affirmed that there is a lack in the association between trait anxiety and postoperative pain in this type of intervention [82, 86] and with dental anxiety in general [87]. Some current publications showed that state anxiety and fear to pain are the best predictors of preoperative anxiety before the extraction of impacted lower molars [31]. It has been reported that the state anxiety is more sensitive than trait anxiety before wisdom teeth removal. In postoperative days, the state anxiety decreases while trait anxiety remains stable [88].

Preoperative anxiety is mainly determined by the fear of feeling pain during dental procedure. A bad experience can provoke anxiety and postoperative dental trauma [79].

Fortunately, the pain felt during the intervention is less than the expected but not knowing that generates preoperative anxiety. The level of anxiety during surgery is greater than after it and preoperative anxiety is the one that reaches highest intensity. In fact, some studies show that anxiety decreases in lower third molar extraction when patient has been submitted to similar previous experience [84, 88].

The degree of the satisfaction with the surgery is determined by the preoperative anxiety suffered and whether there are complications or not [89]. For this reason, it is important that oral surgeon to find out if the patient has predisposition to anxiety and in that case, and to apply appropriate preventive and therapeutic methods [47].

On the one hand, conducting a study, aimed to evaluate the effect of informed consent format on anxiety before the extraction of third molars is very interesting due to the importance and prevalence of this surgical intervention. The results of this study are also of importance for the oral health community in order to improve the awareness about the importance of a correct informed consent and how it can influence in the preoperative anxiety. On the other hand, current publications are shrouded in controversy about the association of anxiety before oral surgery and postoperative complications. For that reason, we carried out a second study aimed to analyze the influence of anxiety (both state and trait) in postoperative recovery of the patient submitted to the extraction of mandibular third molar, and also to establish the role of each types of anxiety in the results obtained in an independent and complementary way.

6. A PROSPECTIVE STUDY TO EVALUATE THE EFFECT OF INFORMED CONSENT FORMAT ON PREOPERATIVE ANXIETY IN PATIENTS UNDERGOING INFERIOR THIRD MOLAR SURGERY

Once the objectives of the study have been developed, the proposed hypothesis was: One informed consent format is more effective than the others reducing preoperative anxiety of the patient to be subjected of third molar extraction.

We present an experimental, longitudinal, prospective study that was carried out in the Department of Stomatology of the University of Seville, within the Master of Oral Surgery at the University of Seville, and in the Service of Oral and Maxillofacial Surgery of the University Hospital Virgen del Rocío, Seville, Spain. In this research, a total of 91 patients, (35 male and 56 female) aged between 14 and 64 years were voluntary submitted to third molar extraction with the following inclusion criteria:

- ✓ Patients who required extraction of lower third molars under local anesthesia.
- ✓ Patients who agreed to enter the study and did not meet any of the exclusion criteria.
- ✓ Only patients with ASA I and II types were accepted.

These exclusion criteria were:

- ✓ Patients under 12 and over 70.
- ✓ Patients suffering pain due to the third molar at operating day.
- ✓ Patients with a physical or mental impairment that affect cognitive or communication skills.
- ✓ Patients undergoing treatment with anxiolytics.
- ✓ Patients who had previously undergone other oral surgery procedures.
- ✓ Patients who did not correctly complete the questionnaires.
- ✓ Patients who were suffering Trait Anxiety.

Before surgery, patients were asked to complete the test Spielberger State-Trait Anxiety Inventory, also known as STAI test. With it, in order to assess whether the patient had trait anxiety and / or state anxiety at that moment. This test consists of a 40 items questionnaire designed to evaluate two independent concepts of anxiety: anxiety as state (transient emotional condition) and trait anxiety [propensity anxious relatively stable]. Each question has a 4 options response system depending on the intensity (0 = almost never / no, 1 = something / sometimes 2 = very / often, 3 = much / almost always). The total score varies between 0 and 60 points with a direct/positive answer with another reverse/negative one. The total score is the sum of each positive and negative answer of each type of anxiety responses. There were some reference values to determine the type of anxiety (trait anxiety, state anxiety or both) depending on patient's sex and age.

After the completion of the consent, the clinician provided the patient with detailed information about the surgery. Patients were randomly divided into three groups according to the consent format they have been given. Thus, the first group (30 patients) was provided with the information verbally, the second group (31 patients) was provided with the information by written form and. The third group (30 patients) was provided with the information using a video (audiovisual format).

The information provided was the same in all three formats:

- ✓ Oral Format: the surgeon verbally explained to the patient the information written in the consent format.
- ✓ Written Format: the patient read the information.
- ✓ Audiovisual Format: the patient watched a video that contains images and verbal explanations of the intervention.

After receiving the information, patients filled out another test to record their state of anxiety at that moment before surgery. This assessment was performed by two simple items that allowed us to evaluate the situation of the patient after informed consent process.

The first question, "At this moment, do you feel nervous?" helped us to confirm the patient's condition at that moment. The second question was "The information provided before the intervention, helped you to be calm or made you feel more nervous?" This question was referenced to the information received. Once the second questionnaire has been collected, each patient signed the informed consent document and the surgery was carried out.

The STAI test determined that 70% of the patients did not have state anxiety before the surgery. Analyzing the informed consent format associated with state anxiety, the results showed that the third group recorded the highest level of anxiety (audiovisual format: $1.50 \pm$

0.82) compared with the first group (verbal format) (1.23 ± 0.89) and the second group recorded the lowest levels of anxiety (1.12 ± 0.80).

The average of state anxiety in each group of the study was similar and the p-value (0.535) did not reveal significant differences so the results in the three groups were not statistically significant. Nonetheless, it is important to state that the oral and written information provided to the patients (0.97 ± 1.21 and 0.29 ± 0.97 , respectively) had different effects on anxiety levels compared to the video recording, which increased patients' anxiety (0.57 ± 1.43) with statistically significant differences. The difference between values corresponding to the written and the oral information was not statistically significant.

Regarding to the relationship between sex and state anxiety, we observed that men have an average of state anxiety of 13.26 ± 7.13 and women of 18.75 ± 11.07 . Data revealed that statistically significant differences were obtained, so the value of state anxiety for men and women in our sample has differences to consider (Figure 1).

7. INFLUENCE OF STATE ANXIETY AND TRAIT ANXIETY ON POSTOPERATIVE RECOVERY IN ORAL SURGERY

It has been widely studied how anxiety can influence postoperative outcomes of oral surgery, specifically pain experience. Several researchers concluded that facing a surgical procedure with high levels of stress and anxiety may be worsening both physical and psychological recovery [90]. This means a higher consumption of analgesics and a longer hospitalization, which may also affect the budget of the health care system [91, 92].

As explained earlier, anxiety can be classified as trait anxiety or as state anxiety.

The current study revealed that both trait anxiety and state anxiety are independent, which means that having one of these types of anxiety does not imply nor prevent having the other [22]. Nonetheless, scientific community is shrouded in controversy about this topic because the results were obtained with different scales what makes it difficult to compare their results [93].

S/A: state anxiety average of the sample.

Figure 1. State anxiety value in men and women of the sample.

A prospective study was carried out to analyze the influence of state and trait anxiety in postoperative recovery after third molar extraction, with the aim of establishing the role of each types of anxiety in an independent and complementary way.

A total of 88 patient underwent lower third molar extraction for the first time, 31 (35,2%) men and 57 (64,8%) women. The age average was 30,4 years $\pm$ 10,1.

The exclusion criteria were:

- ✓ To not complete all the requirements criteria of the study.
- ✓ To have been submitted to a previous third molar surgery.
- ✓ Not participating voluntarily
- ✓ Cognitive and communication impaired abilities.
- ✓ Under anxiolytic treatment or suffering anxiety attacks.
- ✓ Surgery duration of more than 30 minutes.
- ✓ Patients with medical conditions.
- ✓ Patients with acute pericoronitis or severe periodontal disease at the time of surgery.

To evaluate the anxiety, an hour before the surgery, patients were asked to fill out the Spielberger State-Trait Anxiety Inventory - Trait (STAI-T). This questionnaire is composed of 20 items with a 4 levels frequency scale ranging from "almost never" to "almost always" to record the degree of anxiety in some situations that patients perceived as threatening. After this, subjects were informed about the surgery and postoperative recovery. Thirty minutes before the surgery has been carried out, patients were asked to complete the Spielberger State-Trait Anxiety Inventory - State (STAI-S). This is a 20 items questionnaire using a 4 levels frequency scale, but in this case, the range was from 0 to 3.

The results obtained from both STAI-T and STAI-S, were between 0 and 60, considering valid from 20 for young men (percentile 50 in validation) and from 22 for young women (percentile 50 in validation studies).

Regarding the surgical procedure, all the molar extractions were performed by eight postgraduate students at the University of Seville (Spain) with the same experience level. In all cases, nerve-block local anesthesia was performed for the inferior dental nerve, lingual nerve, and buccal nerve. After raising a mucoperiosteal flap and removing the bone, coronal section, or root section was performed when it was necessary. Adequate instructions and recommendations about postoperative recovery period were explained to every patient and antibiotic (amoxicillin 500 mg/8 h for 7 days) and an anti-inflammatory (ibuprofen 600 mg for 7 days) were prescribed. The data showed that 30 (37,5%) of 88 patients included in the study presented trait anxiety and 41 patients (45,4%) presented state anxiety. Statistically significant results showed that the consumption of analgesics was higher in positive trait anxiety group, while differences between both groups regarding pain were detected only on specific moments (at the end of the study procedure) and regarding swelling at the beginning. Only the influence of state anxiety has been previously studied in publications, so the clinical results of this research are useful in two ways.

On the one hand, the influence of the state and trait anxiety in the postoperative period has been objectively demonstrated. On the other hand, our study also supports the administration of tranquilizers before surgery, although this should be evaluated together with the costs and possible risks of medication. Therefore, some activities that decrease anxiety must be promoted.

CONCLUSION AND FUTURE LINE OF RESEARCH

- In the sample studied, the state anxiety is more common in women.
- The information provided to patients about the surgical procedure of the third molar before the intervention slightly decreases preoperative anxiety.
- There are significant differences in the preoperative anxiety level depending on the format in which the information is explained. The audiovisual format increases significantly the anxiety compared to the written and verbal format which decrease the level of anxiety.

The anxiety that a patient suffers from extracting third molars is mainly determined by his personality and previous experiences in the field of dentistry and oral surgery. The patient that is going to be submitted to the surgical removal of lower third molar must be properly informed about the procedure, predictable and possible postoperative complications, risks of surgery, etc. Informing patients can influence their anxiety but this is mandatory before asking them to sign the informed consent. It would be interesting to develop new studies about the best moment to provide the patient with the information, and if there are differences between informing the patient immediately before surgery or on the day of the diagnosis. It would be also carrying out a study with the objective of measuring the influence of different factures on patient's anxiety level. Therefore, clinicians should be able to determine whether the patient is anxious, the necessary amount of information to be explained, and the best moment and format to deliver this information.

Chapter 391

ZINC DEFICIENCY AFTER BARIATRIC SURGERY: ETIOLOGY, HEALTH IMPLICATIONS AND MANAGEMENT

Jaime Ruiz-Tovar^{1,*}, MD, PhD and Carolina Llaveró²

¹Department of Surgery, University Hospital Rey Juan Carlos, Madrid, Spain

²Department of Surgical Nursery, Sureste Hospital, Madrid, Spain

ABSTRACT

Bariatric surgery leads to a significant body weight reduction, and improvement of obesity-related comorbidities. However, it is associated with a higher risk of presenting some nutritional deficiencies. These deficiencies are especially relevant after mixed or malabsorptive procedures.

Deficiencies in micronutrients after bariatric procedures are a known threat if not corrected appropriately.

Though zinc deficiency is not considered among the most frequent deficiencies after bariatric surgery, several studies have shown that its frequency might overcome 10%, even after restrictive procedures and in patients with multivitamin supplements intake.

Zinc is the second most prevalent trace found in the human body after iron. It is essential for normal cell function and metabolism, playing a central role in over 300 enzymatic reactions, and protects cells from free radical damage. The central role of zinc in cell growth and differentiation explains the dramatic effect of zinc deficiency in tissues with a rapid cell turnover such as hair growth.

In recent years much interest has been generated by the possibility that subclinical zinc deficiency may significantly increase the incidence of and morbidity and mortality from diarrhea and upper respiratory tract infections. Clinical manifestations of zinc deficiency include delayed sexual maturation, impotence, hypogonadism, oligospermia, alopecia, dysgeusia, immune dysfunction, night blindness, impaired wound healing, and various skin lesions.

After bariatric surgery, zinc deficiency is often associated with other micronutrients deficiencies, mainly iron. It has been demonstrated that zinc and iron levels, both within

* Corresponding Author's Email: jruiztovar@gmail.com.

the normal range, but close to the minimum level of the range, can be associated with hair loss, mainly between the 6th and 9th postoperative month.

For the evaluation of zinc status, plasma levels are generally a good index of zinc status in healthy individuals.

Zinc supplements are usually indicated for patients with low zinc levels, depending upon the clinical context. In obese patients after bariatric surgery, zinc supplementation can be considered even in patients with serum levels within the normal range, when iron levels are also close to the minimum value of normality and the patient complain of alopecia.

INTRODUCTION

Zinc is the second most prevalent trace found in the human body after iron. Along with iron, iodine, and vitamin A, zinc deficiency is one of the most important micronutrient deficiencies globally. Serum zinc deficiency can determine the appearance of several diseases. Most of these deficiencies are caused by inadequate nutrition. Meats, nuts and lentils are excellent sources of zinc. However, it has been estimated that nearly 45% of adults may have inadequate zinc intakes. Mild zinc deficiency appears to be common, especially in developing countries. Individuals in developing countries are at risk of zinc deficiency because the diet is relatively low in zinc and contain significant amounts of phytates (which reduce zinc absorption) [1, 2]. The Food and Nutrition Board of the Institute of Medicine and the World Health Organization (WHO) have published standard recommendations for daily zinc intake. Requirements vary by age and gender, rising from 3 mg daily in early childhood to 8 mg daily for adult women, and 11 mg daily for adult men. Requirements are slightly higher during pregnancy and lactation [3].

ZINC METABOLISM

Around 60% of total body zinc is in bone and muscle pools with slow turnover. Zinc is absorbed mainly in the duodenum and jejunum, and to a lesser extent in the ileum and colon. Typically, zinc absorption is 20 to 40% efficient, and may be related to zinc status [4].

During digestion, dietary zinc is released and forms complexes with different ligands, namely amino acids, phosphates, organic acids, and histidines. Zinc-ligand complexes are then absorbed through the intestinal mucosa. Pancreatic enzymes are necessary for release of dietary zinc, and pancreatic juices may contain zinc-complexing ligands. Once absorbed, the portal circulation carries zinc to the liver. There is an intricate homeostatic control of zinc absorption, regulated by metallothionein, a metalloprotein that binds copper and other divalent cations [5].

The major route of zinc excretion is via the gastrointestinal tract. Up to 10% of the circulating zinc is also excreted through urine. Zinc homeostasis is probably maintained by a combination of changes in fractional absorption and endogenous fecal zinc excretion [1].

BIOLOGICAL ROLE OF ZINC

The biological role of zinc mainly depends on the ability to form tight bonds with certain amino acids, especially histidine and cysteine. When zinc binds four amino acids (tetradentate configuration), it serves a structural role maintaining protein structure (such as the beta-pleated sheet), and maintains nuclear stability and histone structure. When zinc binds three amino acids, the fourth site is temporarily taken by a water molecule; in this form, zinc can play a role in the metabolic activity of many proteins. Approximately 250 proteins contain zinc. These include enzymes such as angiotensin converting enzyme, alkaline phosphatase, carbonic anhydrase, DNA and RNA polymerases, copper-zinc superoxide dismutase, and metallothionein, as well as a large family of zinc proteins involved in gene transcription (such as the zinc finger proteins). Zinc has important roles both in cell division as well as apoptosis (programmed cell death) [1]. Zinc plays a central role in over 300 enzymatic reactions, and protects cells from free radical damage [6, 7].

ZINC DEFICIENCY

Mild dietary zinc deficiency impairs growth velocity while severe depletion of zinc leads to growth retardation. Other clinical manifestations of zinc deficiency include delayed sexual maturation, impotence, hypogonadism, oligospermia, alopecia, dysgeusia, immune dysfunction, nictalopia, impaired wound healing, and various skin lesions. Other signs and symptoms of zinc deficiency include loss of taste, change in hair color, impaired appetite and decreased sperm counts [8].

Findings such as these, suggesting zinc deficiency, have been described in chronic diseases such as malnutrition, malabsorption syndromes (such as chronic inflammatory bowel disease), prolonged breast feeding, cirrhotic patients and elderly individuals with poor diet quality. In the latter cases, the dietary zinc deficiency may have been exacerbated by medications that increase urinary losses of zinc, including thiazides, loop diuretics, and angiotensin receptor blockers [9].

In recent years much interest has been generated by the possibility that subclinical zinc deficiency may significantly increase the incidence of and morbidity and mortality from diarrhea and upper respiratory tract infections [8].

ZINC DEFICIENCY AFTER BARIATRIC SURGERY

In the recent decades, reduced zinc absorption and stores have been demonstrated in patients who have undergone bariatric surgery, mainly malabsorptive procedures [6]. Though zinc deficiency is not considered among the most frequent deficiencies after bariatric surgery, several studies have shown that its frequency might overcome 10%, even after restrictive procedures and in patients with multivitamin supplements intake. In malabsorptive procedures, as it has been previously explained, zinc is absorbed in duodenum and jejunum, which are the main parts of small bowel that are bypassed in malabsorptive techniques. Similar to zinc, other minerals are also absorbed in these locations of the small bowel (iron,

calcium,...). Therefore, deficiencies in micronutrients after bariatric procedures are a known threat if not corrected appropriately [9-11]. Another factor that might contribute to an impairment of zinc levels, is a reduced stomach production of hydrochloric acid required for zinc bioavailability and absorption [12, 13]. The reduction of gastric acid segregation is probably the main explanation for zinc deficiencies after restrictive procedures, such as sleeve gastrectomy, as there is no malabsorption associated with this procedure. Absorption is also related to zinc concentration in food and red meat is the richest common source of readily available zinc, providing about 50% of dietary intake [14]. Some studies which evaluated food records found that zinc intake was not enough in almost all patients in the first months after bariatric surgery, based on a limited quantity of red meat intake. In patients undergoing any type of bariatric surgery, solid food intake begins 1 month after surgery, but chicken is the main meat included in this first solid diet. Red meat is progressively introduced, but most patients complained of difficult digestions with this red meat and they decide to reduce the ingestion. It is around the 3rd postoperative month, when they can ingest red meat without problems.

EVALUATION OF ZINC STATUS

Serum levels of zinc are often the only method performed to evaluate zinc status. After bariatric surgery, serum levels of zinc are included in the routinary blood analysis performed for monitoring the nutritional status in the postoperative course. However, it has been demonstrated that serum levels do not necessarily correlate with tissue levels and do not reliably identify individuals with zinc deficiency. Although plasma levels can be a good index of zinc status in healthy individuals, these levels are depressed during inflammatory disease states. It is important to remember that obesity is considered as a pro-inflammatory entity, and the rapid weight loss after surgery is identified by the organism as an aggression, associating an inflammatory response, that ends once a weight stability is achieved [15]. Thus, the accuracy of serum zinc levels for the diagnosis of zinc deficiency is low.

Erythrocyte concentrations of zinc may provide a more useful measure of zinc status during acute or chronic inflammation. Serum superoxide dismutase and erythrocyte alkaline phosphatase activities are functional indices that can also be used to indirectly assess zinc status [16]. The main limit of these tests is that they are not widely available.

ALOPECIA AND MILD ZINC DEFICIENCY AFTER BARIATRIC SURGERY

The central role of zinc in cell growth and differentiation explains the dramatic effect of zinc deficiency in tissues with a rapid cell turnover, such as the hair growth [12]. The phenomenon of postoperative hair loss is multifactorial. Though hair loss is mainly due to a rapid weight loss, micronutrient deficiencies must be discarded. Zinc is the most frequently suspected deficiency with rapid clinical responses reported from therapy [6]. A recent study of our group showed that zinc levels within the normal range, but close to the minimum value, can be associated with hair loss in females between the 3rd and the 9th postoperative months, especially when iron levels are also close to the minimum limit. We proposed to

study a new variable, called Addition (serum zinc + serum iron). When Addition levels are below 115, these values are associated with alopecia, that disappeared with zinc supplementation [17]. These findings support the fact that serum levels of zinc within the normal range in the postoperative course of bariatric surgery, are not a good marker for zinc status.

MANAGEMENT OF ZINC DEFICIENCY

The fact that after zinc supplement intake hair loss stopped in most patients of our study, even in those with zinc levels within normal range, reveals that there is a mild zinc deficiency after sleeve gastrectomy, that probably alone is not enough to produce hair loss, but associated with iron mild deficiency (also with levels within normal range) it can appear. There are currently no guidelines for zinc supplementation and optimal dose and rules of prescription after bariatric surgery are still to be determined. In our series, just a small dose of 12.5mg/day (125% RDA) during 2 months was enough to slightly increase the serum zinc levels and to stop hair loss. As prophylactic measure against hair loss after bariatric surgery, it could be hypothesized a routinely supplementation with low doses of zinc [17].

During zinc supplementation, it is recommended to monitor periodically the serum concentrations in order to avoid the appearance of adverse effects associated with overload. Anyway, humans are very tolerant of high zinc intakes up to 100 mg/day (1000% RDA). Mega-dose supplementation or high zinc intake from contaminated food has been associated with nonspecific gastrointestinal symptoms, including abdominal pain, diarrhea, nausea, and vomiting. Zinc overload may interfere with copper absorption, and high zinc intakes (> 150 mg/day) can lead to copper deficiency. Treatment for zinc toxicity is primarily supportive, although chelation with calcium disodium ethylenediaminetetraacetate (CaNa₂EDTA) has been used in some cases of severe toxicity [18].

ABSTRACT

The rising prevalence of obesity (body mass index of ≥ 30 kg/m²) in more than 100 countries has been described as a global pandemic. Studies have found that surgery results in more significant and sustained weight loss, when compared to dietary and lifestyle interventions, in individuals with medically-complicated obesity.

Zinc is an essential component of the catalytic site of hundreds of different metalloenzymes where it functions as a Lewis acid.

The small intestine is the main site of zinc absorption via transporter expression which is regulated in part by dietary zinc intake. Zinc deficiency is a clinical concern since it may result in multiple clinical symptoms.

After bariatric surgery, the prevalence of biochemical zinc deficiency has been reported to range from 5% to 83%. It has been suggested that bariatric procedures that result in restriction may have lower rates of zinc deficiency compared to bariatric procedures that produce restriction as well as malabsorption.

The mechanisms for zinc deficiency after bariatric surgery have not been fully delineated but may include decreased intake, poor food tolerability, decreased surface

area for absorption, rapid oral-cecal transit, altered compensatory mechanisms, and/or small intestinal bacterial overgrowth.

Elevated serum folic acid levels, a marker for small intestinal bacterial overgrowth, is common after gastric bypass surgery, and small bowel bacterial overgrowth is associated with decreased zinc absorption. We evaluated 230 patients after gastric bypass surgery and 145 patients had elevated serum folate levels, supporting 63% prevalence for small intestinal bacterial overgrowth. In 54 patients with normal serum folate levels, 43 had normal zinc levels, while among 118 patients with elevated serum folate, 78 had low serum zinc (Chi-squared 2X2: $P < 0.001$), supporting upper gut bacterial overgrowth as a mechanism for biochemical zinc deficiency.

We have evaluated 43 patients who underwent upper endoscopy after gastric bypass surgery. In 17 out of 43 (40%) of these patients, there was an abnormal finding at upper endoscopy: gastrojejunal anastomotic stricture (obstruction) or gastrojejunal anastomotic ulcer. In 8 patients with gastrojejunal ulceration, 66% of the patients had low serum zinc levels. In patients who had elevated serum folate levels, there was no increased risk of gastrojejunal ulceration (Chi-squared 2X2: $P = 0.53$).

Currently, recommendations regarding routine screening for zinc deficiency or the use of daily oral zinc supplementation in individuals after bariatric surgery are not based on clinical trials. Gaps that exist in our understanding of this clinical disorder are summarized in this chapter. Since present physiological evidence supports zinc absorption primarily in the jejunum by a transcellular route involving a zinc-specific transporter, Zip4, proposed studies should examine potential post-operative changes in zinc transport and the potential for reversibility with antibiotic treatment of small intestinal bacterial overgrowth.

INTRODUCTION

The Pandemic of Obesity

As shown in Table 1, obesity is consistent with a Body Mass Index (BMI) $\geq 30 \text{ kg/m}^2$ while overweight people have a BMI $\geq 25 \text{ kg/m}^2$ [1]. Over the past decades, the rising prevalence of overweight and obesity in more than 100 countries has been described as a global pandemic [2-4].

Table 1. Obesity can be defined by body mass index or BMI

BMI (kg/m ²)	Definition	Obesity Class
18.5-24.9	Normal	
25-29.9	Overweight	
30-34.9	Obesity	I
35-39.9	Obesity	II
40.0-	Obesity	III

There is a universal concern about health risks associated with increased obesity.

According to a recent study, the conditions overweight and obesity were estimated to cause 3.4 million deaths, 4% of life years lost and 4% of disability adjusted life years across the globe in 2010 [5]. Worldwide, the combined prevalence of overweight and obesity rose by 27.5% for adults and 47.1% for children between 1980 and 2013 (see Figure 1). The

worldwide number of overweight and obese adults increased from 857 million in 1980 to 2.1 billion in 2013.

Figure 1. There was a rise in the worldwide prevalence (in percentages) of men and women who were overweight or obesity in 1980 and in 2013.

Figure 2. There was a rise in percentages of adults aged 18 years and older who were obese in the United States in 2011, 2012, and 2013.

Data from studies in the United States have suggested that during the past 20 years, there has been a dramatic increase in obesity and therefore rates remain high (see Figure 2). More than one-third of U.S. adults (34.9%) and approximately 17% (or 12.7 million) of children and adolescents aged 2 to 19 years-old are obese [6, 7].

The connection between the rising rates of obesity and rising medical spending is also clear. In 1998 the medical costs of obesity were estimated to be as high as \$78.5 billion and these costs increased to \$147 billion by 2008 (see Figure 3). In 2006, obese individuals had medical spending that was \$1,429 greater than spending for normal-weight individuals [8].

Figure 3. There were increased estimates of the medical costs (in billions of dollars) related to obesity in the United States in 1998 and in 2008.

Surgical Management of Obesity

Morbid obesity has been directly associated with an extensive list of significant co-morbid conditions, including the metabolic syndrome, cardiovascular diseases, obstructive sleep apnea, certain carcinomas (i.e., endometrial, breast, colon), osteoarthritis and non-alcoholic steatohepatitis. Childhood obesity is associated with a higher chance of obesity and disability when reaching adulthood.

In addition to increased future risks, obese children experience breathing difficulties, increased risk of fractures, hypertension, insulin resistance, and psychological disorders.

Management options for obesity include dietary and activity program, pharmacological therapy, endoscopic interventions, and surgical procedures. The initial management of obesity includes dietary and lifestyle interventions. Recent studies have showed that more focus on healthy eating and physical activity have led to a potential decline in obesity rates in school children in a school based program [9].

However dietary and activity program, and pharmacological therapy, have resulted in poor weight loss and/or poor maintenance of weight loss especially in individuals with severe obesity [10, 11]. Controlled studies and cohort studies have found that bariatric surgery results in more dramatic and sustained weight loss as compared to nonsurgical interventions [12-14].

Bariatric surgical procedures (see Figure 4) are considered for individuals with a body mass index $> 39.9 \text{ kg/m}^2$ or a body mass index of $> 34.9 \text{ kg/m}^2$ with an associated significant co-morbidity, e.g., diabetes mellitus, obstructive sleep apnea, Pickwickian syndrome, obesity-related cardiomyopathy, or disabling osteoarthritis. Currently, only about 1% of the morbidly obese population is being evaluated for this surgical strategy. Clinical outcome studies have shown significant reductions in long term mortality after gastric bypass surgery, including mortality caused by cardiovascular events, diabetes, and cancer [15-18]. These data support the current indications of bariatric surgery for the treatment of medically-complicated obesity.

Figure 4. Representations of major bariatric surgical procedures. Restrictive bariatric surgical procedures include the adjustable gastric band and the vertical sleeve gastrectomy. Bariatric surgical procedures that result in both restriction as well as in some malabsorption include the Roux-en-Y gastric bypass, the biliopancreatic diversion, and the duodenal switch. In gastric bypass surgery and in biliopancreatic diversion, the length of the biliopancreatic limb (e.g., bypassed small intestine) is related to the distance from the pylorus to the jejuno-jejunal anastomosis. In gastric bypass surgery and in biliopancreatic diversion, small intestine distal to the jejuno-jejunal anastomosis (e.g., the common channel) is required to allow mixing of micronutrients with bile and pancreatic secretions. (Reproduced with permission from Bal, BS; et al. *Nature Rev Endocrinol* 2012; 8: 544-556.).

Data from a global survey shows that the total number of bariatric procedures performed worldwide in 2013 was 468,609, in which 95.7% were completed laparoscopically. The highest number ($n = 154,276$) were performed in the USA/Canada region. The most commonly performed procedure in the world was Roux-en-Y gastric bypass (RYGB), at 45%, followed by the vertical sleeve gastrectomy (SG), at 37%, and then the adjustable gastric banding (AGB), at 10%. The most significant changes were the worldwide rise in utilization of SG from 0% in 2003 to 37% of bariatric surgical procedures in 2013, with a related decline in the performance of AGB after its peak in 2008 [19]. The number of procedures performed in the USA/Canada has increased over time, with the number being 179000 in 2013 [23], which results in approximately 40% of the global total.

Bariatric surgeries involving the stomach are restrictive in general, while surgery involving the small intestine can also result in malabsorption. Vertical sleeve gastrectomy and adjustable gastric band are the commonly performed restrictive procedures, while Roux-en-Y gastric bypass and biliopancreatic diversion (more rarely performed due to the risks of malnutrition) result in malabsorption in addition to restriction. Procedures designed to include a malabsorptive component produce greater nutritional deficiencies than restrictive surgeries.

In Roux-en-Y gastric bypass, a small gastric pouch is created by complete division of the stomach, and then the proximal gastric pouch is directly connected to jejunum that was divided commonly 40 to 50 cm distal to the ligament of Treitz. The location of the jejuno-jejunal anastomosis is important because a long proximal alimentary limb (which is distal to the proximal gastric pouch) results in a short common channel (e.g., the small intestine distal to the jejuno-jejunostomy). Patients with a short common channel are more at risk for developing malabsorption and malnutrition, compared to patients with longer common channels, due to decreased surface area of small intestine available for the absorption of micronutrients and possible alteration of bacterial flora [24].

The vertical sleeve gastrectomy is gaining popularity worldwide and is now commonly performed in the USA. The gastric fundus and body are surgically excised, leaving a narrow, tubular stomach along the lesser curvature of the stomach. It allows for an immediate restriction of caloric intake without an intestinal anastomosis, placement of an extrinsic foreign body, or the need for adjustments [24].

The adjustable gastric band is primarily a restrictive strategy that does not bypass any part of the gastrointestinal tract. A plastic latch is used to hold a soft, silicone ring circumferentially around the upper stomach just distal to the gastroesophageal junction, leaving a very small pouch available for food. A subcutaneous access port is connected via tubing to the silicone ring or band. Sterile fluid added to the port induces extrinsic compression of the proximal gastric lumen by inflating the balloon positioned around the proximal stomach [24]. Biliopancreatic diversion involves a distal gastrectomy with closure of the duodenal stump. The jejunum is divided and the distal limb is anastomosed to the proximal stomach, while the proximal limb (termed the biliopancreatic limb) is anastomosed to the ileum. A variation of this procedure, termed biliopancreatic diversion with duodenal switch, was developed to decrease the adverse effects of dumping syndrome. In this procedure restrictive component is maintained by a partial gastrectomy of 70% to 80% of the greater curvature of the stomach in a gastric sleeve configuration [25].

Vertical-banded gastroplasty is another bariatric procedure that was developed to be restrictive in nature and was designed to decrease morbidity. Due to an unacceptably high failure to maintain long term weight loss, this procedure is now rarely performed [26].

PHYSIOLOGY OF ZINC

Zinc is the second most abundant trace element in the body after iron. The average adult stores a total of 2 to 3 grams of zinc, mainly present in muscle and bone. In clinical research studies of zinc metabolism, an exchangeable zinc pool mathematically estimates compartments in the body in which zinc can rapidly exchange with serum zinc. The exchangeable zinc pool in adults has been correlated with dietary zinc intake. Therefore, this concept may provide a useful measure in studies of zinc metabolism. Zinc is required as a cofactor for more than 100 metalloenzymes where it functions as a Lewis acid. These enzymes are involved in synthesis of DNA and RNA, release of vitamin A from liver, metabolism of carbohydrates, disposal of free radicals, biosynthesis of heme and essential fatty acids, and transport of carbon dioxide. In addition, zinc appears to stabilize cell membranes, assists in immune function, and is involved in the synthesis, storage and release of insulin from the pancreas. Zinc is physiologically important for normal taste perception, wound healing, production of sperm, and fetal development.

Zinc is principally absorbed in the small intestine. The rate of the zinc absorption varies from 15-40% depending on the zinc status in the body: if more zinc is needed, more is absorbed. Dietary factors also influence its absorption, and zinc is better absorbed when the stomach is empty. Meat, shellfish, and nuts are good sources of bioavailable zinc, whereas zinc in grains and legumes is less bioavailable. Absorption of dietary zinc may be inhibited by dietary phytate, fiber, oxalate, iron, and copper.

Zinc is absorbed into intestinal mucosal cells by passive carrier-mediated diffusion. A portion of absorbed zinc is utilized in the metabolic functions of the cell itself. Alternatively, zinc may be retained within mucosal cells by interaction with metallothionein, a binding protein. By this mechanism, metallothionein in intestinal cells may be involved in the regulation of zinc absorption. This step is mediated by an energy dependent process, is regulated by body stores of zinc, and is potentially altered by the presence of iron cations [28, 29].

The level of zinc supplementation does not have a significant differential effect on the magnitude of its absorption. Recent advances have shown that zinc absorption is a complex process involving the participation of several transporters from both the ZIP (solute linked carrier SLC39) and the ZnT (solute-linked carrier SLC30) families. ZIP4 is considered the primary regulator of zinc uptake in the intestinal cells, and ZnT1 is pivotal for the zinc efflux from the enterocyte into the blood [30-33]. The expression of these zinc transporters is regulated by cytokines, hormones, and zinc levels in the body [30]. It is believed that surgery on the small intestine can cause changes in the expression of zinc transporters, resulting in important effects on zinc homeostasis [31].

Zinc's main transport vehicle in the blood is albumin. Some zinc also binds to transferrin. In conditions of iron overload, transferrin is saturated hence leaving too few sites available for zinc binding. The converse is also true: large doses of zinc inhibit iron absorption. A proportion of the circulating zinc is taken up by the pancreas, where it is incorporated into digestive enzymes that are released at mealtime. This recycling of zinc in the body from small intestine to the pancreas and back to the small intestine is known as enteropancreatic circulation. As zinc circulates through the small intestine, it may not be absorbed by intestinal mucosal cells. Zinc is also excreted in intestinal cells shed into the intestinal lumen. The

primary excretion of zinc from the body is within feces. The body also loses small amounts of zinc in urine, hair, skin cells that are sloughed, sweat, menstrual fluid, and semen.

PREOPERATIVE AND POSTOPERATIVE ZINC METABOLISM

Zinc and Obesity

An estimated 17.3% of the world's population is at risk of inadequate zinc intake [34]. Preoperative determination of zinc levels in obese individuals considering bariatric surgery suggests that biochemical zinc deficiency (e.g., low serum levels of zinc) is common in this population. Multiple studies evaluating morbidly obese individuals preoperatively have found that the prevalence of zinc deficiency ranges from 15% to 73.9% [35-39]. Such wide differences in results may be attributable to poor dietary habits in the studied population, socioeconomic factors, gastrointestinal pathologies, and/or the use of different cutoff points for defining biochemical zinc deficiency.

Sanchez et al evaluated 103 morbidly obese women for micronutrient deficiencies before proceeding to gastric bypass surgery. The mean BMI of these individuals was 43.1 ± 5.3 kg/m² and the mean age was 36.0 ± 9.6 years-old in the study group. Low hair zinc concentrations were detected in about 15% of the patients [35]. In a second study by Gobato et al, biochemical zinc deficiency was found in 20 (55.5%) of 36 morbidly obese patients presenting for preoperative evaluation for gastric bypass surgery [36].

Although the exact mechanism to explain zinc deficiency in the obese patient population is not clear, several mechanisms have been hypothesized. Dietary intake may be both an origin for obesity as well as an origin for the development of micronutrient deficiencies. The obese patient usually has a high intake of calorie dense food rich in large amounts of carbohydrate and fat, but poor in vitamins and minerals [40-44]. A substantial proportion of these patients also have problematic eating behaviors such as loss of control eating, night eating syndrome, binge eating disorder, and bulimia nervosa [45]. Additionally, these individuals have altered bioavailability of micronutrients, due to "high calorie malnutrition", which is a state of excess intake of calories with concurrent nutrient deficiencies resulting in inadequate ability to utilize these calories efficiently; the toxic by-products of incomplete biochemical reactions create a vicious cycle resulting in further weight gain, eating disorders, metabolic syndrome, and fatigue [41]. Another potential explanation for biochemical zinc deficiency could be dilution effects of extracellular concentrations due to elevated quantities of total body water in individuals with obesity, since the extracellular compartment is relatively larger than the intracellular compartment, causing imbalances in the vitamin status [46]. It has also been postulated that there is decreased levels of bioavailable zinc in the obese patients due to sequestration of a majority of zinc in increased body fat [47, 48]. Small intestinal bacterial overgrowth (SIBO), especially in diabetic patients with concurrent malabsorption is another potential explanation for the development of zinc deficiency.

Zinc and Bariatric Surgery

Although bariatric surgical procedures have shown promising results in sustained extensive weight loss, chronic complications including macronutrient and micronutrient deficiencies occur. Micronutrient disorders including biochemical zinc deficiency are commonly found in individuals before bariatric surgery and have been shown to persist or worsen after bariatric surgery.

Clinical zinc deficiency is a major clinical concern in bariatric surgery patients because of the important function of this mineral and the co-morbidities related to its deficiency, such as growth retardation, hypogonadism, dermatitis, alopecia, poor immunity, acrodermatitis, poor healing, and impaired neuropsychological performance [49-51]. The potential role of zinc in development of diarrhea is not as clear since many individuals with diarrhea can develop biochemical zinc deficiency. Many bariatric surgery patients are women in child bearing age, and zinc deficiency has been associated with adverse effects on maternal health and pregnancy outcomes, including hypertension [52, 53].

Biochemical zinc deficiency after bariatric surgery has been supported by multiple studies (see Table 2). There are wide variations reported in the post-operative prevalence of reduced serum zinc levels possibly due to the type of hospital involved in bariatric surgery, the length of postoperative follow-up, patients' socioeconomic factors, and the use of different cutoff levels in defining a biochemical nutritional deficiency.

Table 2. Prevalence of zinc deficiency after specific bariatric procedures

Surgery*	Post-op period	No. of patients	Zinc deficiency	Reference
RYGB	6 months	36	61.11%	[55]
RYGB	12 months	100	36%	[54]
RYGB	12 months	86	34.88%	[56]
SG	12 months	50	30%	[56]
SG	12 months	200	5 %	[57]
SG	12 months	28	10.7%	[58]
BPD/DS	6 months	24	83%	[66]
BPD/DS	18 months	180	38.3%	[65]

*RYGB: Roux-en-Y Gastric Bypass; VSG: Vertical Sleeve Gastrectomy; BPD/DS: Biliopancreatic Diversion/Duodenal Switch.

In a study from University Hospital in Memphis, TN [54], 100 individuals had serum zinc levels examined at 1 year after surgery. In this study the prevalence of zinc deficiency was 36%. In a more recent study [36], 36 individuals had serum zinc levels measured six months after Roux-en-Y gastric bypass. The prevalence of zinc deficiency in this long term study was 61.11%. In an additional study from Switzerland, Gehrler et al found that 34.9% of patients were zinc deficient after Roux-en-Y gastric bypass, compared to 30% after vertical sleeve gastrectomy, in postoperative follow up at 1 year [55].

Due to its restrictive nature, vertical sleeve gastrectomy is thought to result in less frequent and less severe postoperative nutritional deficiencies compared to gastric bypass surgery. Despite the absence of surgically induced malabsorption in individuals undergoing vertical sleeve gastrectomy, there is emerging literature suggesting that zinc deficiency is common after sleeve gastrectomy. This is important due to the worldwide rise in the utilization of vertical sleeve gastrectomy, as mentioned above. There have been short term as well as long term studies of the prevalence of zinc deficiency after vertical sleeve gastrectomy. In a one year follow up of 200 individuals after vertical sleeve gastrectomy, van Rutte et al reported a 5% prevalence of zinc deficiency [40]. In a similar study, Saif et al. reported a 10.7% prevalence of zinc deficiency at one year follow up of 28 individuals after vertical sleeve gastrectomy. These results were confirmed by an additional 4 year follow up that showed a 14.3% prevalence of zinc deficiency in these patients [56].

In contrast to vertical sleeve gastrectomy, the worldwide performance of adjustable gastric banding has rapidly declined in recent years. Studies evaluating zinc deficiency after this bariatric procedure are scarce. In 30 patients who underwent laparoscopic adjustable gastric banding, at 6 months after the surgery Boyuk et al found that the postoperative zinc levels (500 ± 130 ng/ml) were statistically significantly lower than the preoperative zinc levels (740 ± 230 ng/ml) [59], but this decline did not result in clinical zinc deficiency.

Biliopancreatic diversion with duodenal switch may be superior to other bariatric procedures in terms of weight loss, as supported by recent meta-analyses [58-60]. However, biliopancreatic diversion is also associated with more frequent postoperative nutritional disorders due to increased malabsorption, and so this bariatric procedure is generally restricted to super-morbidly obese patients (body mass index of ≥ 50 kg/m²) for whom greater weight loss is required [61, 62]. An increased risk of zinc deficiency has been reported in individuals after BPD/DS by Botella and associates [63]. The authors report results from 180 patients with BMI decreasing from a preoperative value of 52.9 ± 7.7 kg/m² to 30.8 ± 5.2 kg/m² after surgery. In this group, 38.3% of the patients were found to have low serum zinc levels at 18 months follow up. In a similar study, when evaluating 24 patients after BPD/DS, Salle et al reported that 83% and 91.7% of the patients had biochemical zinc deficiency at 6 months and at 12 months postoperatively [64].

MECHANISMS OF ZINC DEFICIENCY

Postoperative Bariatric Surgery

Despite multiple studies describing low zinc levels and its outcome, the exact underlying mechanisms involved in the development of postoperative zinc deficiency are not well understood (see Table 3). Three major factors can influence zinc status in humans: reduced zinc intake, reduced zinc absorption, and increased losses.

An important factor associated with zinc deficiency early after bariatric surgery is reduction in dietary nutrient intake due to decreased gastric capacity. Studies that evaluated food records found that zinc intake was inadequate in almost all patients presenting for follow up after bariatric surgery [65-67]. In addition to this decrease in total zinc intake, zinc

ingestion related to use of meat products (beef, lamb, and oysters) can also be decreased due to low tolerance [68-70] or the use of a low fat, high protein sources in the postoperative diet.

Table 3. Proposed mechanisms for development of zinc deficiency after bariatric surgery

• Reduction in total food intake due to decreased gastric capacity
• Poor tolerability of food with high zinc contents
• Post-operative vomiting
• Substantial reduction in intestinal absorption surface
• Dumping syndrome with rapid oral-cecal transit
• Altered bioavailability of zinc in obesity
• Small intestinal bacterial overgrowth
• Concomitant administration of iron and copper
• Altered compensatory mechanisms post-operatively

Zinc absorption takes place mainly in the duodenum and initial portions of the jejunum. These portions of the intestine are bypassed during Roux-en-Y gastric bypass which may result in a substantial reduction in intestinal absorption surface and, in turn, less absorption capacity. In a recent study evaluating the patients who underwent Roux-en-Y gastric bypass surgery, percentage zinc absorption from a standard diet decreased significantly from 32.3% to 13.6% at 6 months and to 21% at 18 months after surgery [71]. Although vertical sleeve gastrectomy restricts the volume of the stomach without bypass of the small intestine, it also leads to accelerated gastric emptying. Subsequently, rapid gastric emptying might promote nutrient deficiencies [72], as observed in a recent study describing increased fecal excretion of fatty acids which induced moderate malabsorption [73]. Due to the high frequency of postoperative iron deficiency, frequent administration of iron supplements may also increase a patient's risk of zinc deficiency due to competitive interactions for uptake of these minerals [74].

Post-surgery zinc deficiency could also be due to a defect in compensatory mechanisms. Zinc is subject to strong homeostatic regulation via the gut and liver. Zinc absorption is affected by zinc status and absorption efficiency is inversely correlated with the zinc level in the body [75]. Zinc is mainly excreted by the intestine through intestinal and pancreatic secretions. It is believed that zinc homeostasis can be altered by malabsorptive surgery. This result may be partly due to excessive loss of zinc arising from secondary diarrhea after these surgeries [76]. A major compensatory mechanism in the presence of biochemical zinc deficiency (e.g., greater intestinal absorption and reduced excretion of zinc) can therefore be reduced [77].

Zinc and Small Intestinal Bacterial Overgrowth

Small intestinal bacterial overgrowth after gastrointestinal surgery has long been known to lead to cyanocobalamin or vitamin B12 deficiency. Our group has further examined the role of small intestinal bacterial overgrowth in development of thiamine or vitamin B1 deficiency. The results of our studies support small intestinal bacterial overgrowth as a potential mechanism to explain postoperative micronutrient deficiencies [78]. These studies have also expanded upon prior reports of increased serum levels of folate (which is produced by upper intestinal bacteria and then absorbed into the serum) in individuals with small intestinal bacterial overgrowth [79] by comparing elevated serum folate levels with abnormal breath hydrogen levels in individuals examined by glucose-hydrogen breath testing after Roux-en-Y gastric bypass surgery.

Small intestinal bacterial overgrowth can result in malabsorption as a result of the effect of gut flora on intestinal absorptive functions. In normal individuals, colonization of bacteria in the proximal gastrointestinal tract is in low concentrations. However, in individuals with small intestinal bacterial overgrowth, the flora of the proximal gut can be changed toward higher concentrations of colonic-type anaerobic bacteria that can induce fermentation.

Small intestinal motility and the migrating motor complex are important defense mechanisms against upper gut bacterial overgrowth, likely due to passage of bacteria into the colon [80]. Bariatric surgery may disrupt these defense mechanisms. The creation of a shorter small intestine may result in less time and less intestinal surface area for absorption of bile acids, gastric acid, and pancreatic enzymes.

These post-procedural disruptions may alter small intestinal motility and could permit bacteria to have prolonged access to intestinal chyme further promoting bacterial overgrowth [81].

A clinical diagnosis of upper gut bacterial overgrowth can be difficult since patients can present after bariatric surgery with non-specific abdominal symptoms including cramping abdominal pain, abdominal bloating or distension, increased flatulence, or diarrhea. These abdominal symptoms can overlap with symptoms of malabsorption caused by lactose intolerance, fructose intolerance, or surgical bypass of small intestine.

Based upon prior reports of B vitamin deficiencies induced by small intestinal bacterial overgrowth, our group examined the association between zinc absorption and small intestinal bacterial overgrowth [82].

This study was a retrospective review of 452 patients who underwent Roux-en-Y gastric bypass surgery from 1999 to 2005. As a marker of small intestinal bacterial overgrowth, an elevated serum folate level (a serum level above the upper limit of normal for the serum folate assay) has a reported specificity of 79%.

All patients were identified who had measurement of serum folate levels. Levels of serum folate were available in 230 patients, while 172 patients had determination of both serum folate and serum zinc levels. This study involved 199 females and 31 male patients with an average age of 46 years-old (range was 21 to 68 years old). The mean body mass index was 53 kg/m² with a range of 40 to 100 kg/m².

For results involving the total 230 patients, 145 had elevated serum folate levels supporting 63% prevalence for upper gut bacterial overgrowth. As shown in Table 4, among the 172 patients who had measurement of both serum folate and serum zinc levels, in 54 patients with normal serum folate levels, 43 had normal serum zinc; among 118 patients with

elevated serum folate, 78 had low serum zinc (Chi-squared 2x2: $P < .001$), supporting upper gut bacterial overgrowth as a mechanism for biochemical zinc deficiency.

While these results support upper gut bacterial overgrowth as a mechanism for the development of zinc deficiency after bariatric surgery, in previous studies we showed that treatment of Vitamin B1 deficiency with oral Vitamin B1 supplements requires concomitant antibiotic therapy for small intestinal bacterial overgrowth [78].

This finding suggests that oral zinc supplements may not be fully effective for the treatment of zinc deficiency in individuals who have upper gut bacterial overgrowth after bariatric surgery. Further studies need to be performed to evaluate treatment of small intestinal bacterial overgrowth with antibiotics and the subsequent absorption of dietary zinc.

Table 4. Relationship between serum folate levels and serum zinc levels after gastric bypass surgery*

		SERUM FOLATE LEVELS		
		NORMAL	ELEVATED	TOTALS
SERUM	NORMAL	43	40	83
ZINC	LOW	11	78	89
LEVELS				
TOTALS		54	118	172

*Chi-squared 2X2: $P < .001$.

The high prevalence (52%) of biochemical zinc deficiency in our above study of patients after gastric bypass surgery raised the question of the clinical importance of this finding.

We evaluated 43 patients who underwent upper endoscopy for vomiting, abdominal pain, or bleeding after gastric bypass surgery from May 2007 to May 2008 [83].

There were 40 female and 3 male patients with an average age of 46 years-old (range was 21 to 63 years). In 17 out of 43 (40%) of these patients, there was an abnormal finding at upper endoscopy: gastrojejunal anastomotic stricture (obstruction) or gastrojejunal anastomotic ulcer. In 8 patients with gastrojejunal ulceration, 66% of the patients had low serum zinc levels. In patients who had elevated serum folate levels, there was no increased risk of gastrojejunal ulceration (Chi-squared 2X2: $P=0.53$), but there was a strong trend toward decreased serum zinc levels ($P = .16$) supporting a role of upper gut bacterial overgrowth in developing zinc deficiency. Based on these results, in this subset of patients after Roux-en-Y gastric bypass surgery, zinc deficiency was associated with formation of marginal gastrojejunal ulceration. Since zinc is an important component in the biosynthesis of Cu-Zinc superoxide dismutase, these findings support the importance of bioavailable zinc in tissue homeostasis. There was no evidence to support the notion that marginal gastrojejunal ulceration was caused by small intestinal bacterial overgrowth.

CLINICAL MANIFESTATIONS AND PREVENTION
OF ZINC DEFICIENCY

Potential Clinical Screening Methods

Due to its high prevalence after bariatric surgery, clinicians should be aware of the risk of zinc deficiency and the need to monitor bariatric patients closely. Regular follow-up and clinical recognition could be important for preventing the development of zinc deficiency in this susceptible postoperative group.

The pivotal role of zinc in cell growth and differentiation can explain the substantial effect of zinc deficiency in tissues with a rapid cell turnover, particularly the skin, gastrointestinal tract mucosa, gonads and immune system. As summarized in Table 5, numerous signs and symptoms have been associated with zinc deficiency. Mild zinc deficiency is associated with depressed immunity, dysgeusia (loss of taste), anosmia (loss of smell), impaired wound healing and decreased spermatogenesis. Severe zinc deficiency may be characterized by growth retardation, alopecia, acrodermatitis, severe infections due to altered immune function, and cognitive decline [51, 84-91].

Ongoing clinical and biochemical assessment of zinc status poses many challenges because, despite the large number of methods proposed, all of the available methods have problems that alter their validity. The search for a reliable indicator of zinc deficiency has been problematic because the effective regulation of zinc homeostasis buffers the functional response to dietary deficiency and excess.

Table 5. Common clinical manifestations of zinc deficiency

• Alopecia	• Stomatitis
• Delayed wound healing	• Dysarthria
• Acrodermatitis	• Nystagmus
• Growth retardation	• Hypogonadism
• Anorexia	• Dysgeusia
• Anosmia	• Immune dysfunction
• Impaired concentration	

According to a recent systematic analysis by Lowe et al, plasma zinc concentration is the only biomarker that can be used to measure zinc status in individuals and reflects zinc intake [92, 93]. However, there are various confounders of plasma zinc concentrations and clinical interpretation should be made while keeping in mind these limitations and constraints. Measurement of 24-hour urinary zinc excretion may be useful in monitoring response to zinc supplements, but their role in detecting low zinc levels is not clearly validated. Lowe and associates concluded that zinc concentration in erythrocytes, polymorphonuclear cells, and mononuclear cells and platelets, as well as plasma alkaline phosphatase levels, do not appear to be useful biomarkers of zinc status according to the current evidence. Other bioactive measures such as the exchangeable zinc pool [94] and endogenous zinc measurement with the

use of stable isotopes [73] are potential biomarkers. Clearly, there is a clinical need to develop reliable biomarker of zinc status, and more high quality studies are required to assess the effects of the current indices in a variety of populations included postoperative bariatric patients.

Zinc Deficiency after Bariatric Surgery

As described above, there is a high prevalence of micronutrient deficiencies after gastric bypass surgeries. The extent of and severity of micronutrient undernutrition is related to the extent and severity of disruption of normal gastrointestinal anatomy and physiology [95]. Post-operatively, it is presently recommended that all individuals who have undergone Roux-en-Y gastric bypass or vertical sleeve gastrectomy receive daily micronutrient supplementation consisting of two multivitamin supplements (to include iron, folic acid, thiamine, and Vitamin B12), 1500 mg of elemental calcium, and at least 3000 international units or 75 mcg of daily vitamin D for minimally the first 3 to 6 months after surgery [96]. Currently, there are no recommendations with regards to oral zinc supplementation in this susceptible postoperative population due to insufficient data, although multivitamins containing mineral supplements routinely include zinc. There is some evidence to support routine screening for zinc deficiency after malabsorptive bariatric surgical procedures and to support the use of routine supplementation following biliopancreatic diversion with duodenal switch [65, 97]. Again, the dosage of zinc in such patients needs to be further studied.

The high rates of zinc deficiency are concerning and this diagnosis should be considered in all post-operative patients who present with the signs and symptoms summarized in Table 4. The recommended “optimal” dose of oral zinc supplementation for individuals with symptomatic zinc deficiency has varied in the available literature and there is no present consensus. The concentration of zinc in oral multivitamins used in supplementation programs after bariatric surgery may not be sufficient as described above. While treating with oral supplements, potential risks of interactions with other trace minerals such as iron must be considered. The timing of the zinc in relation to the meals is also important as its absorption is 60% during fasting but decreases to 20 to 30% when taken with a meal [98]; indeed many patients take their multivitamin supplements with a meal after bariatric surgery. The Recommended Dietary Allowances for zinc is 11 mg/day for male and 8 mg/day for female in healthy, non-operative adults who are 19 years or older according to the Institute of Medicine of the National Academy [99]. However, the doses of zinc needed to replete zinc in patients with zinc deficiency, when zinc intake and absorption are reduced by significant alterations in the anatomy and physiology of the gastrointestinal tract, are unknown.

Ruz et al studied the effects of zinc supplement in 56 morbidly obese patients undergoing bariatric surgery [73]. These patients were divided into two groups of 27 and 19 patients respectively. One group received standard supplement with daily dose of 7.5 mg/day while the other group received double the dose, e.g., 15 mg/day. Despite supplementation, the mean zinc levels decreased from 87.2 µg/dL to 80.3 µg/dL in the group receiving standard zinc supplements and from 87.2 µg/dL to 80.5 µg/dL in the group receiving double zinc supplements. Based on their data, the investigators suggested routine supplementation of the zinc, but at a higher dose of 40 to 60 mg/day. Zinc absorption can plateau at a dose of about 20 mg/day [100], but in situations of zinc malabsorption, doses as high as 60 mg/day of zinc

are advised. There is a need for additional studies to determine the appropriate dose and monitoring of the patients with varied levels of biochemical zinc deficiency after different types of bariatric surgery.

CONCLUSION

The prevalence of obesity is rising worldwide. Bariatric surgical procedures remain a major option for treatment of medically-complicated obesity. Currently, only about 1% of the morbidly obese population is being evaluated for this surgical strategy. With an expected future rise in the prevalence of obesity and the popularity of bariatric surgeries, the worldwide total number of bariatric surgeries will likely rise. These bariatric surgical procedures are not without complications and nutritional deficiencies including zinc deficiency remain significant clinical concerns. Bariatric patients who have zinc deficiency are at risk for developing a myriad of symptoms.

The most common symptoms of zinc deficiency include delayed wound healing, dermatitis, cognitive impairment, hypogonadism and recurrent infections. This susceptible postoperative population has a high prevalence of biochemical zinc deficiency, even prior to bariatric surgery. These risks further increases after bariatric surgical procedures especially if there has been insufficient screening for and treatment of zinc deficiency, both pre-operatively and long-term post-operatively. Bariatric surgical procedures that include a restrictive component with less malabsorptive component may develop lower rates of zinc deficiency in the short term period.

However, long term follow up of postoperative bariatric patients show that other mechanisms may be important for the persistence of zinc deficiency, sometimes overwhelming the use of oral zinc supplements. Our studies support the concern that small intestinal bacterial overgrowth may induce malabsorption of oral zinc. This is a potential mechanism for persistent zinc deficiency in patients after bariatric surgery receiving oral zinc supplements. Clinicians should maintain increased suspicion for the presence of small intestinal bacterial overgrowth in those patients with persistent zinc deficiency following bariatric surgery.

To date, there are no recommendations based on high quality clinical studies either for postoperative screening of serum zinc or for the routine daily supplementation of zinc after bariatric surgery.

Doses of oral zinc supplements higher than the RDAs are required to supplement those individuals who develop zinc deficiency after bariatric surgery. Currently, there are many gaps in our understanding including the exact mechanisms involved in pre-operative and post-operative zinc deficiency, the potential need for screening and routine supplementation after different bariatric procedures, and to what extent low serum zinc levels can be normalized in postoperative patients. It will be important in this field of research to find the answers to these questions by completing high quality translational studies.

Chapter 393

THE PERCEPTION OF THE BODY: QUANTITATIVE METHODS FOR SELF-EVALUATION OF THE BODY IN PLASTIC, RECONSTRUCTIVE AND AESTHETIC SURGERY

Paolo Persichetti, Annalisa Cogliandro and Mauro Barone*

Department of Plastic Surgery,
Campus Bio-Medico University of Rome, Italy

ABSTRACT

The human search for beauty is to be conceived both as an aesthetical attitude and as an expression of personal satisfaction and balance between self and external appearance. The body image can be mainly understood in two ways: how our body is seen by others, and how our body is seen by ourselves. The perception of our body as an external entity represents an objective point of view, while the perception of our body as we see it deals more with a subjective point of view. Cosmetic surgery should address only the objective dimension of body image, and therefore should correct the imperfections that actually exist as well as underlie any relational or social difficulty of the patient. The patient's point of view must be made scientifically valid and provable. The only means to achieve this goal are questionnaires which can filter patients' perception about their own bodies. In conclusion, we believe that every surgical technique and medical action which ground on patient requests need to be combined with a specific questionnaire which can assess the actual result and success rate on that specific patient.

INTRODUCTION

Aesthetic Surgery is the surgical specialty that aims to correct or improve imperfections, whether congenital, acquired by illness, traumatic or parapsychological events such as aging, including, even, those surgical procedures requested by normal patients, who need to improve their self "exterior." [1] Therefore it differs from Reconstructive surgery, however, it deals with the treatment of morphological alterations that underlie a pathological condition; in the specificity of their respective areas, cosmetic surgery and Reconstructive surgery both belong to Plastic Surgery. There has been an increase in cosmetic surgeries performed in recent years, in line with the orientation of modern society in which the wellbeing of the individual is strongly based on one's physical appearance. There is continual research on beauty, which is not only intended as an aesthetic ideal but also as an expression of personal satisfaction and a balance between personality and external appearance. [2] While the value of plastic surgery has never been doubted, the same cannot be said for cosmetic surgery. Hostility toward cosmetic surgery has been lessened by a new concept of health. Previously, health was considered an absence of illness, but the World Health Organization later defined health as physical, psychological, and social well being. Therefore, the reformed concept of health acquires a subjective value that individuals place on themselves and their bodies [3].

Medicine and cosmetic surgery are developed in the wake of a philosophical and literary reflection. Medical discipline deals with the search for the aesthetic body through exalting and correction of the human form in order to reach a corporeality that respects the standards of beauty, classically or commonly understood.

The search for beauty and its value has always been a topic of discussion. Modern and safer plastic surgery techniques as well as aesthetic medicine have brought back the question, making beauty possible, accessible and democratic. Being beautiful will end up becoming an imperative from which a new and subtle discrimination comes out: natural beauty is more precious than artificial beauty. Concerning the clinical practice, a relevant question is whether an objective indication exists for cosmetic surgery [4].

In the context of a world dominated by the image, physicality plays an important role, medicine and cosmetic surgery procedures are performed in order to improve the patient subjective perception of physical appearance and often personal self-esteem.

The body image can be understood in two ways: our body seen by others and our body seen by ourselves. The perception of our body from the outside is an objective point of view, while the perception of our body seen by ourselves is a subjective point of view [5].

Cosmetic surgery should address the objective component and then correct the defects that are actually existing as well as possible underlying relationship problems of the patient.

The patient's point of view must be made scientifically valid and provable. To achieve this the only means are questionnaires which can filter the patient's perception about their own bodies.

Plastic Surgery in Modern Society

Depending on the ages and historical moments society develops ideas and patterns in relation to the body, influencing individuals. The social-anthropological interpretation,

therefore, will vary with the context in which the analysis is expected to lie, as you may be faced with the implementation of interventions that, at first glance, are technically quite similar but which, however, have different meanings depending on the patient who suffers them, and the expectation of the meaning given to the surgical procedure.

It is certainly possible to find in patients undergoing cosmetic surgery different individual motivations, however, they are always related to appearance conformed to a certain social model or to a vision of the same.

The appearance of the body responds to the staging, by social actors, of all the investments that they bear in order to make the body presentable, and at the same time represented. [6] These two aspects are inseparable and in this sense the body, understood as an individual product, embodies the dynamics of the incorporation process by which the individual organizes the symbolic mode of the society in which he lives.

Cosmetic surgery can be interpreted as a genuine care where the body becomes a complex of desires and modular, replaceable, affordable parts.

Behind the appearance of the cure lies the birth of a new non-ethics of the parties, to which the body is not only divided and subdivided, but is also driven to a real marketing that responds to the demands of a global market. [7] In this sense, the anthropological discipline is called into question once again with the purpose of its social reassignment towards which it cannot escape.

Surgical procedures on the buttocks, abdomen, thighs or on the face would give answers to the anxieties associated with aging and thus promise a body that remains or becomes imperishable, young in appearance, and ultimately, healthy-looking. These needs cannot be compared to social needs, they are wishes of individuals which take on a collective dimension and conformist aspects; people are absolutely convinced of the fact that plastic surgery makes possible what seemed impossible before, that is to “re-construct” a body that is free and fulfilled. In this idea of an embodiment by means of a surgical intervention there are paradoxical aspects on how to complete something, or better conclude a route of a body that is considered to be incomplete, because perceived as deficient or otherwise forced by some limitations and for which a real life comes at the cost of a “counter-life” [8].

In cosmetic surgery with its “beauty industry professionals”, [9] you can guess a dual corrective purpose: that of the outer body, but also that of the spirit. The correction of body parts through surgery can become an absolutely essential condition for those social actors, investing on a narcissistic desire of self, who seek and find (they say) in the “new” body a renewed sense of well being and reconciliation with the world. Not surprisingly, once the surgery is performed, patients generally report feeling better and perceiving an improvement in their quality of life.

From the analytical point of view this desire relies on a model of corporeality that can be properly defined as “up to standard”, [10] that is a realization of conformity; This conforming to socially accepted norms is proposed by contemporary societies in relation to a state of psychological well-being, that combined with the notions of “being better” and “healthy” can actually be realized through the exploitation of cosmetic surgery [11].

It necessarily finds the forefront of those who truly “correct” the body, because this task is ultimately delegated to a “social caste of specialists”, cosmetic surgeons, who are in charge to “repair” the bodies, and then to ensure an adjustment to the stereotypes of beauty through surgery, which itself becomes a “surgery of conformity.” Retrofitting by the hand of the

surgeon in charge, is creating a “corrected body” in the sense of an act that is lawful and legitimate in terms of the powers of a social space.

The bodies appear to have become the privileged places of realization of the idea of “taking care” of themselves, an encouragement towards the fulfillment of self and others. Today, the body appears as the only possible anchor, dream of liberation and freedom, a way to be able to plan and invest in ourselves; it becomes an expression of will, the drive of desire, the search for renewed identity, a young and healthy appearance. The body is renewed and transformed in step with technological innovation: this is a neo-positivist image where achievement of perfection is a reassuring goal.

Quantitative Methods for Self-Assessment of the Body

The use of questionnaires is the only way to analyze scientifically and objectively the perception that the patient's own body and how he would like to see it changed.

The BREAST-Q, [12] a new patient-reported outcome instrument, was developed with strict adherence to recommended international guidelines to address the lack of instruments for breast surgery patients. There are currently four modules (breast reduction, augmentation, reconstruction, and mastectomy without reconstruction), each of which includes a core of independent scales assessing six domains (satisfaction with breasts, satisfaction with overall outcome, psychosocial well-being, sexual well-being, physical well-being, and satisfaction with care). In the original development study, all scales were found to fulfill criteria for good measurement.

For women, breast cancer remains a common and dreaded experience; it is normal for a diagnosis of breast cancer to evoke grief, anger, and intense fear. The options of breast conservation and reconstruction give women a new sense of control over their treatment and are quite successful in helping women feel comfortable with their bodies again [13].

In our experience we deal with two types of women with breast cancer: young women (aged less than 40 years) and older women (aged over 60 years). Our dialogue with these patients is radically different, in fact, younger women not only want to heal from the disease, but their concern is also paid to the aesthetic postoperative consequences, expecting that the plastic surgeon should be giving due attention to the reconstruction in order to maintain the outward appearance of the breast as much as possible unchanged. Healing for a woman of young age can only be achieved when the appearance of the breast is the most aesthetically satisfactory. For older aged women healing consists principally in cancer eradication, while reconstruction is something that some patients still refuse. Currently we are conducting a study on our breast unit and we are analyzing the results of the last ten years of heterologous reconstruction in patients with breast cancer. Patients who underwent breast reconstruction after demolition procedures have a much higher quality of life than patients who have not completed their breast reconstruction [14].

The assessment of quality of life before and after surgery cannot be based on personal considerations of the attending physician, but must necessarily be expressed through objective studies, such as evaluating through the BREAST-Q.

The surgery should be chosen not only based on the anatomical part to be rebuilt but also according to what the patient expects. [15] The concept of modern surgery is no longer the sake of science that deals with a “disease to treat” rather than a “patient to be cured,” but it is

a psycho-surgery, by which we aim to make the most satisfied patients in the shortest possible time; this concept is achievable only if the satisfaction of the patient and the improvement of quality of life can be assessed from a scientific and objective point of view.

We agree with Coriddi M. et. al. [16] saying that there is increasing pressure to use validated survey instruments to demonstrate patient-reported outcomes, as the implementation of evidence-based medicine continues to grow in everyday practice. We think that the use of the BREAST-Q questionnaires should become part of the routine in the management of candidates for an intervention of mammary and reconstructive surgical procedures, they should be discussed and compared according to the needs of the patient [17].

This new set of FACE-Q [18] instruments can be smoothly incorporated into research and/or clinical routine practice to better understand the recovery process and quality of life impact of facial aesthetics procedures as well as what patients think about their decision to have surgery. [19] Plastic surgeons seek to continually improve aesthetic outcomes alongside the patient experience.

Every man is born with specific physical features that make him unique, especially the face, which more than anything else defines the person. We like to divide the face into three anatomical planes that correspond to three different aspects of the patient: the upper or brain, which includes the forehead and eyes, corresponds to the function of thought and imagination and translates to the degree of our rational understanding of the world. The mid-plane or social-emotional, with cheekbones and nose, is linked to the feelings and values and expresses our intuitive perception of the world. The lower or instinctive, jaw and mouth, corresponds to the functions of nutrition and indicates our interest in the concrete.

When the patient wants to change one of these three parts, he wants to change a specific part of himself.

Many people feel a deep psychological malaise which they try to overcome or at least lessen with surgery, which acquires therefore also a therapeutic value. Of course, these arguments are not valid for all patients because the considerations vary from person to person and it is difficult to answer them in absolute terms. In any case, the therapeutic indication of a correction considered “aesthetic” and also the same lawfulness of the procedure from a legal point of view, always starts from the idea of improving the physical and mental well being of the patient and to accept the freedom of the people who want to “change” their appearance.

The representation and the objectification of the body becomes almost an obsessive and prominent part of society today, increasing attention towards plastic surgery, identified as the most powerful tool that corrects dimorphism, alterations in body perception, improves irregularities and may even intervene in exaggerated attitudes, such as hyper-correction of aging, making the dream of eternal youth come true. It is not so uncommon, then, that the patient desires a correspondence between the image of the body “exterior” and of the body “interior”, which in his mind is still young. The problem occurs, however, with the awareness that this process of “change” and the natural aging and as such must be accepted [20].

If it is true that these considerations can be applied to all areas of the body and the face, which is obviously something more than an anatomical area, because the face characterizes the individual and profoundly affects social relations. Therefore it is common to request a change mainly as a result of the progressive changes that aging causes, but are these discomforts and proper framing issues exclusively aesthetic issues?

All these points must be objectified and evaluated and the FACE-Q is a good way to get answer, [21] like other questionnaires used for other parts of the body. [22] We already use

the BREAST-Q to objectify the perception that our patients have of their body before and after surgery. The FACE-Q should therefore be applied both in aesthetic medicine practices and in those of cosmetic surgery [23].

The DAS59 has been designed and developed to meet the need for an objective measure of the spectrum of psychological distress and dysfunction that is characteristic of disfigurements, deformities and aesthetic problems of appearance. The DAS59 is highly sensitive as a measure of change following treatment with large and significant preoperative-postoperative reductions in full-scale and factorial scores of patients treated for facial features or body/sexual features. The DAS59 offers benefits for patient selection in both cosmetic and reconstructive plastic surgery and in the evaluation of outcome. [24] As the global population grows, the percentage of those over 60 will escalate disproportionately. Their needs will become an ever more dominant feature of public policy and healthcare provision. Older adults' appearance is often removed from cultural ideals and stereotypes of beauty, often seen as synonymous with "youth." This has seen older adults' concerns about appearance and body image somewhat sidelined in practice and in research. This study investigates the extent to which self-consciousness of appearance is associated with distress and dysfunction in those over 60 years old. Furthermore, we contrast the extent of this phenomenon in two European nations, UK and Italy, and consider the direct impact and interaction of cultural context and participant gender. The Italian translation was sound, with acceptability in the Italian-speaking sample and acceptable internal consistency scores for full-scale and subscales. ANOVA analysis demonstrated that for overall adjustment, and all subscale scores, the Italians were more distressed about their appearance than UK comparators. Moreover, there were significant differences between Italian women and men, with Italian women more distressed than Italian men overall, and also general self-consciousness, sexual self-consciousness, and social self-consciousness subscales [25].

Currently we are carrying out a protocol subjecting all patients who undergo a cosmetic surgery of any anatomical region to our original Italian questionnaire. [26] This study aims to analyze the levels of information and awareness of patients requesting cosmetic surgery using a questionnaire completed by patients before surgery. The questionnaire is the original result of a collaboration between the Department of Plastic, reconstructive and cosmetic surgery and the Institute of Philosophy of Scientific and Technological Activity of the Campus Bio-Medico University of Rome. We analyze the quality of the information given, the expectations and motivation of the patients who decided to undergo surgery, the degree of patient awareness about the proposed operation, and the aim of the required consent for cosmetic surgery. [27] We published a pilot study that defines the results of the questionnaires obtained from patients only preoperatively. We propose to apply the questionnaire preoperatively and postoperatively in all patients who undergo cosmetic surgery at our institution, and we would like to translate our questionnaire in multiple languages.

CONCLUSION

The only way to evaluate from an objectively valid point of view of the patient, his motivation for surgery, the level of awareness before the surgery, the degree of satisfaction after surgery, improving the quality of view and change in the perception of his body, is the

quantitative analysis of responses obtained through a questionnaire. We believe that any surgical technique and any medical action which is made on a patient needs to be combined with a specific questionnaire which can assess the actual result on the patient. All scientific work on plastic surgery requires a questionnaire on quality of life and the perception of the body, to be considered valid by any magazine of international impact.

Chapter 394

LEADERSHIP, ETHICS, AND THE ADOPTION OF EVIDENCE BASED MEDICINE AMONG LEADERS OF INTERNAL MEDICINE AND SURGERY

Ronald Bogdasarian*

The Commonwealth Medical College, Scranton, PA, US

ABSTRACT

Background: Leadership, ethics and the adoption of evidence-based medicine (EBM) are interrelated components of modern medical care. In today's medical world, cost-effectiveness, patient safety and outcomes are paramount. EBM is at the forefront while engrained medical traditions are scrutinized at an increasing rate. This shift in paradigm requires strong leadership. With this complicated arrangement, exploration and comparison of the concepts of leadership, ethics, and EBM in two prominent areas of healthcare, general internal medicine and surgery, is a valuable exercise.

Objective: The primary objective of this work is to review the literature on leadership and ethics in the field of internal medicine compared to surgery and examine how they affect the adoption of EBM. The secondary objective is to identify aspects of leadership, ethics, and the implementation of EBM within internal medicine and surgery that may serve to improve the other discipline.

Design: A review of the literature using Pubmed and Embase was performed. Keywords included leadership in internal medicine, leadership in surgery, ethics in internal medicine, ethics in surgery, evidence-based medicine in internal medicine, and evidence-based medicine in surgery.

Setting: The Commonwealth Medical College, Scranton, PA.

Results/Conclusion: The study identifies multiple similar qualities of leadership in internal medicine and surgery, especially the broad use of transformational leadership. While the less tangible qualities of charisma and personality are recognized, leaders who are willing to educate colleagues and work to solve problems with the healthcare system are required to generate acceptance of EBM by a healthcare team. Differences in leadership style that might affect the adoption of EBM exist between internal medicine and surgery. Internal medicine depends more on the culture of the team, while surgery

* Corresponding Author's Email: RBogdasarian@tcmc.edu.

depends more on the influence of powerful individual leaders. Other differences included internal medicine's greater appreciation for patient participation in care while surgical leaders are acknowledged most for technical skill and the ability to teach. Notably, both internal medicine and surgery ethical leaders refrain from conflicts of interest, especially regarding increasing financial responsibilities, in order to maintain personal morals and the trust and respect of their healthcare teams. Ethical leaders in internal medicine place the patient's autonomy above the decisions of the medical team. Ethical leaders in surgery make appropriate decisions regarding heroic and end-of-life care. There are inherent differences between internal medicine and surgery that challenge the cross-over of leadership qualities from one discipline to the other. However, the differences in leadership style that do exist provide potential areas of improvement for each.

Keywords: leadership, medicine, surgery, ethics, evidence based

BACKGROUND

In this review of the literature we explore the differences between internal medicine and surgery with regard to leadership and leadership's interface with ethics and the adoption of evidence-based medicine (EBM). We examine our findings and search for lessons that may benefit the art and practice of each discipline, particularly regarding the adoption of EBM. Today, a large portion of the leadership in healthcare is derived from non-physician, organizational management. This chapter will focus on physician leadership and ethics and their roles in the adoption of EBM.

A large body of literature describes two major systems of leadership—transformational and transactional leadership. Transformational leadership results in an environment in which team members feel personally connected to the goal. This system is often utilized in situations requiring broad change [1]. Transactional leadership is suited for use in emergency situations in which grand change is not necessary. It relies on rewards and punishments [2].

Much of the literature on leadership in medicine and surgery focuses on the team and a stepwise process, conforming more with the transformational system [3,4,5].

First, the leader, utilizing qualities such as charisma, confidence, wisdom, and inspirational communication, instills a common goal and culture within the team [6].

Second, while an active member of the clinical team, the physician leader is an excellent delegator and ensures that all members feel comfortable and important.

Third, the leader properly assesses performance and ensures completion of tasks.

Fourth, he or she constantly reflects in order to improve performance. These are the basics of medical leadership and are generally shared by internal medicine and surgery leaders. How, though, do leaders of medicine and surgery differ? Can these qualities cross over to improve leadership in the opposite discipline, and can these improvements lead to better implementation of EBM?

Strong ethics are essential for proper healthcare and leadership. Physicians are often presented with challenging ethical dilemmas which require familiarity with the fundamentals of ethics. Both internal medicine and surgery leaders have a strong grasp on the principles of autonomy, beneficence, nonmaleficence, justice, the intricacies of informed consent, durable power of attorney and healthcare proxies [7,8]. Are there other emphasized areas of ethics in

healthcare today? How do ethics, cost-effective medicine, and EBM interrelate in the practice of healthcare leaders?

Today, EBM has a permanent place in medical practice and increasingly directs medical care. Many healthcare practitioners lament the loss of control over their abilities to make their own healthcare decisions. For this reason, knowledge of physician leadership and how it differs between internal medicine and surgery should prove valuable to improve the art and practice of medicine, healthcare professional satisfaction and patient outcomes.

MATERIALS AND METHODS

Pubmed and Embase were used to review the literature. Keywords included leadership in internal medicine, leadership in surgery, ethics in internal medicine, ethics in surgery, evidence-based medicine in internal medicine and evidence-based medicine in surgery.

RESULTS

Leadership in Internal Medicine:

In addition to the transformational stepwise process of goal oriented leadership within the team environment, the literature presents multiple qualities of the strong internal medicine leader. Heavily emphasized is acceptance of change which has clear implications for the adoption of EBM over non-evidence supported traditional practices [9,10,11].

Further highlighted is teamwork, especially in interdisciplinary teams with emphasis on the patient as a team member [12,13]. Two 2014 articles from the *Journal of General Internal Medicine* state that internal medicine leaders are inspired by their patients [14,15]. Another 2014 article from the *Journal of General Internal Medicine* indicates that shared decision-making by the physician and patient, when evidence-based options and uncertainty are discussed, can lead to improved patient satisfaction [16].

A 2007 article from the *American Journal of Medical Quality* asserted that great internal medicine leaders direct attention to problems with the system, rather than with individual employees when an error causes harm to a patient [17]. This indicates that when a leader is dissatisfied with the implementation of EBM by a co-worker, he or she should examine the system in place meant to ensure the proper practice of EBM. This re-evaluation of the system, rather than a reprimand of a single employee or colleague, may help to improve the overall adoption of EBM.

Ethics in Internal Medicine

The literature expands upon the basic ethical principles mentioned in the background section. In a world where clinical leaders are becoming members of administration, conflict of interest and issues regarding financial honesty and fraud are paramount for the ethical leaders of internal medicine [18,19,20]. A 2013 article from the *Journal of Taibah University*

of *Medical Science* notes multiple qualities of the internal medicine ethical leader, including “altruism, accountability, excellence, duty, honor and integrity, and respect for others.” These leaders resist “abuse of power, sexual harassment, conflicts of interest, professional arrogance, physician impairment, and fraud in research” [21].

In order to accomplish the implementation of EBM through transformational leadership, in which a healthcare team becomes personally connected to the goal, the leader in internal medicine must be ethically sound. Conflicts of interest and fraud in research may undermine a healthcare team’s trust in the evidence behind EBM and lead to reduced acceptance of new medical practices.

As explained previously, including the patient in decision making leads to increased patient satisfaction. Including the patient as an active member of the team was considered to be ethically essential for the internal medicine leader [14,15]. Likewise, transparency and honesty with patients are also indispensable qualities of the internal medicine ethical leader [22].

Evidence Based Medicine in Internal Medicine

Much of the literature agrees that, in order for an internal medicine team to accept EBM, a culture of acceptance of change is paramount. This culture of change, resulting in the adoption of evidence-based practices, occurs in locations with strong hierarchal leadership and strong opinion leaders [23,24]. These leaders are often seniors with time to reflect and learn. In other words, in order to be a leader, one cannot be overwhelmed by the daily routine such that he or she cannot engage in novel medical learning [25]. These individuals must also be willing to “do what it takes to remove obstacles” to quality improvement such as poorly supported traditional beliefs and approaches. These leaders must be willing to take the time to share information and new knowledge on EBM and do so in a clear, concise manner [26].

Leadership in Surgery

Much of the literature on leadership in surgery states that confidence and speed pertaining to technical skill is essential for the leader in surgery [27,28]. A surgeon who proves the worth of EBM through his or her own practice is more likely to convince others to train using similar practices.

The abilities to teach and mentor are highly regarded qualities of the surgical leader. A 2013 paper from the *International Journal of Surgery* takes this a step further, explicitly differentiating surgery from internal medicine. The authors comment that great surgical leaders take routine processes, such as check lists, and transform them into rich learning experiences [29]. In surgery, leaders who are able to employ this strategy in their support of EBM should be more successful.

The literature also highlights the ability to communicate in a democratic fashion in order to accomplish tasks with those with different ideals, personalities, and even goals [30,31]. A 2014 study from *Health Affairs* states that humility is a key trait of the most respected surgical leaders. These leaders, while maintaining goals, are able to accept failure and are willing to communicate and cooperate with others to correct errors [32,33]. Surgical leaders

are also respected for “incisive, imaginative, [and] innovative scientific minds” [34]. One 1997 article from *Acta Neurochirurgica* discusses at length the importance of awareness to one’s surroundings, objectives, and problems [35]. Interestingly, a 2013 article from the *Canadian Journal of Surgery* discusses the importance of personal development, especially in personal health and exercise in surgical leaders [36]. While not as prominent in the literature as technical skill and the ability to teach, these additional qualities may add to the recognition of the surgical leader and his or her ability to engage co-workers in the adoption of EBM.

In a glimpse into the minds of what influences surgical residents, a paper from *Aesthetic Plastic Surgery* describes “informal leadership”. This concept refers to respect that is earned through consistent success in difficult situations, and can only be bestowed by peers. This “informal leadership” is distinct from one’s title, or “formal leadership”, which can be acquired by a surgeon who does not possess innate leadership qualities [37]. Surgical residents often gravitate to these surgeons who describe personal anecdotes of exciting, heroic experiences. While some may argue that these anecdotal experiences are exciting because they inherently diverge from the common, algorithmic EBM, these leaders are in a position to reaffirm the importance of EBM in everyday practice.

Ethics in Surgery

As in internal medicine, the literature on ethics in surgery recognizes the good leader’s resistance to conflicts of interest [38,39]. Leaders in surgery are becoming more involved in administration, the financial aspects of care, and funding for research. The literature indicates that leaders in surgery must also avoid unethical practices in order to maintain co-workers trust for the implementation of EBM.

The literature on ethics in surgery also emphasizes the leader’s ability to decide when heroic care is appropriate [40,41]. End-of-life care and heroic care are often technically difficult, expensive, and controversial. An in depth discussion on the specifics of EBM in this area of medicine is beyond the scope of this chapter. However, surgeons who are experienced and are capable of making difficult medical decisions, while remaining sensitive to the families of patients, are in a strong position to lead the adoption of EBM in this area.

Evidence Based Medicine in Surgery

Much literature focuses on the surgical leader’s acceptance of EBM, which indicates that there is greater resistance to change and the adoption of EBM in surgery than in internal medicine, at least regarding engrained, everyday practices [42]. Again, the ability to teach is one of the most highly regarded qualities of leaders in surgery and is essential for the propagation of evidence-based practices. The literature emphasized the open-mindedness of surgical opinion leaders who are called upon to accept EBM and show expertise and technical skill in its delivery. The literature suggests that opinion leaders are the driving force in a hierarchical system that is the structure in which attending and resident surgeons continue to learn. Thus, highly respected local opinion leaders as advocates for EBM is of utmost importance in surgery [43,44,45].

DISCUSSION

As discussed in the background, the key components of leadership and ethics and their connection to the adoption of EBM are similar between internal medicine and surgery. There are, however, many notable differences.

Leadership

The literature indicates that leaders of both internal medicine and surgery tend to utilize a transformational, structured approach. Leaders generate a clear goal that members of the team identify with which supports a culture of agreement and productivity. Leaders put team members in positions to succeed and feel important. Leaders evaluate success as the team progresses. Once a goal is achieved, leaders reflect in order to improve for the future. This transformational method of leadership is well suited for the movement towards the EBM model.

Differences in leadership qualities between internal medicine and surgery include the following. Leaders of internal medicine accept the patient as a member of the team and are even “inspired” by their patients more often than their surgical counterparts. An essential quality of leadership in surgery is technical skill which can only be said for a small subset of internal medical physicians who perform a large volume of procedures [46]. Notably, the ability to teach is more commonly emphasized in the literature on surgical leaders than on internal medicine leaders.

These differences likely arise from the inherent differences between internal medicine and surgery. Internal medicine physicians traditionally spend more time conversing with patients in order to gather large volumes of information for management of multiple problems. These physicians receive praise as leaders for their ability to educate, comfort, and include patients in decision making. In surgery, much of the time spent with a patient is in the operating room where technical skill and outcomes are regarded as most important. While surgeons are still respected for good communication with patients, the emphasis is on the operative result. It is important to stress that discussions with patients should include education about evidence-based options for care. This results in the greatest patient satisfaction.

Due to the inherent differences between medicine and surgery, it is difficult to identify many areas of leadership that could cross over to the other discipline and improve the acceptance of EBM specifically. That said, possibilities areas for improvement include the following. In surgery, the technically savvy opinion leader has great potential for generating a more powerful culture change and should not be satisfied with simply providing an example of EBM to his or her peers. In internal medicine, while educating his or her colleagues and residents, the internal medicine leader should strive to create rich learning experiences from the repetitive daily routines that are part of EBM. Ultimately, all leaders should work to enhance the acknowledged strengths of their discipline’s leadership style if they wish to increase the adoption of EBM.

Ethics

Many similarities exist regarding the ethics of internal medicine and surgery leaders. Both leaders have a strong grasp of the core principles of ethics, including autonomy, beneficence, nonmaleficence, justice, the proper use of informed consent, durable power of attorney and healthcare proxies.

Increasingly, both medical and surgical leaders are more involved in administration, finances, and funding for research. Recent literature focuses on the leader's refrainment from conflicts of interest that are possible in these positions. Internal medicine and surgery leaders must embrace this ethical pillar. Trust and respect from the healthcare team are necessary for change and the acceptance of EBM.

An important area of consideration regarding ethics is end-of-life care and heroic care. The literature indicates that internal medicine leaders focus more on the physician-patient relationship, while surgery leaders focus on when and when not to operate. While many surgical leaders do enjoy strong relationships with their patients during end-of-life care, the literature indicates that this is an area where surgeons could learn from their medical counterparts in order to strengthen this relationship. It is unclear, however, if this could enhance the adoption of EBM in surgery with regard to this area of healthcare. Alternatively, a focus on the willingness to make difficult decisions in end-of-life care is acknowledged as an important, albeit controversial, area in need of change toward EBM for both internal medicine and surgery leaders.

Evidence Based Medicine

The literature agrees that leaders in both internal medicine and surgery are at the forefront of the adoption of EBM. The manner in which EBM is encouraged differs, however.

The literature indicates that internal medicine leaders must create culture changes within their teams. Strong opinion leaders who are not overwhelmed by daily practice are required to generate these changes. Surgery is similar in that respected opinion leaders are essential, but there is less emphasis on culture change as a process.

The difference is subtle. Opinion leaders in internal medicine are important, but it is the cultural environment of the team that is most crucial. The literature indicates that surgery employs a powerful hierarchal system. In this system, the leaders have earned high regard due to their skills and ability to teach. These surgical leaders are able to influence the practice of their followers more so than the surgical culture does. As described previously, the surgical opinion leader may enjoy increased success in his followers' implementation of EBM if he works to generate culture change.

CONCLUSION

Most leaders in both internal medicine and surgery rely on the transformational form of leadership. The adoption of EBM by a team fits this leadership model well and is utilized by both groups of leaders. While the basics of leadership are similar, many of the differences

between internal medicine and surgery leaders are due to the inherent differences in the respective disciplines. Even so, many leaders in each field bridge the gap and look to their colleagues in the other field for areas of potential improvement.

Key to the success of these physician and surgeon leaders is the sense of teamwork. They are confident and capable within their own realms of practice to the extent that they are able to diversify and enjoy aspects of the other group. While there are many specifics of leadership that can be improved upon by each group of leaders, such as patient centeredness for surgeons, teaching style, and technical skills for physicians and decisions regarding end-of-life care, it is most important to recall that physicians and surgeons are all members of the same team. All physicians and surgeons should share a common culture of teamwork so that colleagues may practice the most proven forms of medicine and patients may enjoy the best outcomes possible.

It is important to repeat that the material from this chapter comes from a literature review. The differences in leadership style, ethics and use of EBM between internal medicine and surgery were retrieved based on their relative presence in the literature. Although the literature may emphasize certain areas of leadership more in one discipline, this does not mean that leaders in the other discipline are not strong in that area.

Weaknesses of this review include the following. We did not differentiate among leadership in practice size or style or academic or community environment. We did not explore the topics of gender or race. We did not discuss non-physician leadership or the relationship between clinical leaders and administration. Healthcare costs, patient safety and outcomes are among the pre-eminent issues of healthcare today. The strongest of clinical leaders should have the ability to connect administrative leadership with the clinical work force in order to facilitate a relationship that benefits the three parties involved: the healthcare organization, clinicians, and patients. In this light, clinical leaders are more frequently assuming administrative rolls [47,48]. In this review of the literature, the author attempted to withhold opinion.

ACKNOWLEDGMENT

I would like to acknowledge Bridget Conlogue of The Commonwealth Medical College Library for her vital contributions to this chapter.

Chapter 395

APPLICATION OF DA VINCI[®] ROBOT IN GENERAL SURGERY: A COST ASSESSMENT

Ioannis D. Gkegkes¹ and Christos Iavazzo²

¹First Department of Surgery, General Hospital of Attica “KAT”, Athens, Greece

²Gynaecological Oncology Department, Christie Hospital, Manchester, United Kingdom

ABSTRACT

The utilization of robotic assisted surgical techniques represents a novelty in the field of general surgery. Moreover, the development of robotic technology facilitated the realization of complex operations both in hepatopancreatic and in colorectal surgery. However, the elevated costs of the robotic assisted surgery, in comparison to the other minimally invasive procedures, mainly the laparoscopic ones, make the application of robotics in general surgery expensive and not an everyday surgical technique. The present evidence reveals that robotic surgery, under specific conditions, has the potential to become cost-effective. Large number of cases, presence of industry competition and multidisciplinary team utilization are some of the factors that could make more reasonable and cost-effective the robotic assisted technique.

The evolution of robotic technology applications in surgery during the last decade has facilitated the realization of a great variety of operations in various surgical fields [1]. The robotic assisted technique has an important position among the other minimally invasive methods in general surgery. Several are the main advantages of robotic assisted surgery, such as three dimensional view of the operating field, low intraoperative blood loss, precision of movements due to elimination of surgeon tremor, utilization of wristed instruments that improve dexterity and facilitate suturing, have made possible even the most complicate operations such as robotic pancreaticoduodenectomy [2-4]. In contrast to the above mentioned advantages, the absence of tactile feedback of the surgeon and the cost are the main weak points of the robotic technique.

Nowadays, the only commercially available robotic equipment (da Vinci[®] Surgical System) is characterized by elevated cost, including cost of acquisition, training and

equipment-instrument cost, as well as that of maintenance of the robotic system (with an annual service contract, over 100,000 US dollars). This high cost can explain the reasons that decreased the widespread use of robotic assisted surgery [4]. According to van Dam et al., in order to amortize the initial capital for the acquisition of robotic devices, the technique should be applied on more than 300 surgical procedures per year for a period longer of 7 years, equivalent to an amount of over 1,000 Euros per patient [4]. As a result, it can be easily understood that the robotic technology refers exclusively to surgical centers with large volume of patients in order to achieve the per case charges as low as possible. The robotic instrumentation that has increased cost of acquisition (almost over 1,500 Euros per instrument) as well as a limited number of uses (10 lives per instrument) represents another financial burden [5]. Moreover, the reimbursement to the hospital for utilization of the robot is in direct correlation with the type of health insurance and the health system itself, favoring the countries without universal health coverage

The introduction of innovative and less invasive technologies in surgical fields has been adopted with great difficulty from the health care systems as a consequence of the lack of data and of the high costs (acquisition and maintenance) of every novel equipment [6]. In the current finance situation, where the major part of the European economies and a portion of the rest of the world are facing difficulties to sustain the already present health structures, doubts could be raised in the attempts to introduce new and highly expensive technique such as robotics as the new standard of care without the presence of strong evidence of significant cost effectiveness and the comparison of minimally invasive methods to standard surgical techniques. Though cost related studies are complicated to be organized, it is essential that all parts involved, society and doctors, should comprehend the impact of the cost of robotics.

Robotic assisted surgery specifically requires equipment of elevated cost as result of the novelty and the high specialization of the utilized devices [5, 7]. The high cost of acquisition (over 1 million Euros) as well the expensive maintenance costs (almost 150,000 Euros /year) are obstacles that should be overcome. Van Dam et al. has suggested that the costs of robotic equipment could be amortized, if the health care systems permit the application of robotic equipment on elevated number of patients [4]. Furthermore, the absence of competition in the market of robotic equipment, especially after 2003, is one of the most important factors that maintain high the costs of robotic instrumentation [8]. More specifically, in 2003, the merge of the only two existed companies in the market of robotic devices was achieved, creating monopoly conditions.

The operating time is another essential reason that may cause great variations on the total surgical costs. Even though for private health structures the length of the operating time is not an issue, for public health systems, which are financed by the government's budget, every penny must be carefully spent. The setup of the robotic equipment, which is significantly longer compared to either the laparoscopic or the open one can increase the cost, however, it was shown that this time can be substantially improved when the surgical team is well trained [6]. Furthermore, the operative time is related to the experience of the surgical team. The type of surgical operation, as well as the surgeon's capability and experience are factors that influence considerably the learning curve [4]. In addition, the costs are in correlation with the learning curve and are considered as an additional cost caused by the fact that surgeons already went through a training program for both laparoscopic and open technique [9]. Nevertheless, it should be mentioned that an effective way to decrease the costs related to

learning curve is the presence of great volume of patients and the necessity of virtual reality simulators [10, 11].

Minimal invasive techniques have revealed to have an edge over laparotomy for the management of patients in a wide spectrum of pathologies [12, 13]. Keyhole incisions offer various advantages over the open surgical method, such as decrease of both post-operative pain and recovery time, less post operative complications, reduced blood loss, better cosmetic result. In particular, robotic techniques have a positive impact on specific patients' categories, such as the reduction of operative costs and of hospital stay in elderly or morbidly obese patients. According to some studies, the total cost between both open and laparoscopic technique do not present statistically significant difference [14, 15].

The extent of hospital stay has an important influence on the total charges of hospitalization. The limited hospital stay is a principal characteristic of both robotic and laparoscopic approach as it is expected in comparison to the open method [5]. Therefore, the decreased number of hospital days can amortize part of the increased operative costs of the minimal invasive techniques. Besides, the expenses of hospitalization are also in strait correlation with the category of health care system and the type of health care structure [4, 16]. Differences between countries, private or public sectors render complex any approach in order to evaluate those cost data. Regarding the comparison of robotic procedures to laparoscopy, several studies claim that over hospital stay the robotic surgery seems to have a slight financial advantage over the standard laparoscopy [17]. Nevertheless, currently, it appears that laparoscopy is a most economic approach among the other minimal invasive methods.

As presented in Table 1, the greater part of the studies referred to gastric fundoplication and showed that robotic is more expensive in comparison to laparoscopic technique. Despite the cost of acquiring the robotic devices, professional charges, operating room costs, surgical equipment costs present great variation in the included studies. Such a cost could be minimized if we also take into consideration the decrease of the hospital stay, the sooner return to normal patient's activities, the reduction of blood loss and the decrease on conversion rates to laparotomy. Also, by improving the robotic training of all personnel, the surgical time could be further reduced and as consequence favor the use of minimal invasive techniques.

The utilization of robotics in almost every surgical field could be thought, in the future, as a valuable tool in common surgical practice. In order to realize this fact, both operative costs and unnecessary charges should be eliminated. The formation of specialized robotic units operating on great number of cases per year, the reduction of operating time per procedure by specialized training on robotic approach, the decision for early discharge of the patients when that is possible and the minimization of the number of instruments used per operation are some of the first steps that could be done in this direction. An additional proposal to minimize the cost is the multiple-use of the robotic equipment by multiple surgical specialties, good training of all the team members implicated while the acquisition of the robotic devices could be made through research funding or even charities.

Table 1. Robotics in general surgery: costs related to equipment and peri-operative outcomes[†]

First author, Year [ref]	Type of operation	Number of patients (%)	Total costs	Operative charges	Non-operative charges	Robot cost included (Y/N)	Surgical equipment costs	Operating room costs	Length of hospital stay (days)	Conversion to laparotomy (%)	Duration of surgery (min)	Blood loss (mL)

The implement of robotic technology in operations of general surgery represent a novelty that may influence both the surgical treatment of numerous pathologies and the post operative outcomes. The robotic assisted surgery has serious possibilities to evolve in a cost-effective technique especially in centers with large number of cases, in spite of the undeniable elevated costs of acquisition and maintenance. Having as intention to increase the use of this surgical technique, it should be utilized not only on clinical treatment of patients but as well for the surgical training of all residents. The possible future industry competition in correlation with the technological development may steadily reduce the cost of the robotic equipment, making robotics a more cost-effective and affordable technique.

Chapter 396

THERAPEUTIC POTENTIAL OF ADIPOSE-DERIVED STROMAL CELLS IN WOUND HEALING, ANTI-AGING, AND PLASTIC SURGERY

Changyue Xue and Guo Li*

The State Key Laboratory of Oral Diseases,
National Clinical Research Center for Oral Diseases,
West China Hospital of Stomatology, Sichuan University, Chengdu, China

ABSTRACT

Stem cells are undifferentiated cells with important properties for self-renewal and differentiation. Adipose-derived stem cells (ASCs) have many advantages, such as accessibility and abundance, compared to other kinds of stem cells. Regeneration therapies using ASCs have received much attention in the treatment of various dermatological diseases. In previous studies, ASCs were shown to have antioxidant, whitening, and wound-healing effects in the skin through secretion of various growth factors and by activating fibroblasts. There is an abundance of literature supporting the efficacy of ASCs in both aesthetic and reconstructive cases. In dermatology, there are also many studies on the effective application of ASCs, such as improved retention in autologous fat transplantation, antioxidant action, and whitening effects. In this chapter, we will summarize the therapeutic potential and clinical applications of ASCs in wound healing, anti-aging, and plastic surgery.

Keywords: adipose-derived stem cells, wound healing, anti-aging, plastic surgery

INTRODUCTION

The ability of stem cells to self-renew, to secrete trophic factors, and to differentiate into a multitude of cell types has allowed for the development of more flexible cell therapies to

* Corresponding Author's Email: vicentguoli@hotmail.com; Fax: +86-28-85582167.

redefine the classic “autologous tissue transplant” and offer more customizable treatment options. Recent advances in regenerative medicine, in particular the discovery of multipotent, easily accessible stem cells such as adipose-derived stem cells (ASCs), have provided opportunities for using autologous stem cell transplants in regenerative therapies. Compared with bone marrow-derived mesenchymal stem cells, ASCs are particularly useful, as they can be easily harvested with minimal donor site morbidity and have broad differentiation potential. In addition, ASCs have higher yields and greater proliferative rates in culture. ASCs are not only precursors to adipocytes, but also multipotent progenitors to a variety of cells including osteoblasts, chondrocytes, myocytes, epithelial cells, and neuronal cells. This discovery has created the potential to treat a variety of tissue defects from a single, easily accessible autologous cell source.

ASCs have been shown to play a significant role in anti-aging and skin regeneration by forming tissue consisting of hypodermis, dermis, and epidermis. Recent studies also have shown the utility of ASCs in improving wound healing, describing their ability to regenerate soft tissues and their remodeling capacity provided by their unique cytokine and growth factor profiles (Figure 1). There have been many clinical applications about ASCs for compensation of skin defects, wound healing, and plastic surgery. The purpose of this chapter is to summarize the utilization of ASCs in wound healing, anti-aging, and plastic surgery, and to describe the current limitations of ASC treatments with regard to developing translatable clinical therapies. Understanding the current status of clinical ASCs treatments and defining the challenges ahead may bring us closer to achieving desired outcome while minimizing unwanted side effects with these therapies.

Figure 1. Paracrine effect of ASCs in anti-aging and skin regeneration.

APPLICATIONS OF ASCs IN WOUND HEALING

Background

Wound healing is a complex chain of events involving interactions between different cells and tissues, and tissue repair is a lengthy process. The ultimate goal for tissue

engineering is to regenerate skin so that the complete structural and functional properties of a wounded area can be restored to the levels before injury [1]. To accelerate skin regeneration, many skin tissue engineering techniques such as the use of various scaffolds, cells, and growth factors, have been researched [2]. However, only a subset of tissue functions can be restored with existing tissue engineering techniques.

The purpose of tissue engineering is to heal and regenerate injured organs using a combination of cells, cytokines, and biomaterials. The limited availability of human cells capable of self-renewal and differentiation into multiple cells is a barrier for expansion and development of regenerative medicine. Stem cells and progenitor cells provide a potential approach to this dilemma.

In Vitro Studies and Murine Studies

Mesenchymal stem cells (MSCs) are an attractive cell therapy source for the regeneration of damaged tissues, as they are capable of self-renewal and can differentiate into various cell lineages [3]. In cutaneous repair, MSCs can significantly accelerate wound closure, exhibiting increased re-epithelialization, neovascularization, and regeneration of skin appendages [4]. However, several studies have claimed that the effects of MSC therapy are unremarkable in the absence of scaffolds or stimulators [5]. Interestingly, ASCs have surface markers and gene profiles similar to MSCs, and their soluble factors are more sufficient [6]. Because they are conveniently isolated compared with MSCs and show extensive proliferative capacities *ex vivo*, ASCs hold great promise for use in wound repair and regeneration.

The most abundant and accessible source of adult stem cells come from adipose tissue; ASCs are available in liposuction aspirate [7-9]. Despite its rapid translation to clinical practice, the mechanism of its function is not well characterized. It was initially hypothesized that immature stem cells can migrate to the damaged area, differentiate into the cell type of the injured tissue, repopulate the diseased organ with new healthy cells, and subsequently repair the tissue (building-block function). However, the levels of grafted cells and their survival rates are too low, i.e., < 5%, to be therapeutically relevant [10-12]. Importantly, much of the functional improvement and inhibition of injury afforded by stem cells can be achieved by treatment with cell-free conditioned media derived from ASCs [13]. Thus, it can be deduced that ASCs may exert their beneficial effects not only by direct cell-to-cell contact, but also by complex paracrine actions (manager function) in addition to building-block functions.

Earlier studies have already shown that ASCs have a positive influence on wound healing, as they are attracted to the wound site and influence wound healing process via paracrine mechanisms as well as fusion and differentiation; for example, into keratinocytes, fibroblasts, endothelial cells, sweat glands, sebaceous glands, and hair follicles [14-17]. Additionally, some basic fibroblast growth factor (bFGF), vascular endothelial growth factor (VEGF), and human growth factor (HGF)-positive ASCs were detected in the wound bed. bFGF is one of the most important growth factors in wound healing because it affects cell proliferation, matrix deposition, and angiogenesis [18]. VEGF is one of the key factors that promotes vasculogenesis and angiogenesis [19], and is considered to play an indispensable role in myogenic differentiation [20], wound healing [21], and many other processes [22]. HGF is another potent proangiogenic factor that induces cell migration and proliferation and

inhibits apoptotic cell death of endothelial cells [23]. Prior studies also suggested that transplanting ASCs induces neovascularization and improves blood flow to ischemic tissue in animal models [24,25]. Furthermore, ASC-conditioned media (ASC-CM) increased the secretion of type I collagen from dermal fibroblasts as well as stimulating fibroblast migration in in vitro wound-healing models. In addition to the in vitro evidence, ASCs have also been shown to be effective in wound healing in animal models. Topical administration of ASCs prominently reduced the wound size by 34% and accelerated the re-epithelialization at the wound edge. Similar to ASC treatment, ASC-CM treatment also accelerated wound healing in laser-induced burn animal models.

Shokrgozar et al. supplemented collagen scaffolds with ASCs and showed improved epidermal regeneration in burn wounds compared with the control group in ten rats [26]. The surface area of the wound and histopathological findings regarding the formation of dermis and epidermis on the scaffolds supplemented with ASCs were reported. Loder et al. studied the effects of isolated autologous ASCs, fat, ASCs and fat, and phosphate-buffered saline grafts on burns of twenty mice [27]. There was a significant decrease in wound surface area in all groups compared with controls, but not when compared with each other. Groups with ASC treatment and mixed groups showed a significant decrease in wound depth apoptosis. Karimi et al. reported significant increases in fibroplasia and collagen remodeling and a decrease in the surface area of wounds after treatment with ASCs compared with fat grafts in thirty mice [28]. The differences in eschar thickness, inflammatory cell counts, epithelialization, and angiogenesis, however, were not significant.

Murine studies have shown histologic improvements in angiogenesis, collagen organization, and neuropathic pain. There is a lack of randomized controlled trials and quantitative analysis supporting the efficacy of ASCs in burn healing. However, this emerging therapy shows great potential.

Clinical Studies

Human ASC (hASC) therapy has also been successfully applied to wound injury treatments. In 2012, Collawn et al. confirmed that ASCs accelerated wound healing in an organotypic graft culture model [29]. Park et al. showed that spheroid grafting of hASCs treated with low-level light irradiation can enhance ischemic wound healing [30]. Furthermore, Song et al. generated v-myc-expressing hASCs as a long-term sustainable stem cell model for promoting wound healing [31]. Other studies have also found that transplantation of ASCs can promote regeneration of expanded skin, which confirms the effectiveness of ASCs in treating wounds in human models. The applications of ASCs for wound healing are widely recognized as a promising tactic in the future [32]. Existing evidence suggests that ASCs may be useful for improving the survival of diabetic skin flaps [21, 33]. Recently, the effectiveness of ASCs in improving the viability of skin flaps in non-diabetic mice was demonstrated in a study by Lu et al. [34], in which they injected ASCs locally at the flap pedicle and found a nearly two-fold increase in the surviving area compared with a flap without ASC administration. Furthermore, emerging works [35] have shown that the healing of diabetic wounds can also be improved by implantation of ASCs. However, it is still unclear whether topical applications of ASCs could improve the viability of diabetic skin flaps, which represent a more complicated pathophysiological condition and lacks an

effective clinical intervention. Hypoxia amplifies the paracrine effects of ASCs by enhancing the secretion of growth factors [33, 36]. For example, ASCs improved the perfusion in hindlimb ischemia induced by the ligation of femoral arteries, and hypoxic culture conditions enhanced the function of ASCs [37]. Because inflammation and oxidative stress near the wound area in the skin evokes an oxygen deficit, the wound-healing effects of ASCs were investigated in relation to hypoxia. As expected, the secretomes of ASCs cultured under hypoxic conditions shrunk the wound area considerably compared with those cultured under normoxic conditions. Furthermore, analysis of mRNA and protein expression levels revealed that hypoxia up-regulated several growth factors such as VEGF and bFGF. An inhibition study using neutralizing antibodies of VEGF and bFGF induced delayed wound healing, indicating that VEGF and bFGF at least partially account for the hypoxia-enhanced functionality of ASCs. These results suggest that the wound-healing effects of ASCs are at least partially regulated by secretory factors and are amplified by hypoxia.

Currently, chronic wounds represent a major problem in medical field, as their incidence is continuously increasing because of an aging population and a rise in the incidence of underlying diseases [38]. It is estimated that approximately 2% of the population in industrialized countries may be affected by chronic wounds in their lifetime [39]. Physiological wound healing is a complex biological process proceeding from inflammation through proliferation to maturation. It requires well-orchestrated interactions between mediators, resident cells, and infiltrating cells. Basal keratinocytes and fibroblasts play a key role in this process, as they proliferate and migrate, eventually leading to complete wound closure. ASCs can also contribute to the regeneration process for chronic wounds, as they have the ability to replace damaged tissues [40]. With regard to the treatment of burn scars, histological analysis in human studies revealed that ASCs can increase vascularity, new collagen deposition, and reorganization [41-43]. Studies also reported improvements in mimic features, skin texture, thickness, color [44], and patient satisfaction [45]. The utility of lipofilling as a secondary measure to improve previous treatments is also considered to be feasible. Although the regenerative capacity of ASCs is an alluring concept [46], relatively few human studies detailed the use of ASC-supplemented grafts in burns [47]. Two human studies investigated wound healing in the acute phase. A study by Piccolo et al. [48] showed improved wound healing and fibrosis in some acute and subacute wounds. Although there was a lack of controls, the study had sufficient detail regarding the procedures and adequate follow-up. The case study using ASCs from discarded burn tissue was a small case study that was too difficult to assess, but the cells were shown to possess the same adipogenic, osteogenic, and chondrogenic potential as their abdominally derived counterparts [49-51]. Therefore, they may represent a source of multipotent cells in patients with extensive burns for whom there may not be enough viable tissue to perform subcutaneous liposuction to obtain such cells from non-injured sites. Indeed, as the percentage of total surface area affected by burn injury increases, so does the availability of these ASCs from discarded burn tissue.

Although limited in number, studies detailing the use of ASCs on burn wounds and scars had positive results. Murine studies have suggested that ASC therapy may improve outcomes when applied on a newly acquired burn wound. Although some studies had conflicting results regarding the effects of ASCs on the wound surface area, most concluded that early use of ASC therapy can alter the course of the remodeling phase of healing by decreasing apoptosis and increasing fibroplasias [27, 28].

APPLICATIONS OF ASCs IN ANTI-AGING

Background

As individuals age, the skin undergoes some changes, including anomalous pigmentation, thinning, and loss of elasticity, owing to both genetic and environmental factors. These changes may worsen, turning into precancerous and cancerous diseases. Skin aging, which is mostly characterized by loss of elasticity and generation of wrinkles, has preoccupied human for centuries and inspired us to make great efforts to prevent it, yet it still remains a conundrum. A variety of medical treatments and topical cosmeceuticals have been used to treat some symptoms of photoaging; however, the outcomes have been less than satisfactory. ASCs display multi-lineage developmental plasticity and secrete various growth factors that control and manage damaged neighboring cells. Recently, the production and secretion of these growth factors has been reported to be an indispensable function of ASCs, and diverse regenerative features of ASCs have been reported in the skin. Therefore, ASCs and their soluble factors demonstrated promise for the treatment of photoaging.

As skin is exposed directly to the outside environment, it undergoes not only intrinsic aging, but also extrinsic aging; both are associated with structural and functional changes in cutaneous tissue [52, 53]. Aging damage gives rise to a decline in the amount, lifespan, and function of fibroblasts in the dermis, leading to the appearance of aging; this indicates the significance of fibroblasts in researching mechanisms and further therapies to prevent skin aging. In *in vitro* studies, fibroblasts can be serially passaged until they reach replicative senescence to simulate intrinsic aging [54, 55]. On the other hand, it is widely perceived that ultraviolet rays serve as a major extrinsic factor (approximately 80%) for skin aging; ultraviolet radiation B (UVB)-irradiated fibroblasts have been established as an experimental model in many studies related to skin aging [56, 57].

Biological Basis for Soft Tissue Therapy Using ASCs

ASCs stand out as an upstart in the field of anti-aging, owing to their secretome, which has been identified through proteomics, including transforming growth factor-beta (TGF- β), platelet derived growth factor (PDGF), hepatocyte growth factor (HGF), pigment epithelium-derived factor (PEDF), interleukins, and many antioxidants such as insulin-like growth factor-binding proteins (IGFBPs) and superoxide dismutase 2 (SOD2) [58-60]. ASCs have been proven to communicate with and regulate surrounding cells through a paracrine mechanism; thus, ASC-CM, which not only contains all bioactive components provided by ASCs but also has the advantages of easier storage and safer application over ASCs, has recently drawn much attention. Numerous studies have confirmed that the secretome of ASCs can attenuate the symptoms of photoaging. Kim et al. demonstrated that subcutaneous injection of ASCs can improve UVB-induced wrinkles and increase dermal thickness in mice [61]. Song et al. reported that ASC-CM performed better than ASC co-culture in improving proliferation and converting necrotic or late apoptotic cells to early apoptotic cells in UVB-irradiated HDFs [62]. These results were consistent with that of the present study: ASC-CM increased the proliferative activity and decreased the apoptotic cell ratio of UVB-irradiated HDFs. As

shown in the studies by Xu and Kim et al., ASC-CM prevented HDFs from reaching UVB-induced G1 phase arrest [63], a condition in which proliferation stops, senescence occurs, and apoptosis is triggered through repressing p16 expression [62, 64]. However, further investigation of this and more related markers are required to explain these results. Very few studies have reported on the impact of ASCs on intrinsic aging damage, as Shen et al. demonstrated in a recent study that ASCs can increase SA- β -Gal mRNA expression in co-cultured HDFs from young and old volunteers. As we know, SA- β -Gal has been confirmed to be a reliable biomarker of cellular senescence, expression of both its mRNA and protein increase significantly in senescent cells, as does its enzymatic activity. Shen et al. hypothesized that co-culture of ASCs may accelerate fibroblast senescence [65]; to some extent, this deviated from our results: ASC-CM treatment had no impact on SA- β -Gal activity in serially passaged HDFs in vitro; this may indicate that existing and accumulated damages at the genetic level cannot be easily reversed. The inconsistency in these results may indicate that ASCs do not simply act on HDFs via paracrine growth factors; there may exist a feedback loop between HDFs and ASCs through cell-to-cell crosstalk.

The production and secretion of growth factors is considered an essential function of ASCs; various rejuvenating effects of ASCs on the skin have been revealed⁶¹. For example, it was confirmed that ASCs and ASC-CM stimulated both collagen synthesis and migration of dermal fibroblasts during the wound-healing process [66]. ASC-CM also inhibited melanogenesis by down-regulating tyrosinase and tyrosinase-related protein-1 (TRP-1) expression in B16 melanoma cells [67]. In addition, ASCs and their secretory factors protected dermal fibroblasts from oxidative stress induced by chemicals and UVB irradiation [68]. In a clinical setting, intradermal injection of processed lipoaspirate cells (approximately 20–30% ASCs) induced an increase in dermal thickness and a reduction of wrinkles [69]. This evidence supports the important role of ASCs and their secretory factors in protecting the skin against photodamage. Chronic UV radiation harms human skin, affecting skin tone as well as its resiliency and results in premature aging (photoaging), the symptoms of which include wrinkles, laxity, sallowness, mottled pigmentation, leathery texture, and, in the long run, precancerous (lentigo maligna, actinic keratoses) and cancerous changes. Besides, ASCs may promote collagen synthesis and angiogenesis as well as exhibit protective effects against D-galactose-induced skin aging in mice [70, 71]. These reports indicate the wealth of potential applications of ASCs in the anti-aging industry.

Several studies into the pathophysiology of photoaging have uncovered similarities with certain aspects of chronic wounds [72, 73]. Histologically, photo-aged skin shows significant changes in ECM composition [74]. The collagen component of dermal ECM is responsible for the strength and resiliency of skin and is deeply involved in the pathology of photoaging and wounds.

Antioxidant Effects of ASCs

Currently, a popular topic in dermatology is the exploration of any possible means to counteract the injurious effects of anatomical-functional skin damage. Substances that prevent free radical-induced skin damage are of great interest. Although there are few reports on the antioxidant capabilities of ASCs, some evidence shows that the secretomes of ASCs may have a protective effect during oxidative injury. For instance, interleukin-6 (IL-6) attenuates

epithelial cell death induced by hydrogen peroxide [75]. This evidence suggests that ASCs exhibit an antioxidant effect. However, the underlying mechanism of this protective effect is yet to be determined.

As ASCs are located under the skin, specifically beneath dermal fibroblasts, they may play key roles in skin damage involving oxidative stress. Consequently, the antioxidant effects of ASC-CM on dermal fibroblasts were investigated in an oxidative injury model. In ASC-CM, various antioxidant proteins such as IGF binding proteins, IL-6, PEDF, SOD2, and HGF were examined using proteomic analysis and an enzyme-linked immunosorbent assay (ELISA). A cell-survival assay demonstrated that incubation in ASC-CM protected dermal fibroblasts from free radicals produced by tBOOH and induced morphological changes. Furthermore, activities of both SOD and glutathione peroxidase were enhanced in dermal fibroblasts after treatment with ASC-CM. Cell cycle analysis revealed that ASC-CM treatment reversed apoptotic cell death induced by reactive oxygen species (ROS), as shown by a notable decrease of sub-G1 phase dermal fibroblasts. Recent studies have revealed that ASC-CM inhibited the proliferation of B16 melanoma cells without inducing apoptosis. Even though the mechanisms responsible for the anticancer effects of ASC-CM are yet to be fully characterized, secretory factors of ASCs prolonged the G1 phase in B16 cells (G1 arrest), delaying the progression of cancer. Considering the antioxidant and anticancer effects of ASC-CM, it is reasonable to assume that ASCs play an important defensive role against oxidative stress in the skin.

Potential Applications of ASCs in Photoaging

Sun exposure harms the skin due to the effects of UV radiation. UVA and UVB reportedly alter particular cellular pathways, resulting in several developments. UVB radiation leads to redness of the skin, whereas UVA can penetrate deeper into the dermis where it causes more DNA damage. Exposure to UV radiation has a notable effect on collagen production as well as pigmentation, and is responsible for skin thickening, mottled pigmentation, and wrinkling [76]. However, ASCs protect the skin from UV irradiation, improve wrinkling, and reduce pigmentation.

Anti-Wrinkling Effects of ASCs

Topical application of several growth factors stimulates the repair of photo-damaged skin, leading to new collagen synthesis, epidermal thickening, as well as a clinical appearance of smoother skin with less visible wrinkling [77]. A cell-based treatment using autologous cultured dermal fibroblasts was developed to promote skin texture; the treatment showed relatively optimistic results in clinical applications [78]. Because several growth factors involved in skin repair are secreted by ASCs, and ASCs have characteristics that are similar to fibroblasts, it was hypothesized that ASCs may improve UVB-induced wrinkling. The use of soft tissue fillers containing ASCs to restore volume to depressed areas of skin to maintain a youthful appearance has gained popularity in recent years. Such applications are very popular because of their simplicity, low invasiveness, procedure reversibility, and relatively safe profile. However, as the use of fillers has increased, so has the number of reported

complications. These complications, including vascular compromise and skin necrosis, are mostly significant and permanent.

Whitening Effects of ASCs

Clinically, photo-aged skin is coarsely wrinkled and exhibits associated dyspigmentation and telangiectasia. In Asians, the principal manifestation of photodamage is pigmentary change, rather than wrinkling [79, 80]. Antioxidants inhibit chemical reactions that result in melanin formation, change the type of melanin formed, and interfere with the distribution of pigment and melanosome transfer. Therefore, they are ideal candidates for skin whitening agents. In addition, several growth factors reportedly modulate melanogenesis and are also major regulators of tyrosinase and TRPs [81-83]. Because ASC-CM has potent antioxidant capabilities and contains several whitening growth factors, the whitening effects of ASCs were investigated. ASC-CM was harvested and its inhibitory effects were studied in melanoma B16 cells. ASC-CM treatment attenuated both the synthesis of melanin as well as tyrosinase activity in a dose-dependent manner. To further clarify the underlying mechanisms of the whitening effects of ASC-CM, melanogenic proteins were qualified using western blot analysis. Although expression of microphthalmia-associated transcription factor (MITF) and TRP2 remained unchanged, ASC-CM treatment reduced the expression of tyrosinase and TRP1. TGF-1, a potent regulator of melanogenic proteins, was neutralized by adding a blocking antibody to ASC-CM, and the down-regulation of tyrosinase and TRP1 was almost reversed. Although the exact mechanism responsible for the whitening action of ASCs has not been fully characterized, secretory factors may down-regulate the expression of melanogenic enzymes; TGF-1 plays a key role.

APPLICATIONS OF ASCs IN PLASTIC SURGERY

Background

Recent advances in tissue engineering, especially the discovery of multipotent, easily accessible stem cells such as ASCs, have provided the potential to use autologous stem cell transplants in regenerative therapies. The field of plastic surgery is centered on the restoration and enhancement of the body, and is logically positioned to utilize such new technologies focused on the repair and replacement of diseased cells and tissues [84]. The ability of stem cells to self-renew, to secrete trophic factors, and to differentiate into different cell types has made it possible for the development of more flexible therapies to redefine the classic “autologous tissue transplant” and to offer more customizable treatment options. ASCs are being utilized in a variety of different applications in plastic surgery [85-89], and as our understanding of the basic science of stem cells continues to develop, plastic surgeons should be better prepared for the translational and clinical implications of this progress.

The Biological Basis for Soft-Tissue Therapy Using ASCs

Early work suggests that injecting ASCs into soft tissue or into a defect will not alone produce a soft-tissue fill. A therapeutic strategy must be used to leverage the unique aspects of these cells. One strategy is to use a tissue engineering approach, combining cells stimulated with certain chemical compounds with a matrix or scaffold to “manufacture” an implantable neoadipose construct. Several potential scaffolds combined with cells have been investigated for their utility in soft-tissue treatment. In one example, preadipocyte cells, which are similar—if not identical—to ASCs, were combined with the resorbable material poly (lactide-co-glycolide acid) (PLGA). In this study, although initial results were promising, analysis after 5 to 12 months showed a complete absence of fat and PLGA [90, 91]. A similar study compared the hyaluronic acid sponge, HYAFF 11, with collagen sponges augmented with ASCs. They found that HYAFF 11 was superior to collagen in supporting the differentiation and expansion of ASCs [92].

Clinical Applications

The regenerative potential of ASCs has been confirmed for many years, which has resulted in the advent of techniques such as fat grafting for replacement of soft tissue. The autologous tissue utilized in fat grafting contains a variety of cells, including ASCs [93], which support tissue neo-vascularization [94] and regeneration through the secretion of various growth factors [95]. Cell-assisted lipotransfer (CAL), a technique first described by Matsumoto et al. in 2006, combines aspirated fat with concentrated ASCs to create stem cell-rich fat grafts [96]. This approach resulted in considerable improvements in the survival rates of transplanted fat, with less fat resorption [97] and a decrease in the adverse effects of lipoinjection such as cyst formation and fibrosis (Figure 2). In breast tissue, fat grafting has also been connected with fat necrosis and calcifications, which can complicate breast imaging and breast cancer surveillance [98, 99]. Coincidentally, Yoshimura et al. used CAL in 2008 for cosmetic breast augmentation in forty patients and reported a favorable aesthetic outcome with no major complications [100]. Thereafter, CAL has been used in other studies involving breast augmentation [101-103] as well as for facial lipoatrophy [104, 105] and augmentation during facelifts and facial contouring surgeries, among others [106].

Very recently, a clinical multicenter trial on breast reconstruction with stem cell-enhanced fat grafting after a partial mastectomy was published. Processed ASCs were utilized to enrich the fat graft. Autologous ASC-enriched fat grafting for breast augmentations in a prospective series of twenty patients was also reported by a Japanese group without conclusions about oncological concerns with 9 months of follow-up [101]. Kolle et al. demonstrated significant fat graft survival in human cases after *ex vivo* expansion of collagenase-processed ASCs used for CAL when compared to traditional methods of fat grafting [107]. Alternative ASC therapies have also been explored, including techniques such as stem cell-enriched tissue injections that combine traditional fat grafts and subsequent ASC injections [108, 109]. These preliminary studies showed that ASCs might allow for improvements in the retention and volume-restoration capabilities of transplanted fat, though the applicability of these studies in the United States is limited because of the methods used (enzymatic isolation). A Spanish group’s report showed promising results from combining

ASCs with fibrin glue for treatment of fistulas in Crohn's patients [110]; this study stands in the vanguard as a report on the application of ASCs in clinical practice. Thus, as a feasibility study, this investigation warrants the attention of plastic and reconstructive surgeons. Since the early reports describing a population of ASCs with multi-lineage differentiation potential by Zuk et al. [111] in 2001, our understanding of the molecular biology of ASCs and their potential functional benefits has rapidly gained pace. In 2006, Moseley et al. [112] reported on preliminary results from Japan indicating that combining ASC seeding with conventional adipose transfer for soft tissue fill is beneficial. Studies from their laboratory and ours have begun to uncover the molecular and cell biology underlying this potentially advantageous approach. In essence, early data suggested that ASCs enhance local microvascular establishment when introduced in the therapeutic milieu, providing support to the adipose graft. As such, this early boost in vascular support would buttress the initial take of the graft and minimize long-term atrophy, thereby providing superior maintenance of graft volume fill over time.

Concerns have been raised over the application of ASCs in the form of CAL for breast augmentation after breast cancer treatment. For example, studies have revealed that MSCs increase the risk of metastatic potency in breast cancer cells when the two were mixed and re-implanted [113-115]. While there is little evidence in terms of CAL therapy for breast augmentation post-mastectomy, the American Society of Plastic Surgeons has concluded that fat grafting does not increase the risk of breast cancer recurrence. It appears that ASCs may enhance the growth of active cells without affecting dormant cells, but because more research is needed, the current recommendations are such that CAL therapy should be delayed for reconstructive purposes in breast cancer treatment until there is no evidence of active disease for a period of 7 years [116].

Figure 2. Scheme of cell-assisted lipotransfer. Relatively ASC-poor aspirated fat is converted to ASC-rich fat by supplementing ASCs isolated from the other half of the aspirated fat. The ASCs are attached to the aspirated fat, which is used as a scaffold in this strategy.

Barriers to Clinical Entry

In 2006, Yoshimura et al. described a cell population in the liposuction aspirate fluid; these cells exhibited phenotypic properties similar to those of ASCs harvested in the traditional manner (collagenase) from processed lipoaspirate cells. However, the yield was reduced by a third when comparing to the two approaches [117]. Thereafter, additional studies have been published touting the benefits of non-enzymatic ASC isolation. In 2010, Francis et al. described a method of ASC “Rapid Isolation” in 30 min, which excluded the use of collagenase; however, an obvious disadvantage of this study was the low yield of less than 250,000 cells from a starting volume of about 250 ml liposuction aspirate fluid [118]. Zeng et al. investigated a “rapid and efficient” form of non-enzymatic ASC isolation in which adipose tissue is cut into small pieces and placed in culture flasks with 100% FBS, where the plastic-adherent cells were allowed to grow for several days [119]. One significant disadvantage to this method is the requirement to expand the cell population using calf serum. Most recently, Shah et al. described a form of non-enzymatic ASC isolation by combining the cells of the liposuction aspirate fluid with cells captured from the processed lipoaspirate tissue wash, which is typically discarded prior to collagenase digestion [120]. They observed a significant improvement in MSC-related phenotypic markers and similar adipogenic and osteogenic differentiation characteristics. While their isolation time was cut by one-third, they observed a 19-fold decrease in ASC isolation when compared to the traditional method.

Most convincingly, Kolle et al. showed a clear benefit to CAL over lipotransfer alone. They isolated and expanded ASCs *ex vivo* from human patients, followed by lipotransfer to the arms of the patients with or without ASC supplementation. They demonstrated a 65% improvement in fat graft survival after 4 months in the group with ASC treatment. The major drawback to their experimental model was that in order to achieve these results, 34 ml lipotransfer was supplemented with 6.5×10^8 ASCs, or 2,000 times the physiological level [107]. The approaches of “rapid isolation,” as previously mentioned, demonstrated the ability to isolate ASCs without the aid of enzymatic digestion, but at a cost of greatly reduced yields.

There is promise in capitalizing on the plastic-adherent properties of ASCs as a form of non-enzymatic isolation. Doi et al. The same group that first described the isolation of cells from the LAF, has reported that an adherent column of rayon-polyethylene non-woven fabrics may also be useful for isolating ASCs, though at a lower yield than traditional methods [121]. Further advances in harnessing the plastic-adherent properties of these cells are obviously needed, as Buschmann et al. demonstrated that 30-50% of ASCs remain in suspension after 24 h of primary culture [122].

PERSPECTIVES

Participants

The pharmacology of ASCs and ASC-derived secretory factors that are involved in wound healing, anti-aging, and plastic surgery have been reviewed in this paper. To date, applications of ASCs and their secretory factors have been investigated mainly *in vitro* and in animal models; more clinical trials in humans are needed. Because ASCs and ASC-derived

secretory factors have anti-wrinkling, antioxidant, and skin-whitening effects, they are regarded as promising agents. However, ASCs are difficult both to handle and to commercialize, approaches to overcome these barriers are needed, but many questions remain unanswered. The long-term safety of CAL in previously cancerous areas remains unknown. While we are still uncovering the exact mechanism of stem cell function, whether paracrine or differentiation induced, the discovery of the very abundant ASCs will allow for major advancements in tissue engineering, particularly pertaining to therapeutics. In addition, it may become clear that these therapies will need to be individually tailored if it is found that patients vary in their responses to these cells or the trophic factors they produce. The ultimate answer will likely be achieved by the combined efforts of basic scientists, clinicians, and biomedical engineers.

Chapter 397

SPEEDY AND EASY TECHNIQUES IN FACIAL PALSY SURGERY

A. Di Stadio*

Otophatology Lab, Otolaryngology Department, Mass Eye and Ear,
Harvard Medical School, Boston, MA, US

ABSTRACT

Several techniques are used to treat facial palsy. Some of these techniques show very good results but take a long time to execute or are very invasive.

In our opinion, it's important to first identify the problem, understand what is necessary, and find a solution that is easy and rapid for both patient and surgeon.

In this chapter, the author will discuss the association between the different techniques for achieving symmetry recovery in facial palsy patients.

Presented are the techniques most used in recent years. The author will show in detail their personal surgical technique for the treatment of eye disease and the results in terms of improvement in recovery time. Based on the author's experience, the association between the eye technique and the reanimation of the middle and inferior face is the best option.

In this chapter, the author will show techniques that are simpler and faster to perform in the belief that facility and velocity are advantages for both surgeon and patient. The techniques will be described in a didactic and detailed way, starting from surgical anatomy and covering all surgical technical details. It is the goal for these techniques to be easily reproducible after this primary study.

The goal of this chapter is to show how fast and simple techniques can provide results as satisfactory as, if not better than, more complex techniques.

INTRODUCTION

In history, several methods have been discussed and used to treat the asymmetry of permanent or irreversible facial palsy [1]. Surgical rehabilitation techniques are divided into three categories: physiological, dynamic, and static [2-3]. The physiological method is represented by direct anastomosis and nerve transfer, cross-face, and free-flap re-anastomosis. These techniques were performed with the goal of restoration of the damaged nerve with creation of a “new” nerve. The dynamic method uses muscle transposition. Muscles, innervated to normal functional nerve and deputies of another movement, are transposed to restore movement; examples of this are temporalis and masseter muscle transfer. Static techniques, in contrast to the first two methods, are surgery methods able to correct the asymmetry in static positions only, without a real correction in dynamic movements [4]. Examples include fascia lata suspension or selective myotomies on the face [6].

In this chapter we propose an association with different techniques to obtain facial symmetry. We will explain how to treat the paralyzed eye and smile with fast techniques.

PREOPERATIVE EVALUATIONS

Understanding the problem is the first step to solving it. In a paralyzed face, it is important to focus attention on the eye and smile. For the eye, analyzing the area of scleral exposure (ASE) in sick and healthy eyes is necessary to understand which procedures are useful to treat superior and inferior eyelids. This is a photographic method of evaluation with millimeter paper to capture the sclera in static (open eye) and dynamic (closed eye) action. The normal distance between the upper and lower eyelids in an open eye is 10-12 mm. The ASE system also considers the position of eyelid relative to pupil, which is useful to understand which procedure to use on the eyelid and whether it is necessary to use two different techniques [7].

Figure 1. Example of ASE system. The white portion uses mill metric paper to evaluate the sclera's exposition.

In smile analysis, it is important to consider the “three smile classification”. In terms of how many muscles are involved during the action of smiling, we can identify three different types of smiles: the zygomatic or Mona Lisa smile, the canine smile, and the full teeth smile. Understanding the patient’s smile helps in choosing a surgery technique and its details [8, 9, 10].

Figure 3. Canine smile.

Figure 4. Full teeth smile.

Anatomy per Images

Eyelid: anatomy of the orbicularis oculi muscle (Figure 5a, 5b and 6).

Temporal muscle: Image 7 and 8

Masseter muscle: Image 9a

“Subzygomatic triangle”: Image 9b

Masseter nerve: Image 10

Figure 5a. Eye anatomy frontal view. This muscle is divided into two regions: the orbital and palpebral areas. The palpebral area is further subdivided into the pretarsal (PT) and preseptal (PS) regions.

Figure 5b. ADS (acronym of author's name) palpebral area within the PS and PT regions. The exact position of this muscular structure is easy to establish during surgery because the PT portion of the muscle is directly adherent to the inferior tarsal structure and is immobile with respect to the plane.

Figure 6. Eye anatomy lateral view.

Figure 7. Anatomy of the temporal muscle and insertion on coronoid process, lateral view.

Figure 8. Anatomy of the temporal muscle, masseter muscle, and facial nerve, coronal view.

Figure 9a. Anatomy of the masseter muscle superficial and profund, lateral view.

Figure 9b. Subzygomatic triangle. This triangle is formed by the inferior border of zygomatic arch superiorly, a vertical line through the anterior border of temporomandibular joint posteriorly, and the frontal branch of the facial nerve inferiorly and anteriorly. The masseteric nerve follows a line that begins at the angle of subzygomatic triangle and crosses the midpoint of triangle's base. The nerve is located in the deep muscle belly below a white fibrous fascia. The dominant branch of masseter nerve's course is obliquely within the substance of the muscle for 2 to 3 cm in an antero-posterior direction [27].

Figure 10. Anatomy of the masseter nerve lateral view.

EYE TREATMENT

Superior Eyelid

Indication to Use

Tessier's technique is useful in addition to Labbé's technique because this practice takes temporal fascia during the surgery. A weight implant can be used in single treatment for eye

disease in association with ADS technique and anastomosis. This technique has more risks than Tessier's technique because is an allograft, with more risk of rejection and extrusion.

Upper Eyelid Titanium Weight Implant

(on youtube:www.youtube.com/watch?v=ti2GYGF1sRc)

It is necessary to test different weights before starting the surgery. This procedure is very important to obtain the best result.

An incision is made in the lid crease followed by sharp dissection through the orbicularis muscle to the surface of the tarsal plate. The pocket, where the weight implantation will be placed, is then prepared. This pocket will be the same length as the implant, as in this way is possible to reduce the number of sutures. The pocket will be created at the juncture of the medial and central third of the lid, as in this way we can obtain a completely symmetric eye closure. The prosthesis will be placed over the tarsal plate a few millimeters above the lid margin. The implant will be attached on the tarsal plate with a 6/0 nylon suture in the medial and lateral portion. The reposition of orbicular muscle and suture should be done with 6/0 Vicryl and the eyelid is closed with continue suture [11, 12].

Tessier's Technique

This alternative technique is used to lengthen the elevator muscle of upper eyelid. This technique is a good choice associate to temporal myoplasty because we use temporal fascia to perform the graft. The calculation of the graft's dimension is evaluated with a preliminary eye test. Normally its width is double the palpebral retraction. On times that the graft is token, using an incision in the lid crease performs the same passage of weight implant until reach the tarsus, in upper portion, where the aponeurosis is present we dissect it from the elevator muscle. The aponeurosis is sectioned with a cold scalpel and removed from the muscle. The graft is positioned between the superior edge of the tarsal plate and the inferior edge of elevator muscle and sutured with 6-8 points of 6/0 Vicryl. Suture of the orbicular muscle should be done with separate suture and the skin suture with continue suture [13].

ADS TECHNIQUE

Inferior Eyelid

Indication to Use

If the patient presents ectropion (exposure of the conjunctiva due to a reduction in tension of the anterior compartment of the eye muscle) and lagophthalmus, we perform lateral lower eyelid lifting surgery. For cases with epiphora (eversion of the lachrymal point) and lagophthalmus, we perform medial lower eyelid lifting surgery [7].

These surgical techniques happen at the level of the eyelid. Here, two different techniques are evaluated for specific eye diseases.

Surgery is always performed under local anesthesia.

Figure 11a and b. Evaluation method for identifying the correct surgical technique. This method is useful for Tessier's technique but also for identifying which of the ADS are better to treat the eye disease. We analyze in sick and healthy eyes the distance between the superior eyelid and an imaginary line beginning at the lateral cantus, passing through the pupil, and ending at the level of the medial cantus. The same measure will be used for the inferior eyelid. We identify two different measures, one defined as AB between the superior eyelid and the imaginary line, and a second one defined as BC between the imaginary line and the inferior eyelid. We will analyze the BC measurement in the medial and lateral portion of the eye to identify the correct ADS to use. We will take the AB measurement in the central portion of the eye. The resulting difference between healthy and sick eyes will determine, in the AB measurement, the millimeter for the graft, and in case of BC, which ADS technique is the best to treat the disease.

Figure 12. Eye surgery: Tessier's technique and platinum chain technique.

Lateral Lower Eyelid Lifting Surgery

4 stages: [1] a transcutaneous subciliary incision is made, moving from the lateral canthus down to half of the lower eyelid, [2] a small triangle of skin is resected, a maximum of 3 mm to avoid possible retraction, and [3] a lateral micromuscular PT advanced flap is established, including dissecting the muscle for 6–8 mm, starting 2 mm under the PT portion; lateralizing and elevating the flap; repositioning the PS portion of the muscle with some tension; and suturing at the level of the lateral portion of the PT muscle with 2/3-point 6/0-resorbable sutures. It is necessary to suture the PT muscle to the tarsal portion; specifically, the suture point is on the tarsal cartilage (point 1) in the lateral portion, and points 2 and 3 are attached at the level of the periosteum. At the periosteum, it is necessary to maintain the tension of the lateral part of the muscle, and it is the gold standard to preserve the lower eyelid's correct position in older patients. [4] The suture points are separated by 6/0 polypropylene sutures

Figure 13, 14, 15. ADS technique lateral: line of incision starting from the middle of the inferior eyelid, elevation of the micromuscular flap orbicular muscle, and lateral fixation of the flap with 3 separated points.

Figure 16, 17, 18. ADS technique medial incision in inverted Y shape: in the medial portion of the inferior eyelid, preparation of the micromuscular flap with the orbicular muscle, fixation of the flap at the medial cantus with 4 separated points.

Medial Lower Eyelid Lifting Surgery

3 stages: [1] a transcutaneous subciliary incision is made in the shape of an inverted Y, moving down one third from the medial canthus to the anterior region of the lower eyelid and moving up within 2 mm from the upper eyelid. This incision is necessary to expose the line on the medial canthus. The micromuscular advanced flap will in fact be sutured 1 mm above this line to obtain good suspension of the medial portion of the eyelid (figure 6). [2] A micromuscular advanced flap is made the same way as described for the lateral eyelid technique. Then the PS muscular flap is elevated at the level of the PT portion of the orbicularis oculi muscle and sutured with 3- to 4-point 6/0-resorbable sutures, starting from the medial canthus and working toward the middle tarsal portion of the lower eyelid. [3] Suturing at the level of the medial canthus with polypropylene 6/0 sutures is performed

Smile Treatment

Indication to Use

The choice of temporal myoplasty or masseter/facial anastomosis is based on the surgeon's preference. In this case, in fact, both techniques are valid and offer very good results. General anesthesia is necessary.

Lengthening Temporal Myoplasty (Dynamic Technique)

(on youtube:www.youtube.com/watch?v=fzCi4Het7Q)

Two different approaches are available; the choice is in the function of the necessary lengthening of muscle to join the orbicular muscle.

Upper Head Dissection

Coronal or Monocoronal Lifting approach. The local anesthesia is performed because is also useful to help the dissection. The subgaleal dissection is necessary up to 2 cm above the eyebrows, dissection starts above the deep temporal fascia and then passes to superficial temporal fascia, where fat is present (about 1 cm above the zygomatic arch). It's important to preserve this fat to avoid muscle displacement. To put the two dissection areas in contact, make an incision in a superficial fascia, 15-20 mm up the zygomatic arch. Perform medial temporal muscle dissection in contact with the frontal bone and a large subperiosteal dissection in the orbit and cheekbone area. The zygomatic arch should be dissected in the anterior and posterior part. The zygomatic arch osteotomy leaves the masseter muscle inserted. Perform zygomatic arch displacement before and, dissect the masseter muscle deep fibers to arrive at the prolongation temporal muscle in the buccal fat pad. Subperiosteal dissection should be performed forward and obliquely up to ascending mandible ramus. Oblique section of coronoid apophysis, in higher position possible, without temporalis muscle shutdown (this move is used to take advantage of the entire muscle length). For temporal muscle release, make an incision of 5 mm 1 cm above the temporal crest in the anterior muscle portion to leave an aponeurosis portion inserted on the bone. Complete disconnection of the posterior muscle portion until temporal crest. Take care during inferior dissection of the temporal muscle at the spheno-temporal crest where we find the vascular nervous package.

Difference in the Monocoronal approach: avoids superficial undermining of the anterior part of the temporal muscle (see pictures); performs osteotomy of coronoid process with a nasolabial approach, avoiding Zygomat's osteotomy. Presents a damage risk for main vascular pedicles if you aren't practiced with the anatomy [14, 15, 16].

Figure 19. Lengthening temporalis myoplasty: the images show two different approaches, coronal and hemicoronal, and their differences in surgical terms.

Lower Approach Dissection

Face dissection is performed on the nasal fold starting from alar nose. Subcutaneous antero-posterior dissection is performed from the nasal fold toward the cheekbone to recreate the zygomatic major and minor muscles' path. You have to identify and prepare orbicular muscle and modiolus before suturing the temporal muscle with three points at these structures. These points will be placed in order to reproduce the three different types of smile. The subcutaneous dissection becomes deeper at the level of the buccal fat pad in contact with the maxilla-malar junction to join the temporal muscle, still attached to coronoid process before osteotomies. Using the subcutaneous path previously prepared, catch the coronal bone using an Ellis, and with linear and continuous traction the bone fragment is pulled down to reach the orbicular muscle. With dissection of the muscle tendon temporal from coronoid process with a scalpel, we obtain a 4 cm width tendon. We attach the temporal muscle at the three points previously prepared on the orbicular muscle with a U suture. The position of the temporal tendon on the orbicular muscle at the modiolus level, was defined based on smile types. The suture will be completed at the level of the orbicularis muscle with 5-10 non-absorbable points, with a light overcorrection. Taking the upper portion of the temporal muscle with two pliers, make an upward traction to test the position of the future smile [17, 18, 19].

Figure 20. This image shows in detail the different ways suture in function of the smile.

Figure 21. Anatomy of the modiolus, this is the convergence area of the smile's muscles zygomaticus major, risorius, buccinator and platysma.

Suturing and Closure

Suture temporal muscle on the aponeurosis, previously left attached at the bone, with 3-5 non-absorbable points. Perform osteosynthesis of the zygomatic arch. Place sutures at the level of the nose labial fold and on the coronal approach. Put in place two drainages: one in the frontal position, one under the zygomatic arch.

Figure 22. Exit of the facial nerve from the foramen stylomastoideum.

Anastomosis of Masseteric/Inferior Branch Facial Nerve (Physiologic Technique) (on youtube: www.youtube.com/watch?v=GdzYbSoneuo)

Classic Technique

Under General anesthesia and previous local anesthesia too, a facelift-type incision is performed beginning in the temporal region, passing hidden behind the tragus, continuing under the earlobe, and extending into the mastoid region. An anterior-inferior skin flap is elevated in order to access the parotid-masseter region. We identify the facial nerve's exit from the styloid foramen by the standard extra cranial antegrade technique (see Figure 22). The zygomatic arch is exposed and the posterior half of masseter muscle is carefully dissected off the bony arch [20, 21, 22, 23]. We identify the masseter nerve and dissect it into the muscle to secure adequate length. We continue the facial nerve dissection started earlier with identification, until its bifurcation in the principal upper and lower division. The lower division is cut off the main trunk and mobilized sufficiently to permit its anastomosis, without tension, to previously dissected masseteric nerve. This suture will be performed under the microscope with 4 points 10/0 nylon suture in position time 12, 3, 6, 9 [24, 25, 26].

Mini-Lifting Approach Technique

This technique is based on the "subzygomatic triangle" area (see earlier) [27, 28]. Anatomic landmarks of this area are the temporo mandibular joint, the zygomatic arch, the sigmoid notch, and the malar eminence. A modified mini-facelift-type incision is performed

with an extension into the temporal hair tuft. The vertical incision extends to the preauricular crease and stops just before the ear lobule. The musculocutaneous flap is prepared and the parotid fascia is exposed. Blunt dissection through the parotid-masseteric fascia is used to identify the buccal branch of the facial nerve. The facial nerve is safely retracted. Blunt dissection is carried out within the subzygomatic triangle into the substance of the masseter muscle. Once identified, the masseter nerve is traced inferiorly for approximately 2 to 3 cm until it arborized. It is divided and transposed on the buccal facial trunk and a tension free neurorrhaphy is performed (see Figure 23).

Figure 23. Masseteric anastomosis: in yellow, the facial nerve; in blue, the masseter nerve. A termino-terminal anastomosis will be effectuated between the two nerves.

Suturing and Closure

Suture planes with resorbable suture. Continue skin suture with prolene 4/0.

Ancillary Technique Eyebrow

Indication to Use

The choice of technique is dependent on patient's general conditions. In the case of coagulation disorders or treatment of small eyebrow asymmetry, the double needle technique is better because it is less invasive. If general conditions are good and the patient presents a large asymmetry or risk of sensibility to the suture, frontal lifting is the best option.

Frontal Lifting

(on youtube:www.youtube.com/watch?v=KT4XZMwbWbE)

Under general anesthesia, we can perform this technique easily and quickly. We can combine this to all other procedures described before. We also use local anesthesia to prepare our dissection zone.

An irregular incision of 4-6 cm is performed inside the temporal hairline; we respect the oblique cut line to preserve hair follicles. We identify the deep temporal fascia and with a smooth periosteal dissector we make our posterior dissection to the eyebrow tail, in the lateral cantal skin as well, and to the head of the eyebrow anteriorly.

Figure 24. Frontal Lifting. The images show the incision and limits of the area and method of dissection.

This is a not risky dissection if performed tight to the temporal deep fascia, because facial nerves run superficially in this. After total detachment of the area of interest, the temporal skin is elevated. The suture to stabilize the eyebrow will perform securing the points to deep fascia. 4-6 point non-absorbable sutures are sufficient to give the desired lifting effect.

The excess skin is cut following the irregular line and sutured with 4-0 Vicryl and stainless steel skin clips.

Do not use any drainage, but a compressive bandage is requested for 48 hours to avoid surgical sequel [29, 30, 31].

Static Suspension with Non-Absorbable Suture Double Needle

This is a very quick and easy procedure to perform. You can perform this technique almost without risks.

Perform local anesthesia at the needle insertion point, in the zone of entry and exit of the needle. Two double-needle sutures are necessary to lift the eyebrow, one at the level of the eyebrow's head and another at its tail. The smooth portion of the suture is 'the traction point'. Keeping 3-4 cm at the level of the head and 3-4 cm at the tail level is sufficient to obtain a very good result. This is a bidirectional convergent suture, so you can obtain 4-point traction with only two sutures [33, 34, 35].

Figure 25. Double needle suture.

Figure 26. Static suspension with double needle suture at the level of the head and tail of eyebrow. Insertion of the needle starting at point 1; at the level of point 2, turn the needle directly to point 3 in a horizontal line, then turn the needle in a vertical line directly to point 4 until exiting to the skin. The black arrows show the direction of needle during the three passages. The empty arrows show the direction of the traction of the suture. After the needle's passage from point 1 to point 4, cut the needle. It will simply make a symmetrical traction on two threads for the suspension of the area of interest. The threads possess some bidirectional spines able to engage and support the tissue without making suture to subcutaneous tissue or the fascia a necessity.

CONCLUSION

As shown in this chapter, the choice of technique has the goal of achieving good results with less invasive surgery.

Chapter 398

SETTING UP A MINIMALLY INVASIVE AORTIC VALVE SURGERY PROGRAM

Hunaid A. Vohra^{1,*} and Christopher P. Young²

¹Department of Cardiac Surgery, Bristol Heart Institute, Bristol, UK

²St. Thomas' Hospital, London, UK

ABSTRACT

Here we describe in detail the logical procedure and philosophical approach to establish a minimally invasive aortic valve replacement programme in the current era. The philosophical lessons learnt from the experiences are highlighted. It is hoped that this chapter will act as a template for newly established surgeons to embark onto a minimally invasive aortic valve surgery program. Although some technical fallacies are highlighted, the main aim is to focus on the non-surgical factors that could have a huge impact on the success of such an endeavour.

Keywords: valve, aortic, program, minimally invasive

INTRODUCTION

Clinical effectiveness and patient safety is paramount when introducing a new procedure or technique in the current National Health Service (NHS) climate. Here we describe in detail the logical procedure and philosophical approach to establish a minimally invasive aortic valve replacement program in the current era. A real example of a NHS Trust in the United Kingdom has been described in a step-wise manner. The outcomes of the new procedure established in this fashion are reported and the philosophical lessons learnt from the experiences are highlighted. It is hoped that this paper will act as a template for newly established surgeons to embark onto a minimally invasive aortic valve replacement (MIAVR) programme.

* Corresponding Author's Email: Hunaid.Vohra@UHBristol.nhs.uk.

ESTABLISHING THE NEED

MIAVR is now an established procedure. The first parasternal approach for MIAVR was reported by Cosgrove and Sabik [1] in 1996 following the minimally invasive revolution in general surgery in the late 1980's. Further evolution has resulted in the upper hemi-sternotomy (UHS) and the anterior right thoracotomy (ART) approaches to be currently the most popular ones. UHS provides a window through which the aortic root is freely accessible. Without additional risk to the patient, the surgeon applies slight modification to already established familiar techniques. This offers the patients the benefit of prompt recovery in appropriately selected patients and enhances patient choice and patient experience. Although suited for isolated AVR in patients of all ages, MIAVR is particularly applicable to the elderly, obese, recent smokers and those with impaired respiratory function. As compared to a conventional sternotomy, UHS leaves the sternum more stable and is particularly suitable for patients who may have a higher risk of sternal dehiscence but otherwise suitable for conventional AVR. Hence these are not patients who would be considered for trans-catheter aortic valve replacement (TAVR). Some studies have demonstrated reduction in hospital stay with MIAVR. With an increasingly elderly population in a tight fiscal climate, reducing the length of hospital stay after AVR, even by 1-2 days, could translate into better overall clinical outcomes and huge savings. Applying this argument would be a key selling point when trying to set up a MIAVR service in a cardiac surgical unit. A smaller scar, less pain and blood loss are other potential benefits. In centres where this procedure is well-established, the referral base has significantly increased as MIAVR is requested both by the patients as well as the cardiologists.

TRAINING

It is also important to establish any training needs, not only for the surgeon, but the whole team including anesthetists, perfusionists and the scrub team. Before the first cases are performed, local departmental teaching should be organised (lectures, evidence, videos, etc.) where all disciplines are invited. We used a combination of theoretical information as well as operative footage in order to familiarise the team with the procedure and its potential pitfalls. Visits to 'MIAVR centers' and attendance at courses targeted at new centres are strongly advised. From the surgical perspective, at least 2 surgeons are required with an interest in minimal access surgery. An experienced aortic valve surgeon teaming up with a newly appointed surgeon would be the ideal combination. Enthusiasm and wisdom are the 2 key elements that are required to set up such a programme. In our experience, a senior Consultant had performed hundreds of conventional AVRs and had visited a UK centre to observe MIAVR. On the other hand, a junior Consultant had performed >100 conventional AVRs but had spent time in fellowships, first learning minimally invasive surgery in another European center and then returning to another fellowship at St. Thomas' Hospital, UK focusing on MIAVR, TAVR and rapid deployment valves.

NEW PROCEDURE APPROVAL BY THE HOSPITAL

NIPAG Application

In most UK hospitals, all new procedures need prior approval from a committee, for example, 'New Interventions and Procedures Advisory Group (NIPAG).' It is crucial that the team endeavours to gain approval from such committees, if they exist in other countries, before embarking onto a MIAVR programme. This ensures patient safety, highlights clinical governance and maintains quality control. The NIPAG application requires description and indications of the proposed procedure, intended benefits, possible complications, summary of evidence base, estimated number of annual procedures to be performed, names of supporting colleagues, names of performing colleagues and letter of support from lead clinician.

Support from Colleagues

Ideally, the proposed procedure should be discussed with all Consultant surgical colleagues formally and their support sought, even if all of them would not be performing the new procedure. The names of the surgeons performing the operation in the 'setting-up' phase should be specified. Once this phase has passed and the final approval from NIPAG granted, other surgeons may also be able to embark onto the programme with appropriate in-house training.

Proctor

It should be considered compulsory to have a named proctor with considerable experience and reputation in the field to provide training and supervision in the first cases performed. The ideal proctor is one with whom at least one of the operating surgeons has worked or trained with before.

Patient Information Leaflet

NIPAG also requires that a patient information leaflet is devised in a language easily understood by patients where it is clearly stated that this is a new procedure to the trust but the surgeons involved are adequately trained and will be initially supervised to perform this. The leaflet informs the patient of the potential benefits and that this operation would not put the patients at higher risk of harm as compared to conventional surgery. Reassurance should also be provided that in case of a serious complication the incision will be made bigger to control the situation. The leaflet is intended to educate the patient with respect to the 'new technique' and provides them with an option they may wish to consider.

Audit

NIPAG also requires that individual patient audit and a summative audit is provided after the first 20 cases are performed. Any untoward serious event must be reported and copied to NIPAG. This provides the foundation for the final Trust approval. Regardless, once the procedure becomes well-established, 6-12 monthly audit with morbidity and mortality figures would be recommended best practice.

Cost

Although new additional costs can be involved, MIAVR by the UHS technique can generally be performed without the requirement for any special equipment. The Hospital Management should be reassured that extra funding would not be required for starting a MIAVR programme, at least in the initial phase, when UHS would be employed.

TAKE-OFF**Communicate**

Before the programme commences, every effort must be made to encourage open discussion in a relaxed environment, to exploit every opportunity to highlight concerns regarding equipment and training and to facilitate team-work and boost morale. This becomes paramount if previous experiences have not been positive. Frequent informal dialogues in corridors and coffee rooms as well as formal discussions at regular Consultant, Monthly Audit and other Clinical Governance meeting should not be under-estimated.

Patient Selection

In the initial period (first 20 cases), patient selection is the key. Avoid very elderly, grossly obese, current smokers and high-risk patients. Once the programme is 'up and running', it is these very patients who might benefit from MIAVR. At the outset, the skin incision can be made slightly longer as it is the mini-sternotomy and not the skin incision which provides clinical benefit. A flow chart of patient selection for MIAVR is provided (Figure 1).

Proctor Contract

As the proctor is likely to be working in another hospital, he will require an honorary contract to be able to visit the center where the new procedure is envisaged. To avoid last minute disappointment, ensure that this is organised beforehand. Although sounds tedious,

but this can be easily and quickly done by communication between the two Human Resources Departments, especially if they are within the same country.

Flow Chart for Patient Selection for mini-AVR

Key: AVR - aortic valve replacement, PIL - patient information leaflet, OPD - out-patient department, MDT - multi-disciplinary team.

Figure 1. Patient selection flow chart.

Team Briefing

Prior to the first case, the whole team must be extensively debriefed (with the proctor present) and ensure that all equipment required is available. It is important that all members of the team are encouraged to ask questions at this point to provide further opportunity to highlight issues and promote team involvement.

First 20 Cases

The first case in our programme was performed by the senior Consultant with the proctor as the first assistant and the junior Consultant as the second assistant. The second case was again performed by the senior Consultant with the junior Consultant as the first assistant and the proctor observing unscrubbed. During these cases, there were frequent technical points discussed which helped enormously. Thereafter, another 3 cases (unproctored) were performed by the 2 surgeons scrubbed together and then the rest of the first 20 cases were performed by one surgeon individually with the other surgeon on back-up within the hospital, if required. After the first 20 cases, the audit should be submitted to NIPAG and final approval sought. Initially, the cross-clamp time and total procedure is longer than conventional AVR but this reduces rapidly once the learning-curve is overcome.

Examples of Technical Difficulties

Although not the subject of this chapter, nevertheless below are some examples of technical difficulties that were experienced in the initial phase of the program with a brief explanation of how they were solved.

Difficult Access

By increasing the length of the skin incision and/or changing from a J to a T hemi-sternotomy or sternotomy into the 5th intercostal space instead of the 3rd or 4th space.

Right Atrial Venous Pipe 'in the Way'

Use a flat venous cannula and pass it under the retractor before connecting to cardiopulmonary bypass circuit.

Blocked Drain

Using 2 drains of two sizes smaller instead of one big drain.

Difficulty in Placing Ventricular Pacing Wires

Insert while the heart is still before removing the cross-clamp.

Key Lessons Learnt

- Work together with an experienced surgeon
- Proctor essential
- Always have back up
- Do not be afraid to convert
- It is not as difficult as it sounds

CONCLUSION

The universal adoption of MIAVR in contemporary cardiac surgery seems inevitable in the foreseeable future. It is a safe and logical option from the data provided so far from studies and registries. An open-minded and enthusiastic team will undoubtedly be able to facilitate the introduction of this 'new service.' The 'starting-up' period can be daunting for a newly appointed surgeon. However, a sensible approach will provide safe and sustainable outcomes.

Chapter 399

CT IMAGING AND ECHOCARDIOGRAPHY FOR MINIMALLY INVASIVE AORTIC VALVE SURGERY

Gabriel Loor¹, MD and Eric E. Roselli^{2,*}, MD

¹University of Minnesota, Department of Surgery, Division of Cardiothoracic Surgery,
Minneapolis, MN, US

²Cleveland Clinic, Department of Thoracic and Cardiovascular Surgery
and Center for Minimally Invasive Cardiothoracic Surgery, Heart and Vascular Institute,
Cleveland, OH, US

ABSTRACT

Minimally invasive aortic valve replacement (MIAVR) compared with conventional AVR offers the potential for less pain, blood transfusions and resource utilization. Yet none of these benefits are realized if an adverse event occurs due to compromised exposure. Preoperative imaging levels the playing field; MIAVR becomes as feasible as a conventional AVR when the right exposure is chosen for the right patient. Here we review the use of preoperative imaging technology to select the appropriate candidates for MIAVR. We review our operative technique and the role of high resolution 3D reconstruction and echocardiography in the choice of surgical exposure and intraoperative management.

Keywords: minimally invasive, aortic valve replacement, computed tomography, echocardiography

INTRODUCTION

Surgical aortic valve replacement (AVR) including excision of the native valve and hand-sewn fixation remains the gold standard treatment for aortic valve disease with the longest data on freedom from reoperation and survival [1, 2]. Minimally invasive aortic valve

* Corresponding Author's Email: roselle@ccf.org.

replacement (MIAVR) has come a long way from the days of it being a highly specialised procedure offered only by a few surgeons. With appropriate use of preoperative imaging, careful patient selection, and experience, mortality rates for MIAVR can remain below 1% even with concomitant procedures [3]. It has now become the method of choice for isolated AVR at many centres. There is little tolerance in the current era for complications associated with exposure. The current chapter highlights our surgical approach to MIAVR and the role of imaging in determining patient selection and operative exposure.

OPERATIVE TECHNIQUE

Before we discuss the role of imaging, we will briefly review our technique for minimally invasive exposure which has evolved slightly from the original descriptions in the mid 90's by Drs. Cosgrove and Sabik [4]. The most commonly used exposure remains the mini-upper hemisternotomy (UHS). Typically a 6-10 cm skin incision is made starting 2 finger breaths above the angle of Louise (Figure 1A) [5]. A modest subcutaneous flap is raised at the upper and lower borders of the incision to allow access to the sternal notch and 4th intercostal space (ICS), respectively. Cosmesis is an important feature of this technique, hence the value of a smaller incision. On the other hand, the sternotomy portion remains the same no matter how big the skin incision and we believe the real benefit from a minimally invasive incision comes from the maintenance of chest wall respiratory physiology. Making the skin incision 8 cm or bigger may allow better visualization of the aorta for cannulation which is important for safety in the beginning of the operator's experience.

The 4th ICS is carefully dissected out so that the right lateral edge of the sternum is visible and accessible. Electrocautery is used to score a line in the sternum from the sternal notch, down the midline to just above the 4th ICS. This mark is slanted down towards the right lateral edge of the 4th ICS in a so called "J" configuration. The lungs are disconnected from the ventilator and the saw is engaged in the sternal notch. The sternum is divided along the outlined mark and slanted into the 4th ICS (Figure 1B). We prefer the J incision made with one saw over the so called "reverse L" configuration made with two saw blades at a right angle because the bone comes together more regularly with the former. We also prefer either of the former sternotomies to a full "inverted T" incision where the partial sternotomy includes a transverse sternotomy because the integrity of the chest wall is better preserved with the lesser incisions. Care is taken to avoid injuring the skin and the right internal thoracic artery during these manoeuvres.

Once the sternotomy is complete, hemostasis is obtained above and below the sternal edge and the 4th ICS is carefully inspected to ensure that the mammary artery and vein are not injured. If they are, they should be clipped and divided to prevent bleeding. Now a mini-sternal retractor is inserted and gradually opened. Care is taken to avoid excessive traction injury on the skin. The thymus is divided down the midline and the pericardium is entered. Hemostasis needs to be excellent since any bleeding will be magnified through minimally invasive exposure. The pericardium is opened inferiorly as far as possible and superiorly towards the innominate vein. Three stay sutures are placed on either side of the pericardium. Anesthesia is advised that the pressure may drop with pericardial elevation. Intravenous fluids and pressors are used as needed. The lungs are disconnected from the ventilator, the retractor

is removed, and the stay sutures are elevated and tightly secured to the sterile towels or sutured to the skin edge. The retractor is then re-inserted within the pericardium and the exposure is complete (Figure 1C).

For the mini anterior right thoracotomy (ART) approach, we make a 6 cm incision over the right 2nd ICS. The third intercostal rib head is transected close to its attachment to the sternum to improve exposure taking care to avoid periosteal or perichondral injury. A soft tissue retractor is inserted into the wound, and the mini-sternal retractor is inserted and gradually opened. The pericardium is entered and retracted with stay sutures to pull the aorta into the operative field. Certain adjuncts such as lighted retractors, auto suture devices like the Cor-knot (LSI solutions, Victor, NY), or the use of newer sutureless bioprosthetic valves can facilitate minimally invasive approaches. The rib is usually reattached to the sternum with a plate.

Peripheral cannulation is always an option but we prefer central cannulation due to the atherosclerotic burden that is common in these patients with calcific aortic valve disease and the associated risk of stroke. Retrograde cardioplegia is our preferred approach for protecting the heart during most conventional cardiac operations, but it is not completely reliable during MIAVR. The consequences of inadequate cardioplegia during an AVR can be devastating. Thus, we typically rely on antegrade induction with modified Buckberg cardioplegia followed by intermittent doses with direct infusion into the right and left coronary ostia. More recently, we have used single dose Del Nido cardioplegia to ensure an uninterrupted 1-1.5 hour cardiac arrest interval. A recent study by Mick and colleagues showed decreased operating times, no hospital deaths, similar troponin T levels and no change in left ventricular ejection fraction with Del Nido solution compared to modified Buckberg [6].

Figure 1. Operative technique. A). Skin incision B). Sternotomy ("J") C). Final exposure (reprinted with permission Malaisrie et al. *JTCVS* 2014 [30]).

The AVR proceeds as usual. Any aortotomy of choice can be used and root enlargements are sometimes required. Stay sutures at the commissures may be helpful for elevating the annulus in the operative field. Complete valve excision and debridement is performed and we double check that all calcium debris has been irrigated and suctioned. Meticulous technique is required to ensure proper suture placement and symmetry. We do not typically use a superior pulmonary vein vent, so exposure to the right superior pulmonary vein is not mandatory but feasible. We use a drop in flexible suction catheter in the left ventricular outflow tract instead. With experience operating times through a mini incision approach those through a conventional incision.

BENEFITS OF MIAVR

There is a greater time and financial investment involved with preoperative imaging so there has to be a gain to MIAVR that justifies this. Here we highlight some of the data comparing outcomes for MIAVR compared with conventional AVR.

Tabata and colleagues reviewed 1000 minimally invasive aortic valve procedures and showed an operative mortality of 1.9% with 10 year survival of 88% [7]. Incidence of deep sternal wound infection, pneumonia and reoperation for bleeding were 0.5%, 1.3%, and 2.4%, respectively. The Cleveland Clinic experience recently showed an operative mortality below 1% even with adjunctive procedures [1]. Bakir and colleagues noted decreased blood use and decreased hospital stay with MIAVR compared with conventional AVR [8]. A recent review of the Brigham and Women's Hospital experience showed decreased blood use, ICU and hospital stays [9]. Ghanta and colleagues reviewed 289 propensity matched patients and showed decreased blood use, ventilator time, hospital stay and a cost reduction of approximately \$1,891 with MIAVR [10]. Gilmanov and colleagues' analysis of 182 propensity matched pairs demonstrated a lower incidence of atrial fibrillation and blood use with MIAVR compared with conventional AVR [11]. Similar benefits have been reported by several additional investigators [12-15].

Not all studies have found a resounding benefit for MIAVR. Phan and colleagues utilized a Bayesian meta-analysis of 6 databases. They found that clamp duration and bypass times were longer with the ART approach but equivalent with the UHS approach [16]. Other short-term outcomes were equivalent. A larger meta-analysis by Phan and colleagues showed that overall quality of evidence for trials comparing MIAVR and conventional AVR is poor [17]. Yet they concluded that MIAVR was associated with similar mortality, and trends towards reduced ICU stay (by about half a day), hospitalization (by about a day), renal failure, transfusions, and pain. Stamou and colleagues reviewed 500 AVRs and showed no difference in blood transfusions after controlling for patient risk factors [18]. Detter and colleagues compared 70 MIAVR and conventional AVRs and showed no difference in any of 8 quality of life categories, in patient satisfaction, or in judgment of the cosmetic aspect. The lack of superiority found in these studies should caution the surgeon to reduce morbidity as much as possible by optimizing preoperative planning. It is hard to justify a complication related to exposure.

An appreciation for the use of preoperative imaging should allow for further development of even less invasive minimal access approaches. This will become increasingly apparent as

other AVR technologies evolve. A collapsible sutureless aortic prosthesis like the Perceval valve (LivaNova, Milano, Italy) can be delivered into the mediastinum through a port sized incision [19-22]. Miceli and colleagues showed that MIAVR compared favorably with transcatheter AVR (TAVR) for high risk candidates [23]. They noted zero strokes for the sutureless valve compared with 5.4% for TAVR, zero deaths compared with 8% for TAVR, no paravalvular leaks compared with 27% for TAVR, and a 91% 2-year survival compared with 66% for TAVR. In addition, Gosev and colleagues recently showed that patients who require a redo AVR after a MIAVR do better than those who require a redo AVR following a standard sternotomy [24]. They noted shorter operating times, shorter vent times, and better long-term survival (100% 5-year survival for prior MIAVR compared with 85% 5-year survival for prior standard sternotomy). There are several potential benefits to minimally invasive exposure, but none of these are realized if the exposure is poor or circulatory support techniques are compromised.

Potential Pitfalls Related to Exposure

Conversions to standard sternotomy are required 1-8% of the time even in experienced hands [25, 26]. While conversions are necessary and warranted in the setting of poor exposure, it was associated with as high as 33% mortality in one series [27]. The most common reason for conversion involves issues with inadequate exposure although ventricular arrhythmias, myocardial dysfunction and bleeding are other reasons.

The aortic cannulation site may be prohibitively far from reach or calcified. The atrial cannulation site may also be far from reach. Typically cannulation issues do not preclude a MIAVR as there are several alternative cannulation strategies, but it is ideal to predict these scenarios ahead of time. An aortic annulus that is far from the operator's field can compromise complete and safe calcium debridement, suture placement and seating of the valve. Paravalvular leaks and coronary occlusion are complications that can occur as a consequence of poor exposure. One series found that up to 6% of MIAVR required revision or alteration of the operation in the same operative setting.

Preoperative Imaging with Computed Tomography

Achieving safe exposure is directed at two elements of the operation: (1) visualisation and access to the distal ascending aorta and right atrium for central cannulation and (2) visualization and access to the aortic annulus after cross clamping and arrest. Since 2006 we have increasingly adopted computed tomography (CT) to predict the most optimal exposure for an individual patient who is otherwise deemed a candidate for minimally invasive valve surgery. We have noticed that patient anatomy is variable; an exposure that works for one individual may not work for another. Preoperative planning has reduced our rate of unanticipated conversions to full sternotomy. The correct exposure allows for MIAVR to proceed with little difficulty or risk as compared to conventional AVR. This is true for patients at all levels of risk and variations in body habitus including the morbidly obese and those with chest wall deformities like pectus excavatum.

As mentioned above, there are several options for exposure including the following: (1) conventional upper hemisternotomy (UHS; J sternotomy) into the right 4th ICS, (2) extended upper hemisternotomy into the right 5th ICS, (3) lower hemisternotomy (inverted J) into the right 2nd or 3rd ICS, anterior right thoracotomy (ART) into the 2nd ICS, (4) mini-skin (11 cm) full sternotomy, and (5) conventional sternotomy. Ongoing investigations are focused on developing a robotically-assisted port approach. The main point is to select an exposure that is conducive to a safe operation while harnessing the benefits of a minimally invasive approach.

Ammar and colleagues first described the use of non-contrast CT for surgical planning of MIAVR in 1998 [28]. They identified intraoperative variations in patient anatomy and aortic annular location easily predicted by the preoperative CT scans. They tailored their incisions to the patients' anatomy and no patient required an extension or deviation from the anticipated exposure. Others have since advocated for the use of preoperative CT as standard of care for operative planning in MIAVR [29-33].

The advent of off-line three dimensional CT processing has simplified our ability to plan a cardiac operation. The bone removal function and soft tissue slab techniques allow the surgeon to fade from the skin level to the aortic annulus on any given scan (Figure 2A-C). For 3D reconstructions, the resolution of the aorta and its surrounding structures are enhanced with the use of IV contrast. Most AVR patients will require a contrast coronary angiogram prior to surgery which should be taken into account when scheduling the CT scan to avoid excessive dye boluses. Alternatively, cardiac MRI, while more expensive, can be used to plan surgical incisions and provide substantial granular detail.

Figure 2. Advanced off line 3D reconstructions allow gradual removal of bone and soft tissue (A→C). This provides a road map from skin to annulus to guide the operative approach.

Figure 3. 3D high resolution reconstructions depict variations in human anatomy. A). The aortic annulus is in the expected position, midline, 4th ICS. A standard mini-AVR into the 4th ICS provides optimal exposure B). The annulus is slightly lower than expected. Bone fragmentation suggests that extension of the sternotomy to the 5th ICS would provide optimal exposure. C). The annulus is extremely low and near the xiphoid. Bone fragmentation suggests that an inverted lower hemisternotomy extended into the right 2nd or 3rd ICS would provide adequate exposure. (Reprinted with permission Loo G and Roselli E, *JACC: Imaging* 2013 [32]).

For illustration, we will review 4 cases depicting anatomical variations detected with preoperative CT [32]. We utilize 3D reconstructed contrast-enhanced multi-detector computed tomography (MDCT). All cases employ MDCT technology using an iCT256-slice scanner (Phillips, Andover, Massachusetts) to acquire prospectively triggered axial images. Low osmolar iodinated contrast optimizes visualization of the vasculature in relation to the bony thorax. Multi-planar reconstruction, maximum intensity projections, volume rendered reconstructions and advanced 3D off-line post-processing is performed on a dedicated stand-alone workstation (AcquariusNET, TeraRecon, Inc, San Mateo, California) that is available on each surgeon's desktop, in the outpatient clinic, and in each operating room.

In the first scenario (Figure 3A) CT showed an aortic annulus slightly above the 4th ICS and at the middle of the sternum. This is ideal for the standard UHS. The exposure to the annulus and cannulating areas was no different than a conventional AVR. Note that the aorta did sway towards the right at the level of the 2nd ICS. Thus, ART could have been considered.

Figure 4. The right lateral thoracotomy exposure A-C). 3D reconstruction and virtual planning suggests the right thoracotomy approach would be ideal for this patient with the aorta deviated to the right (Reprinted with permission Loor G and Roselli E, *JACC* 2013 [32]). D). A vertical line from the right sternal border to the aorta shows >50% of the aorta to the right of this mark. This suggests optimal exposure via right anterior thoracotomy. (Reprinted with permission Glauber et al. *JTCVS* 2011 [34]).

The next example (Figure 3B) shows an aortic annulus closer to the 5th ICS. The choices include a conventional median sternotomy, a mini-incision (11 cm) full sternotomy, or a MIAVR through the 5th ICS. The latter extends the sternotomy slightly more than the 4th ICS standard UHS but spares the complete sternotomy and allows for a smaller skin incision (8cm). While this is not common, the 5th ICS extension is much better than struggling through the 4th ICS. The valve anatomy was very comfortable to see and dissect. The third example (Figure 3C) is a patient with an annulus nearly at the level of the xiphoid due to an aneurysmal ascending aorta. In this case an inverted sternotomy with extension into the right 3rd ICS was used. The exposure was excellent.

The final example shows a patient with the aorta and annulus shifted up and towards the right 3rd rib head (Figure 4A-C). This is ideal for an ART approach. We had easy access to the ascending aorta for clamping and the delivery of antegrade cardioplegia. Additional imaging through the chest, abdomen and pelvis can be included to assess the feasibility for femoral bypass if central access cannot be achieved safely.

When using preoperative imaging it is helpful to have certain standard measurements to make your decisions about exposure. For instance, if the aortic annulus is above the 4th ICS and in midline or to the left then a standard UHS is indicated, if the annulus is to the right of midline then a right lateral thoracotomy can be safely considered, if the annulus is lower than

the 5th ICS then an extended right upper hemisternotomy will facilitate exposure, and if the ascending aorta is below the 2nd ICS then an inverted hemisternotomy will work. There are no published standards to guide these decisions and they serve as general guidelines. As one gains experience using CT to guide the decision-making process and with the intraoperative manipulations available to assist exposure, a better understanding will be gained about tailoring the various incision options to each patient. Manipulation of the 3D images by removing soft tissue and bone allows you to position the patient as one would for surgery and mimic the operative exposure. In these cases it becomes evident whether a specific exposure will work.

Even without reconstructions, rough measurements based on trial and error can guide the surgeon towards the correct exposure. For example, Glauber and colleagues suggest that if more than half of the ascending aorta is to the right of a vertical line drawn from the right sternal border to the ascending aorta on an axial cut (Figure 4D) then the ART approach is reasonable [34].

There are other benefits gained from having a preoperative CT scan for operative planning. It can show the extent of calcium or extension of such into the outflow tract, coronary ostial location in relation to the annulus, and annular size [35]. Understanding the size of the annulus may assist with device choice such as whether a root enlargement may be anticipated. CT can guide cardiopulmonary bypass strategies by clarifying plaque burden and distance to the cannulation sites. For redo operations, the CT is indispensable in clarifying the proximity of vital structures to the posterior sternum [36]. Thus, preoperative planning with 3D reconstructions of a contrast chest CT reveals potential pitfalls prior to the operation.

ECHOCARDIOGRAPHY AND MIAVR

Echocardiography also plays an important role in the preoperative planning and intraoperative management for MIAVR. Transthoracic echocardiography (TTE) allows confirmation of the presence and severity of valvular disease. It provides details related to the valvular and subvalvular apparatus. It reveals significant subvalvular gradients and hypertrophy which may alter the operative approach. It demonstrates the extent of aortic insufficiency that may have implications for myocardial protection during MIAVR. For instance, Del Nido cardioplegia solution delivered via a cannula in the proximal ascending in a patient with moderate or more aortic insufficiency may be interrupted after the heart becomes bradycardic enough, and then followed by direct delivery into the coronary ostia.

If retrograde cardioplegia into the coronary sinus is the preferred method of cardiac protection, trans-oesophageal echocardiography (TOE) has been helpful for retrograde cannula placement and confirmation of positioning into the coronary sinus. Infusion of air through the sinus port and use of cannulae with radio-opaque tips can also assist with TOE-guided positioning. Demirsoy and colleagues reported a success rate of 85% with TOE-guided retrograde cardioplegia cannula placement [37].

Echocardiography can clarify the details of preoperative myocardial function. A patient with a very low ejection fraction may be best approached through a conventional sternotomy depending on the details of the patient's disease and the surgeon's experience. Cross-clamp and bypass times tend to be longer with MIAVR and the quality of cardiac protection may not

be as reliable as when the entire heart is exposed. Low EF patients typically do not tolerate increased operative times or deviations in myocardial protection.

It has long been known that intra-operative echocardiography is useful for evaluating post bypass cardiac function and de-airing techniques during MIAVR, and was recently demonstrated to be the case in a study by Secknus and colleagues [38]. Echocardiography also revealed a problem with the valve requiring additional intervention to correct it in 6% of cases. Epicardial echocardiography can influence the location of aortic cannulation by revealing aortic plaque [39]. Thus, the preoperative and intra-operative echocardiography is helpful in documenting valve pathology, cardiac function, retrograde coronary sinus catheter placement, safe cannulation and de-airing. Echocardiography has limited role in planning the specific surgical incision site for MIAVR.

MIAVR AND BEYOND

Preoperative imaging also clarifies the potential for performing adjunctive procedures safely. Repair of ascending aortic aneurysm, for instance, is feasible through a minimally invasive exposure if preoperative CT scanning suggests that the aorta and valve are within the operative field of view (<http://www.ctsnet.org/article/mini-sternotomy-hemiarch-and-bicuspid-aortic-valve-bav-repair>) [40]. Operations requiring circulatory arrest are feasible through minimally invasive approaches with no compromise in safety by using preoperative CT to plan the approach. Re-operative AVR can also be carried out through UHS. The imaging should support a location of the annulus near or above the fourth ICS. Other features of the CT will be relevant for a redo-sternotomy such as the location of the innominate vein and other vital structures [41, 42]. Even redo-sternotomy on patients with a prior heart transplant for MIAVR has been described [43]. In an early series of 54 patients, Svensson and colleagues performed re-operations in 33%, composite valve grafts in 28%, and elephant trunk type procedures in 6% of patients. The survival rate was 96%, stroke 3.7%, mean circulatory arrest time was 20 min, and mean units of blood transfused were 1.3 [44].

Even concomitant aortic valve and mitral valve procedures can be performed in patients with reasonable anatomy. The UHS approach to double valve disease has been used successfully in Cleveland for over twenty years. Additionally, Lamelas published his experience with the “Miami Method” for performing concomitant aortic valve and mitral valve surgery via ART [45]. Preoperative imaging is used to clarify patients who are suitable for this approach. Interventions on the leaflets for moderate mitral regurgitation such as an Alfieri stitch are feasible if the exposure to the annulus and subannular apparatus are good [46]. Patients with severe mitral annular calcification or leaflet calcification should be excluded from this approach.

A variety of other adjunctive procedures have been described through the MIAVR exposure. Minimally invasive resections of fibroelastomas [47], root replacement and repairs [7], and a modified maze procedure can be safely performed if the exposure is adequate [8]. For these types of multi-component procedures, the anatomical exposure needs to be adequate and the means for myocardial protection need to be suitable. If there is any concern about protecting the heart during a longer operation, it is preferable to use a conventional sternotomy.

CONCLUSION

In conclusion, MIAVR may offer an advantage over conventional AVR in terms of decreased blood transfusions, length of hospital stay, ventilator time, recovery time and pain. These benefits are most pronounced in small series performed by very experienced surgeons. With conventional sternotomy as a competitive alternative, there is no room for compromise in the exposure. Current technology allows for readily available processing of preoperative CT imaging providing exquisite three-dimensional detail that should be used to decide if a patient is a candidate for MIAVR and how best to perform it. In addition to the details of valve morphology and pathology, echocardiography provides adjunctive information to guide cardioplegia and cannulation strategies. Preoperative imaging is mandatory to provide the safest application of minimally invasive techniques for patients undergoing MIAVR.

Chapter 400

ANAESTHESIA AND FAST-TRACKING IN MINIMALLY INVASIVE AORTIC VALVE SURGERY

Ben Gibbison*

Department of Cardiac Anaesthesia, Bristol Heart Institute/University of Bristol,
Bristol, UK

ABSTRACT

The main drive behind minimally invasive surgery is to reduce tissue damage. This is likely to translate into a smaller inflammatory response and faster recovery. Primarily, this aims to improve patient experience - meaning that patients have less pain, feel better and can return to their normal life sooner. However, this also aligns with incentives for healthcare providers to reduce hospital stays and improve efficiency. Inherent within the process for minimally invasive surgery should be a move towards improving recovery as measured by reduced intensive care and hospital stays. This chapter discusses anaesthesia for minimally invasive aortic valve surgery and measures to enhance fast-tracking post-surgery.

Keywords: anaesthesia, fast-tracking, minimally invasive, aortic, valve

INTRODUCTION

Lesser tissue destruction, change to respiratory mechanics and ultimately inflammatory activation, the fewer the post-operative problems. This is evidenced by trans-femoral transcatheter aortic valve implantation patients who, without the inflammatory response of bypass and sternotomy, are routinely discharged on the second post-operative day.

Traditionally, high dose opiates were given to cardiac surgical patients to abolish the neuro-hormonal responses to surgical insult. The trade-off of this approach is that patients need to be ventilated overnight in an intensive care unit. During the 1990s, fast-track cardiac

* Corresponding Author's Email: Ben.Gibbison@UHBristol.nhs.uk.

surgery emerged as a way to address increasing demand with limited resources. The drive to faster extubation means that in some cardiac surgical units, patients are now extubated “on table” at the end of the case and post-operative care provided in a dedicated post-anaesthetic care unit outside the main intensive care unit [1].

ANAESTHESIA FOR MINIMALLY INVASIVE AORTIC VALVE SURGERY

Patient Selection

Patient selection is critical to success in moving patients rapidly through the peri-operative care pathway. In theory, all elective patients should be considered as eligible for a fast-track programme - high risk patients may benefit from optimal preparation, reduced stays in the ICU, and increased mobilisation, although re-admission to the ICU is associated with a poor outcome. Predictors of failure in fast-track surgery are shown below and these criteria should be applied rigorously. i.e., if a patient meets any of these criteria at any stage, they should be removed from the fast-track pathway.

- Severely impaired LV function (<30%) [5]
- Long operative time (>4hrs 30min) [6]
- Long cardiopulmonary bypass time (>2hrs) [6]
- Impaired renal function (GFR < 65) [7]
- Non-elective surgery [5]
- Pre-operative intra-aortic balloon pump [5]
- ‘Redo’ surgery

It should be noted that when considering impaired renal function, it is the Glomerular filtration rate (GFR) that is the important value, not just the creatinine. Wide variance in GFR can be seen between individuals for the same serum creatinine level due to differences in sex, race, muscularity and other inherited and acquired differences [7].

Pre-Operative Assessment

Pre-operative assessment for minimally invasive aortic valve replacement (MIAVR) should be the same as any other cardiac surgical operation. That is that the severity and symptoms of the lesion should be established, as well as its consequences of the rest of the heart. The presence and severity of all co-morbidities must also be known.

When assessing patients for MIAVR, several pre-existing health conditions warrant further investigation:

- Cerebrovascular and peripheral vascular disease: Peripheral vascular disease is associated with an increased risk of stroke or systemic embolization with retrograde arterial perfusion. A CT of the chest and abdomen will delineate the anatomy of the vascular tree and a contrast angiogram will show potentially hazardous plaques

within the lumen. Knowledge of the size and tortuosity of the ilio-femoral vessels helps in correct cannula size selection.

- Previous cardiac surgery, lung conditions and chest wall deformity/irradiation: Chest wall deformity, irradiation and pre-existing cardiac surgery are all associated with adhesions and previous coronary surgery may mean that grafts cross the operative field. These can all be characterised by means of a CT chest. Airway assessment and pulmonary function tests to assess suitability for one lung ventilation should be assessed in those undergoing surgery via a thoracotomy approach.
- Co-existent coronary artery disease: If possible, evaluation of this should be carried out before CT angiography of the arterial tree due to the risk of iatrogenic dissection of the iliac artery during cardiac catheterisation. This could be catastrophic if unrecognised when the iliac vessels are cannulated at the time of MIAVR. A single, anterior graft can be carried out the time of MIAVR, although more usually treatment of coronary artery disease is by percutaneous stents.
- Trans-oesophageal echocardiography (TOE): is essential for safe conduct of minimally invasive surgery. Therefore, contra-indication to TOE should also be assessed. These include oesophageal carcinoma, stricture, varices or prior oesophagectomy.

Preoperative Preparations

Numerous methods have been attempted to help patients adequately prepare for cardiac surgery and ensure patients are in optimal condition prior to surgery. However, few of them have any real evidence-base to recommend them. Pre-operative physiotherapy [8] and respiratory exercises [9] have been shown to improve rates of post-operative pulmonary complications (atelectasis and pneumonia) after elective cardiac surgery. Pre-operative carbohydrate drinks close to surgery also have shown benefits in terms of reduced stays, but the Cochrane meta-analysis cautioned against the high risk of bias in these studies [10], although the risk of harm is low.

Perioperative Anaesthetic Considerations

Anaesthetic considerations for MIAVR should be as for any other cardiac surgical procedure. It should be remembered that conduct in the operating theatre affects post-operative care. Sedative pre-medication should be avoided and prophylactic antibiotics should be administered prior to urinary catheterisation. Large bore venous access and arterial monitoring should be established prior to induction of anaesthesia. To facilitate rapid extubation and recovery, moderate doses of short acting opiates, hypnotics and muscle relaxants are used. Despite multiple attempts comparing volatile with intravenous anaesthesia and different types and doses of opiates - no one type of anaesthesia has been shown to be beneficial in terms of meaningful clinical outcomes [11, 12]. Studies of remifentanyl, an ultra-short acting opiate, which does not accumulate, have shown reduced mechanical ventilation and hospital stay times without changes in mortality, although virtually all of these studies

were carried out in coronary artery surgery [13]. If using remifentanyl, care must be taken to give post-operative opioids 30 minutes prior to waking due to its short half-life. There is some evidence that remifentanyl has such profound effects on opioid receptors, that increased doses of post-operative analgesics are needed to overcome 'rebound' hyperalgesia [14].

A multi-lumen central venous catheter is placed and in some centres, a 9Fr pulmonary artery vent is inserted at the same site to minimise the number of cannulae arising from the incision (this is essential in the thoracotomy approach). Because of limited access to the heart for internal defibrillation during surgery, external pads should be both placed and connected to the defibrillator prior to the start of surgery. Careful attention to temperature maintenance is required after weaning from cardio-pulmonary bypass (CPB) to prevent falls in temperature. Heated mattresses, heated blankets, fluid warmers and head covering should be should all be employed. These methods should mean that complete rewarming is complete in most patients by the time of leaving the operating theatre. Similarly, conducting normothermic, or at least only mild hypothermic bypass is essential to maintain the post-CPB temperature.

Postoperative Considerations

Post-operative pain usually peaks within the first 48 hours after surgery, but usually declines from the second and third post-operative day - both from upper hemi-sternotomy and anterior right thoracotomy (ART). Limited rib retraction at ART and early drain removal shorten the period of peak pain. Patients under 60 years old have higher pain scores and so steps should be taken to pre-empt this [15, 16].

Evidence to support any one type of analgesia after cardiac valve surgery is missing. In principle, central neuraxial analgesia should be ideal for all surgical approaches to the heart. However, concerns still exist around bleeding in anti-coagulated patients near the spinal cord. A Cochrane review of thoracic epidurals in cardiac surgery showed no difference in terms of mortality, stroke or cardiovascular outcomes, but did show improved pulmonary outcomes and lower rates of dysrhythmias. The authors still counselled that these results should still be interpreted with caution and that there was still insufficient evidence to recommend this form of analgesia [17].

Opiates form the mainstay of analgesia, but regional adjuncts such as intercostal nerve blocks and paravertebral infusions can be useful for the ART approach and direct delivery of local anaesthetic to the wound using reservoir devices has also been used. Judicious use of non-steroidal anti-inflammatory drugs is also useful after the second post-operative day and ensuring that the renal function has returned to normal.

To assist with mobilisation, all intravenous catheters should be removed on the morning of the second post-operative day, along with the urinary catheter if the renal function is normal or returning to normal. Mobilisation assists with bowel habit, but prophylactic laxatives should be prescribed for all patients.

Trans-Oesophageal Echocardiography

Aortic valve replacement is a class II indication for TOE. However, as the surgeon's view of the heart decreases, reliance on the perioperative TOE increases. Thus, TOE is essential for minimally invasive aortic valve surgery. A complete perioperative TOE examination [18] should be completed in every case, but the key roles of TOE in minimally invasive aortic valve surgery are:

- Pre CPB
 - Confirmation of diagnosis
 - Ensure competence of the aortic valve for ante-grade cardioplegia delivery
 - Assessment of left and right ventricular function
 - Exclusion of an intra-cardiac shunt
 - Exclusion of aortic pathology
 - Mobile plaques
 - Aneurysmal disease
 - Dissection/intramural haematoma
 - Penetrative ulceration
- Peri CPB
 - Correct placement of the percutaneous venous cannula in the right atrium/vena cava
 - Exclusion of large Eustachian/Thebesian valves
 - Exclusion of prominent and obstructive Chiari network
 - Correct placement of the retrograde cardioplegia cannula in the coronary sinus
 - Exclusion of persistent left sided-SVC
 - Adequacy of de-airing
- Post CPB
 - Assessment of valve repair/replacement
 - Assessment of non-valvular complications
 - Exclusion of concealed bleeding
 - Pericardial
 - Pleural
 - Retroperitoneal

Placement of the Venous Drainage Catheter

Optimal surgical conditions are achieved by maintaining a still, flaccid, decompressed heart. Reducing venous return to the right side of the heart is accomplished by the venous CPB cannula. To reduce the risk of this large cannula when it is placed percutaneously, both the wire and then the cannula must be seen in right atrium. This is best visualised in the mid-oesophageal bicaval view at 90° with the probe turned to the right.

Placement of the Coronary Sinus Catheter

The coronary sinus catheter enables delivery of retrograde cardioplegia. The risks of misplacement are failure of delivery of cardioplegia and coronary sinus perforation. The

catheter can either be placed through the mini-sternotomy or percutaneously via a 9Fr sheath placed in the right internal jugular vein. A modified mid-oesophageal bicaval view (at 110-130°) is the optimal view for percutaneous catheter placement, as the whole catheter can be visualised at all times. In this view, the coronary sinus is seen in the centre of the view - appearing just below the left atrium. The catheter is placed in the sinus and confirmed by pressure monitoring. It is advanced as distally as possible to maintain stability. The balloon should then be inflated under direct vision. To ensure correct positioning - a ventricularised pressure trace should be seen and on injecting agitated saline, no bubbles should escape via the coronary sinus ostium. These two conditions must be met, even if the catheter looks adequately placed on echocardiography. New onset pericardial effusion during catheter manipulation should be treated as coronary sinus perforation until proven otherwise.

Placement of the Pulmonary Artery Vent

The pulmonary artery vent can be used as part of a complete venous drainage strategy and particularly if there is only one venous cannula in the right atrium. For optimal position, this should be placed exactly at the bifurcation of the main pulmonary artery (MPA) into its left and right branches. The catheter can be followed through the right ventricle and into the main pulmonary artery by viewing the right ventricular inflow-outflow view at 30-60°. The probe is then withdrawn and the angle of the array decreased to 0-20° to view the MPA bifurcation.

Figure 1. TOE image of femoral venous drainage catheter in the bicaval view. The cannula can be seen to enter the RA via the IVC. LA - left atrium. RA - Right atrium. SVC - Superior vena cava. IVC - inferior vena cava.

Figure 2. TOE image of the placement of the coronary sinus catheter in a modified bicaval view. The coronary sinus catheter balloon can be seen in the entrance to the coronary sinus. LA - left atrium. RA - right atrium. CS - coronary sinus.

FAST-TRACKING IN MINIMALLY INVASIVE AORTIC VALVE SURGERY

A fast-track approach has been shown to be equally safe and effective compared to 'standard' care in terms of morbidity and mortality, but with shorter extubation times and intensive care unit stays [2]. These shorter ICU stays have not yet led to a shorter hospital stay [3] showing that extubation *per se* is not the rate limiting step of intensive care discharge. Indeed patients who fail the fast-track stream may have longer stays than if they were in a 'standard' stream [3].

There is currently no level I evidence as yet pertaining to fast-track minimal invasive aortic valve surgery. However, when designing a fast-track protocol for minimally invasive aortic valve surgery, the same empiric principles will apply.

There is no standard definition of what constitutes fast-track aortic valve surgery [2], but it is this authors opinion that the drive should be towards improving patient care and experience; efficiencies to the healthcare system will come as a by-product of providing this high-quality care. A fast-track system should address the whole peri-operative pathway, from patient selection and pre-admission to hospital discharge and follow-up.

Enhanced Recovery

The stage beyond fast-track aortic valve surgery is enhanced recovery (ER). ER is a programme of high quality surgical care that returns patients back to normal function sooner.

ER and minimally invasive surgery are inter-dependent: ER cannot occur without less tissue damage and a smaller and shorter inflammatory response. Similarly, the benefits of minimally invasive aortic valve surgery will fail to be realised without a system change that moves patients through that system faster.

ER works on the principle of “the aggregation of marginal gains” [4]. This means making every part of the peri-operative care pathway as good as it possibly can be for as many patients as possible. The higher the rate of compliance with the elements of the ER, the lower the rate of later than expected discharges (Joshi et al. ACTA Manchester 2015 In press).

There are four elements to an enhanced recovery programme:

1. Pre-operative assessment, planning and preparation before admission: It is important to involve the patient, their family and their careers in the operation, as well as the patient’s General Practitioner. This means that that the dates for admission, operation AND expected discharge are in everyone’s diary. Planning and maintaining a date for operation and discharge makes sure that staff identify and co-ordinate all essential resources. Pre-operative assessment should be made as soon as the decision to operate has been made. This allows all relevant investigations and consultations to be complete by the time of surgery.
2. Reducing the physical stress of the operation: Using minimally invasive surgery, maintaining adequate temperature and optimal fluid management.
3. A structured approach to immediate post-operative and peri-operative management, including pain relief. Structured and protocol driven post-operative care is essential, not only as it ensures that patients are getting the right care, but will identify patients who are failing the pathway. This will allow early intervention to treat these problems.
4. Early mobilisation: This is dependent on high quality analgesia and structured physiotherapy. Patients should be ambulated at the earliest opportunity.

Key factors that help implement an enhanced recovery programme are:

- Staff training: The multi-disciplinary team must be trained so that they understand the evidence about speeding up recovery after surgery and thus develop a mind-set which allows patients to be active in their recovery. Operating theatre staff needs to be formally trained in minimally invasive aortic valve techniques to ensure smooth process of the operation and keeping operating and cross-clamp times to a minimum.
- Improved processes: The workflow should be planned and scheduled. This means everybody knows what to expect and when to expect it.
- Procedure specific care plans: A generic ‘cardiac surgery’ care plan is no longer appropriate. MIAVR care plans should be separate from mitral valve repairs and coronary artery surgery. The pre-, peri- and post-operative goals are different and therefore should be treated differently. This not only allows early identification of those who are failing, but also allows advanced planning (e.g., pre-discharge echo, optimal anti-coagulation) to ensure discharges are timely.

CONCLUSION

Meticulous attention must be given by the anaesthetist and/or the intensivist to anaesthetic methods, analgesic techniques and anatomical/echocardiographic considerations before, during and after minimally invasive aortic valve surgery to avoid complications, enhance quicker recovery, avoid pain and earlier discharge from the hospital. Fast-track protocols should be devised and followed for suitable patients.

Chapter 401

CANNULATION AND CARDIO-PULMONARY BYPASS FOR MINIMALLY INVASIVE AORTIC VALVE SURGERY

Martin Andreas, Guenther Laufer and Alfred Kocher*

Department of Cardiac Surgery, Medical University of Vienna,
Vienna, Austria

ABSTRACT

Cannulation and cardio-pulmonary bypass deserves distinct attention in patients undergoing minimally invasive aortic valve surgery. Meticulous care and attention has to be paid to every detail from pre-operative planning throughout the surgical procedure until post-operative care. This chapter provides several practical tips and a step-by-step guide to successful and minimal-risk cannulation for optimal conduct of cardio-pulmonary bypass. The pros and cons of different techniques are discussed to provide the reader relevant background information for clinical decision making.

Keywords: cannulation, hemi-sternotomy, anterior right thoracotomy, minimally invasive

INTRODUCTION

The cannulation strategy – which is the topic of the current chapter - may differ depending on access for valve surgery. This book chapter focuses on the two most commonly applied minimally invasive strategies for aortic valve replacement (AVR), namely anterior right thoracotomy (ART) and upper hemisternotomy (UHS) [1]. UHS is less complex regarding cannulation and cardio-pulmonary bypass (CPB) compared to ART. The most commonly performed UHS is the reversed-L-shaped (or ‘J’ shaped) into the right 3rd or 4th intercostal space [2]. While UHS can be performed with a routine set of cannulas, ART requires different arterial and venous cannulae. Furthermore, aortic cross-clamping, venting, cardioplegic arrest and de-airing may undergo significant adaptations from UHS to ART.

* Corresponding Author's Email: Alfred.Kocher@meduniwien.ac.at; Fax: +43 1 404005640.

This chapter describes current techniques for cannulation and CPB applied at the Medical University of Vienna. Most techniques for direct cannulation via ART were implemented at our department by Prof. Guenther Laufer (Head of Department).

Stable CPB is an absolute requirement for a safe and successful surgical procedure. The calculated flow must be achieved and optimal drainage is crucial to optimise exposure in these surgical procedures. Literally every millimeter is essential in minimally invasive aortic valve surgery. A stepwise approach may be selected during the implementation of a minimally invasive program at a department or during the training of younger surgeons. This could include cannulation via the groin or the axillary artery during the early period of ART aortic valve surgery to optimise exposure through limited access. A switch to intra-thoracic cannulation may be performed after more surgical experience is achieved.

PATIENT SELECTION

Patients have to fulfill distinct criteria to be eligible for minimally invasive aortic valve surgery. Some of the criteria are also related to cannulation.

Indication for Aortic Valve Surgery

The underlying aortic valve disease may influence the decision regarding the surgical access. Aortic stenosis without other co-morbidities may be ideal for minimally invasive AVR. On the contrary, pure aortic regurgitation (AR) may add complexity to the procedure. Here, the aorta may be dilated and highly pulsatile prior to cross-clamping, which may make suture placement and aortic clamping more challenging. Furthermore, administration of cardioplegia will lead to regurgitation into the ventricle and may cause ventricular dilatation and impaired cardio-protection. Direct coronary intubation and administration of cardioplegia will be necessary in these patients. Furthermore, rapid-deployment valves are not always suitable in these patients.

Patients suffering from active endocarditis of the aortic valve should not be approached by ART due to the potential additional procedures that may be required to reconstruct the left ventricular outflow tract. However, UHS could be chosen after intense review of the trans-oesophageal echocardiogram showing no abscess formation in the aortic root and no involvement of other valves in these patients.

Additional attention should also be paid to younger patients with AR. They may benefit from aortic valve reconstruction or a Ross procedure [3]. Although aortic valve reconstruction has also been performed via ART previously, we do not recommend this approach in patients who have a planned aortic valve reconstruction.

Concomitant Procedures

Patients selected for minimally invasive aortic valve surgery should not have an indication for additional procedures. However, an aortic reduction plasty or even a Bentall procedure may be performed via UHS in selected patients.

Patients with an untreated significant coronary artery disease should not undergo minimally invasive aortic valve surgery. A coronary bypass should be performed during the same procedure. Furthermore, we do not recommend to treat coronary artery stenosis by stenting to enable minimally invasive valve surgery. However, other authors may accept low risk stenosis for prior stenting in selected patients [1]. In addition, Lewis et al reported two cases with significant stenosis of the proximal right coronary artery who underwent bypass surgery via ART in addition to minimally invasive aortic valve surgery[4].

Patients who require a MAZE procedure or an additional valve procedure are not suitable for minimally invasive surgery.

Re-Operative Aortic Valve Surgery

Minimally invasive surgery for AVR has been applied in re-operative surgery in patients with previous bypass or valve surgery [5]. Potential advantages are less invasiveness with reduced blood loss. However, several technical modifications are required for this approach. The margin for surgical error is small and we do not recommend this during the early phases of a minimally invasive program.

Previous Non-Cardiac Procedures

All previously performed non-cardiac procedures have to be recorded for procedural planning and screened for a potential influence on the surgical strategy and the preferred cannulation technique. Previous ilio-femoral bypass surgery, stenting of the abdominal aorta or an abdominal aortic aneurysm may prohibit femoral arterial cannulation. A previously implanted cava umbrella may likewise represent a contraindication for femoral venous cannulation.

Thoracic Anatomy

Patients with a funnel – chest or other deformities should not undergo minimally invasive aortic valve surgery (distinct exceptions should be evaluated with special prudence) [1].

PREOPERATIVE PLANNING

Patients selected for minimally invasive aortic valve surgery require intense pre-operative planning to provide optimal access and avoid adverse events. Some prohibitive patient

characteristics have been described in the previous section. It is essential to obtain a detailed medical history by a surgical experienced fellow or consultant to gather all information relevant for the planning of a minimally invasive procedure. Furthermore, we recommend a preoperative ECG-gated computed tomography (CT) scan with contrast dye in every patient without a contraindication [6].

The pre-operative CT scan provides several relevant information for minimally invasive aortic valve surgery. The thoracic anatomy and the relation of the aorta and the aortic valve to the thoracic bone structures should be assessed [1]. Furthermore, optimal cannulation and cardio-protection strategies can be planned with a pre-operative CT scan [7]. This may influence the intercostal space approached for ART or UHS. We perform the L-shaped incision to the right thoracic side (reversed-L). However, some surgeons recommend performing the L-shaped incision to the left thoracic side for better exposure. This may be true in selected patients and a CT scan can identify these specific patients. There are a few patients where an inverse T is necessary to gain optimal exposure.

The distance from the intercostal space opened during ART and the aorta for cannulation and the aortic valve for AVR should also be evaluated with a pre-operative CT scan. Glauber et al [8] defined patients eligible for ART if ‘more than half of the ascending aorta is located on the right in respect to a vertical line drawn from the right sternal border to the ascending aorta’ and if ‘the distance from the ascending aorta to the sternum does not exceed 10 cm’. However, patients not fulfilling these criteria may be approached via ART according to surgeons’ choice with adapted procedural steps. We recommend switching the intercostal space to the third intercostal space with a transection of the third rib in patients with a caudal aortic valve.

A detailed analysis of the aorta and the great vessels should be performed in every patient. This should include the screening for severe calcification in the ascending aorta, which may represent a contraindication for cross-clamping and also calcification of the groin vessels in patients with planned cannulation through the femoral artery. Furthermore, relevant stenosis should be detected and also addressed prior to surgery whenever possible. The application of contrast dye during an ECG gated CT scan enables the detection of soft plaques and potential other sources of emboli. Soft plaques or mobile thrombotic structures may be a contraindication for clamping of the ascending aorta depending on their localisation. The ascending aorta is not a routine spot of severe calcification. The aortic arch and the descending thoracic aorta are more commonly affected by severe calcifications, soft-plaques and mobile thrombotic structures. These may be dislodged with a cannulation of the aorta by an arterial cannula via Seldinger technique in patients undergoing minimally invasive aortic valve surgery via ART.

CANNULAE FOR MINIMALLY INVASIVE AORTIC VALVE SURGERY

We have provided a short-list of available cannulas in Table 1-3. These are recommendations retrieved from relevant literature and our own experience. However, this list is not considered complete and should only be used for reference purposes only.

Table 1. Arterial cannulae for minimally invasive aortic valve surgery

Name	Sizes in French	Company	Access	Reference
OptiSite	18, 20, 22	Edwards Lifesciences, Irvine, CA, USA	UHS	(Malaisrie et al.)
Sarns Soft-Flow	21, 24	Terumo Cardiovascular Systems, Ann Arbor, MI, USA	UHS	(Malaisrie et al.)
Curved tip	22	Medtronic, Minneapolis, MN, USA	UHS	Vienna
Fem-Flex II	14, 16, 18, 20	Edwards Lifesciences, Irvine, CA, USA	ART	(Malaisrie et al.)
Bio-Medicus	17, 19, 21	Medtronic, Minneapolis, MN, USA	ART	(Malaisrie et al.), Vienna

Table 2. Venous cannulae for minimally invasive aortic valve surgery

Name	Size in French	Company	Access	Reference
Thin-Flex	-	Edwards Lifesciences, Irvine, CA, USA	UHS	(Malaisrie et al.)
MC2X	29/46/37	Medtronic, Minneapolis, MN, USA	UHS	(Malaisrie et al.)
Three-stage	-	Terumo Cardiovascular Systems, Ann Arbor, MI, USA	UHS	(Malaisrie et al.)
Single Stage Venous Cannula (Ref 67536)	36	Medtronic, Minneapolis, MN, USA	ART (thoracic)/ UHS	Vienna
QuickDraw	22, 25	Edwards Lifesciences, Irvine, CA, USA	ART (groin)	(Malaisrie et al.)

Remote Access Perfusion Femoral Venous cannula, RAP FV	-	Estech Inc, San Ramon, CA, USA	ART (groin)	(Schachner et al.; Murzi et al.)
Smart cannula	-	Smart- cannula LLC, Lausanne, Switzerland	ART (groin)	(von Segesser et al.)

Upper Hemi-Sternotomy

Standard arterial and venous cannulae can be applied for AVR via UHS. However, a bulky venous cannula should be avoided to provide maximal space for the surgical procedure. Vaughan et al [9] report good drainage with a low-profile three-stage venous cannula (Medtronic MC2X, Medtronic Inc, USA). A straight arterial cannula may be used to cannulate the aortic arch in Seldinger technique for patients requiring an additional procedure of the ascending aorta in selected cases. A list of recommended cannulae is presented in Table 1 for arterial cannulation and in Table 2 for venous cannulation. The venous cannula should be fixated with a pericardial stay suture at the right lower corner of the operative field to optimise surgical exposure and drainage.

Anterior Right Thoracotomy

Cannulation for aortic valve surgery via ART requires special cannulae (Table 1-3). Arterial cannulae are rather uniform. Standard multiside-hole cannulas may be used for femoral cannulation. Non-heparinized cannulae are available in addition to ECMO cannulae at a lower price and can be used without restraint in this case.

Table 3. Vents and cardioplegia cannulae

Name	Type	Company	Access	Reference
ProPlege peripheral retrograde cardioplegia device	Peripheral retrograde cardioplegia device	Edwards Lifesciences, Irvine, CA, USA	UHS/ART	(Malaisrie et al.)
EndoVent pulmonary catheter	Peripheral pulmonary vent	Edwards Lifesciences, Irvine, CA, USA	UHS/ART	(Malaisrie et al.)
Aortic Root Cannula	Aortic root cannula with vent line (Ref: 20012)	Medtronic, Minneapolis, MN, USA	UHS	Vienna
Left heart vent catheter	Soft and flexible vent (Ref 12016)	Medtronic, Minneapolis, MN, USA	UHS/ART	Vienna
Tourniquet Kit	(Ref 79006)	Medtronic, Minneapolis, MN, USA	UHS/ART	Vienna

Venous cannulae are available in different sizes and shapes (Table 2). Some cannulae have special design elements for optimal drainage. The Estech RAP cannula (Remote Access Perfusion Femoral Venous cannula, RAP FV; Estech Inc, USA) has two areas of venous inflow providing venting directly from the superior and inferior venous system [10-11]. Other similar approaches are available with a multi-stage cannula (Bio-Medicus Multi-Stage Venous Cannula, Medtronic Inc, USA) or a self-expanding venous cannula, providing optimal drainage of all venous vessels due to “stenting” of the venous system [12].

A vent should be used to provide optimal visualisation of the surgical field (Table 3). The vent may be applied directly through the aortic valve, through the pulmonary artery or through the right upper pulmonary vein. The latter allows the venting of the left ventricle, if the vent was advanced through the mitral valve. This may be of importance during administration of cardioplegia, for de-airing and after removal of the aortic cross clamp in cases of ventricular fibrillation.

Cardioplegia may be applied through a plastic aortic cannula or a longer metal cannula (Table 3). A single-shot Bretschneider’s solution is highly recommended in routine cases of minimally invasive aortic valve surgery. Direct application into the coronary ostia is possible in cases of relevant AR. However, an application through the aortic root should be the primary approach. The aorta has to be opened rapidly in cases of ventricular distension and a direct coronary administration is then continued.

Retrograde cardioplegia can also be applied in selected patients undergoing AVR for AR via UHS. However, the administration of the retrograde catheter may not always be possible and needs echocardiographic guidance.

SPECIAL REQUIREMENTS DURING CARDIO-PULMONARY BYPASS

Additional monitoring may be required due to the cannulation technique. An arterial cannulation via the common femoral artery should prompt a pulse oxygenation monitoring of the limb [1]. An axillary arterial cannulation requires an additional pressure line for the right arm. Although not described in detail in this chapter, introduction of a cannula for retrograde cardioplegia and a second cannula for venting via the pulmonary artery is possible through the jugular vein (Table 3).

The required pump flow is calculated according to the patient's body surface area. Although several components influence the maximum flow achieved by the perfusion system, venous drainage has the most significant impact [13]. Minimally invasive cardiac surgery includes cannulation techniques with miniaturised cannulae. Therefore, specific details have to be followed to provide sufficient pump flow. Bad drainage is one of the big obstacles in minimally invasive aortic valve surgery due to the impaired exposure of the surgical field. The meticulous placement of venous cannulae is of major importance to optimise drainage. Therefore, we recommend re-arrangement of cannulae prior to aortic clamping in cases of insufficient drainage to save time during the main parts of the surgical procedure. In addition, vacuum-assisted drainage is at least required in patients with a higher body surface area despite optimal cannulation [9]. Low vacuum may improve drainage in every patient, but high vacuum suction causes air embolism and haemolysis [13].

A further relevant detail is the temperature management during minimally invasive aortic valve surgery. The arrested heart has increased contact to the adjacent organs compared to full sternotomy. Furthermore, topical cooling by cold saline cannot be applied as easy as in patients with full sternotomy. Therefore, cooling of the patient during the surgical procedure may improve cardio-protection. Due to the lack of retrograde repetitive cardioplegia, which can be applied more easily during aortic valve procedures in patients with full sternotomy, the myocardial cooling is additionally impaired. Although institutional protocols should be adapted to the current practice, we recommend a cooling towards 34°C body temperature in UHS and to 32°C in ART cases. The difference in the recommended target temperature is mainly due to the duration of aortic cross-clamping, which is longer in ART.

CARDIOPLEGIC SOLUTIONS FOR MINIMALLY INVASIVE AORTIC VALVE SURGERY

Bretschneider's HTK cardioplegic solution (HTK – histidine-tryptophan-ketoglutarate) is the preferred cardioplegic approach in patients undergoing minimally invasive aortic valve surgery at our centre. HTK removes Na^+ and Ca^{2+} from the extracellular tissue and thereby avoids an action potential without changing the resting membrane potential. It has a low K^+ concentration, which permits the administration of a higher amount (about 2 litres) only once during surgery directly after aortic cross-clamping. Therefore, repetitive dosing and retrograde application are not required with this approach. However, the high amount of administered additional fluid during a short period of time may cause volume overload. Therefore, we recommend haemofiltration during CPB to remove the administered fluid whenever possible prior to discontinuation of CPB.

Routine cold blood cardioplegia is applied by other groups in patients undergoing aortic valve surgery via UHS after placement of a retrograde cardioplegic catheter. The repeated application of blood cardioplegia is also possible via direct cannulation of the coronary ostia. However, this may significantly prolong the surgical procedure.

CANNULATION VIA UPPER HEMI-STERNOTOMY

Cannulation for patients undergoing aortic valve surgery via UHS can be performed in a rather comparable way to full sternotomy. The pericardium is opened after reversed-L-shaped UHS. The pre-pericardial fat should be resected in patients with limited exposure without injuring the innominate vein or opening a pleural space. The pericardial sac is opened and stay sutures are placed. To improve the exposure at this step, the sternal spreader could be removed, the stay sutures re-fixated with clamps at the surgical dressing and the spreader is replaced thereafter [1]. Two diamond – shaped purse-string sutures are then placed over the distal ascending aorta. The surgeon should feel for aortic calcifications prior to the selection of the cannulation site. A pre-operative CT scan is of major importance to identify soft plaques. Alternatively, an epi-aortic ultrasound can be applied to search for aortic soft plaques or calcifications. Cannulation of the aorta is performed after heparin administration and the minimum required period of activated-clotting-time has been achieved. The limited exposure may add some difficulties to direct cannulation. A set of sterile Hegar dilators should be available on the table in the case of complicated cannulation.

Two different strategies are favoured for venous cannulation in patients operated via UHS. Some authors favour the optimal visualisation with percutaneous femoral venous cannulation [14,15], whereas others rely on direct atrial cannulation without the need of femoral cannulation [16,17]. We also recommend the latter approach. One purse-string suture is placed in the right atrium close to or in the right atrial appendage for venous cannulation. Some surgeons prefer to clamp the right atrial appendage prior to suture placement, cut the tip to the appendage and place the suture thereafter. This provides a better and more stable exposure, especially in cases with a deep right atrium. The surgeons hold both sides of the cut edge with forceps and venous cannula is placed. One has to be aware of the fact that correct placement of the cannula into the inferior caval vein cannot be verified by palpation.

A vent is applied through the right upper pulmonary vein and advanced in the left ventricle. The CO₂ inflation should be started prior to vent placement with 2 litres/minute to avoid air embolism. A simple U-stitch with a 4-0 prolene suture is sufficient. The vein is incised with an 11 blade and the hole is widened with instrument. The vent is placed using a forceps for guidance.

The aorta is separated from the pulmonary artery after CPB is established. The Y-shaped cannula for cardioplegia and venting is placed at a position rather distal at the highest point of the ascending aorta to allow de-airing after AVR through the vent line.

CANNULATION VIA THE GROIN FOR ANTERIOR RIGHT THORACOTOMY

Several surgical details have to be taken into account for safe cannulation of the groin. Potential adverse events are bleeding, local dissection, traumatic vessel injury, retrograde aortic dissection, seroma, lymph fistula, pseudo-aneurysm and infection [18]. Aortic dissection has an incidence of 0.9% in a large retrospective study and is a major drawback of this approach [18]. However, this study applied aortic endo-clamping, which has the potential to cause either direct aortic dissection or retrograde aortic dissection due to jet lesions at the inflow cannula. Therefore, we do not recommend the use of an endoclamp system. In general, a number of complications can be avoided by direct cannulation via ART. However, some anatomical settings and early phases in a minimally invasive program require cannulation in the groin. A pre-operative CT scan including the femoral vessels helps to select the left or the right side for cannulation and the optimal shape and size of cannulae [18]. If both sides are available for cannulation, the right side should be used.

The skin incision should be performed after palpation of the arterial pulse. We align the direction of the skin incision along the direction of the inguinal ligament. The incision should be performed about 1-2 cm cranial to the groin crease to reduce the likelihood of infection. Reduce the length of the incision to 4 cm. The vessels are revealed right below the inguinal ligament. However, only the frontal plane of the vessels is prepared. We do not recommend placing vessel loops around the vessels, as this increases the risk of lymph fistula. A double 5-0 prolene purse-string suture is placed on both vessels in a quadrangular longitudinal shape to avoid vessel stenosis. At this step, the thoracic incision is performed and the thorax is opened prior to heparin administration. The femoral artery is punctured at the caudal end of the purse-string suture after heparin administration and a J-tipped guidewire is advanced into the aorta under echocardiographic control. The cannula is inserted by Seldinger technique after confirmation of the correct guidewire position. Thereafter, the venous cannula is inserted in the same way. The arterial cannula is secured with three silk sutures. Consider a second 14-gauge arterial cannula for limb perfusion in patients with a drop of oxygen saturation measured at the limb during CPB. The venous cannula should not be secured directly after cannulation. This enables the re-adjustment of the cannula position in patients with insufficient venous drainage.

A vent can be placed in the right upper pulmonary vein through the thoracotomy or through an extra thoracic incision. Alternatively, an endo-vent can be placed via the jugular vein into the pulmonary artery.

DIRECT CANNULATION VIA ANTERIOR RIGHT THORACOTOMY

Direct cannulation in patients undergoing ART is possible for experienced surgeons and should be favoured whenever possible. The cannulation process starts directly after the thoracotomy is performed. A second incision about 1.5 cm is performed in the sub-mammary fold. A tunnel is prepared through the 4th or 5th intercostal space. Thereafter, a 36 French angled venous cannula is cut at the connection end to create a rather pointed tip (Figure 1, Table 2). Thereafter, the cannula is brought through the thorax, the tip is cut straight again

and any foreign material is removed from the inside of the cannula. After that, the soft-tissue retractor can be placed and the pericardium is opened after heparin administration. The aortic pressure should be directed to a mean pressure of about 80 mmHg at this step of cannulation. This enables some mobility of the ascending aorta during arterial cannulation but provides the necessary counter-pressure for cannula insertion. We use a standard multiside-hole arterial cannula although direct straight arterial cannulas without a soft part at the end are available (Figure 2, Table 1).

Figure 1. Preparation of the venous cannula for anterior right thoracotomy. Caption: The tip of the cannula is cut to ease transthoracic placement in patients undergoing aortic valve replacement via anterior right thoracotomy and intrathoracic cannulation.

Figure 2. Cannula – placement for intrathoracic cannulation via anterior right thoracotomy. Caption: The first figure shows the cannula prior to placement. The venous cannula should be placed through the thorax prior to arterial cannulation.

We suggest that the cannulation is safer if the arterial cannula can be advanced some centimetres into the thoracic aorta to avoid unintended dislodgement. Two 3-0 prolene purse string sutures are inserted on the ascending aorta for cannulation. It is important to avoid transmural stitches, as any bleeding will increase the difficulty of the whole procedure. A guide-wire is advanced through a puncture needle. The correct placement of the guide-wire in the descending aorta is confirmed by trans-oesophageal echocardiography. The tip of the cannula should be inserted until it passes the origin of the left subclavian artery to avoid any unintended dislodgement into a branch vessel. The cannula is secured with a heavy silk suture to the left upper margin of the incision. Thereafter, a purse-string suture is placed at the right atrial appendage. A clamp should be used to stabilise the appendage and optimise visualisation. The atrial appendage is cut and a purse-string suture is placed. Two forceps hold the appendage, the clamp is released and the angled 36 French cannula is advanced into the right atrium. The tourniquet for the purse-string suture is secured with clips and brought into the thorax (Figure 2, Table 3). Slight tension on the cannula optimises the surgical field and opens the space between atrial appendage and aorta. A vent is placed thereafter through the right upper pulmonary vein with a pledgeted prolene suture (Figure 3). The aorta is clamped with a Chitwood clamp [19]. The correct position of the clamp in the Transverse sinus has to be confirmed prior to clamping. The final valve exposure is shown in Figure 4.

Figure 3. Vent for placement through the right upper pulmonary vein. Caption: The vent should be bent in this form to facilitate intra-ventricular placement.

Figure 4. Exposure of the aortic valve via anterior right thoracotomy. Caption: The aortic cross clamp is placed through the transverse sinus. Optimal exposure includes the placement of three commissural sutures.

DECANNULATION – EVERY STEP IS RELEVANT

The aorta is closed by prolene sutures according to the preference of the surgeon. However, de-airing should be performed prior to the tying of the aortic suture to remove air and potential debris originating from the decalcification process. The vent is stopped for de-airing, venous drainage is reduced and the heart is filled. The lungs should be ventilated at higher pressure. The patient's chest is compressed repeatedly to compress the heart. The aortic suture is finished thereafter. Now, chest tubes and pacemaker wires should be placed. Then, the de-airing process should be repeated via the Y – shaped arterial cardioplegic cannula in UHS patients or via the hole left after cardioplegia application via the metal needle in ART patients. The aortic cross – clamp is removed thereafter. The hole should be closed thereafter with a pledgeted prolene suture.

It is important to place external defibrillator pads in every patient undergoing minimally invasive aortic valve surgery. The lungs should be ventilated prior to external defibrillation after aortic de-clamping.

The vent can be removed after the heart is beating in sinus rhythm and the venous cannula can be removed after CPB is stopped and the patient is stable. A chest tube can be placed in patients operated via ART via the 36 French cannula. Every cannulation site should be secured with an additional suture after removal of the cannula. The aortic cannula is removed after full protamine administration in a stable patient.

CONCLUSION

Cannulation for minimally invasive aortic valve surgery requires detailed preparation and meticulous conduct to avoid complications and provide optimal exposure for valve surgery. A stepwise approach from UHS to direct cannulation via ART should be followed during the

training period of every surgeon willing to conduct the full spectrum of minimally invasive aortic valve surgery.

Charlottesville, VA, US

ABSTRACT

There has been increasing interest in minimally invasive approaches to cardiac surgery, specifically with regard to the management of aortic valve disease. There are various minimally invasive surgical options, of which, an upper hemi-sternotomy has emerged as one of the most reliable approaches. Patients benefit from this operation with shorter hospital and intensive care unit stays, reduced surgical trauma and the potential for reduced total cost. More recently, the synergism of minimal surgical access with rapidly deployable valves has leveraged the potential benefits of these innovations. In this chapter our approach to, and technical considerations for minimally invasive aortic valve replacement through an upper hemi-sternotomy are outlined. Further, a brief history of the development of these techniques, the outcomes for minimally invasive aortic valve replacement surgery, and future directions are discussed.

Keywords: aortic valve, minimally invasive, hemisternotomy, sutureless cardiac valves

INTRODUCTION

Open surgical aortic valve replacement (AVR) through a sternotomy has been the standard of care for the treatment of aortic valve pathology for decades. Although there is a long history of both its safety and efficacy, the recovery period is substantial and patients require many weeks of restriction prior to returning to full physical activity and work.

* Corresponding Author's Email: gorav@virginia.edu; Fax: 434-244-7588.

The advent of novel surgical approaches with smaller incisions in the 1990s, was met with tempered enthusiasm due to concerns over wound healing and vascular complications. More recently, there has been growing interest in less invasive approaches to valve replacement. Two main approaches have emerged as the operations of choice: anterior right mini-thoracotomy (ART) and upper hemisternotomy (UHS). The preferred approach is often surgeon specific, but there are advantages and disadvantages for each operation, as well as patient characteristics that influence the ideal surgical approach. Despite nearly 20-year experience with these techniques, widespread adoption has not been realised. Technical challenges and concerns about longer operative times still remain. The introduction of rapidly deployable, sutureless bioprosthetic valves may be ideally suited for less invasive approaches. When combined with a minimally invasive surgical approach, these novel valves may negate the concerns surrounding longer operative and ischemic times. Interest in minimally invasive surgical options has seen resurgence, both with the development of time saving devices, and as an alternative to the expanding indications for percutaneous catheter based intervention.

In this chapter, we will discuss both the technical aspects and clinical results of the UHS approach to minimally invasive AVR (MIAVR).

HEMISTERNOTOMY FOR MINIMALLY INVASIVE AORTIC VALVE REPLACEMENT

Preoperative Evaluation

The preoperative evaluation for patients that will undergo AVR via an UHS is similar to the evaluation for those that will undergo conventional full sternotomy. However, there are some notable points of emphasis that will be highlighted here. Evaluation for concomitant cerebrovascular and coronary artery disease should begin with appropriate risk stratification and completed with carotid artery duplex and cardiac catheterization if indicated. Significant coronary artery disease would preclude the feasibility of UHS as coronary artery bypass grafting cannot be readily performed through this approach. A non-contrast computed tomography (CT) scan of the chest is particularly important to aid in operative planning. This provides the surgeon with the precise anatomical location of the aortic valve in relation to the bony anatomy, which aids in the decision of which interspace (3rd vs. 4th) to extend the UHS. Moreover, this study will reveal areas of significant aortic atheromatous or calcific disease facilitating the formulation of cannulation and cross clamp strategies. Although central arterial cannulation is preferred, if peripheral arterial cannulation with retrograde perfusion is required, CT angiography of the aorta, iliac, and femoral vessels should be performed to evaluate for peripheral vascular disease.

Initial Operative Steps

The 3rd or 4th interspace is chosen based on preoperative CT imaging and proximity to the valve. A 5-6 cm skin incision is made, beginning just inferior to the sterno-manubrial junction and extended caudally. The subcutaneous tissue is dissected and skin undermined, exposing

the sternal notch and interspace, carefully dissecting off the internal thoracic pedicle. A sternal saw is used to create a J-sternotomy, beginning at the sternal notch and completed in the 3rd or 4th interspace typically to the patient's right (Figure 1). Rarely, an inverted "T" or "L" sternotomy is required if the aortic valve is positioned to the patient's left as assessed by CT scan. A small Finochietto type retractor is inserted and enables excellent visualisation for both surgeon and assistant (Figure 2).

Figure 1. Sternal incision for minimally invasive hemisternotomy (J-Sternotomy) extended through the 3rd or 4th interspace.

Figure 2. Operative view of ascending aorta through hemisternotomy.

The thymic fat is excised completely to ease in visualisation. The pericardium is opened and multiple pericardial sutures are placed on both sides and secured to the drapes with tension cradling the heart into the wound. Direct arterial cannulation of the distal ascending aorta is achieved in the standard fashion. The two major tenets of minimally invasive surgery are: 1) complete venous drainage, and 2) myocardial protection. Venous cannulation is established with a long, multi-stage venous cannula inserted in the femoral vein percutaneously using the Seldinger technique and trans-oesophageal echocardiography (TEE) guidance. Ideally, the tip of the cannula is placed into the SVC and can be retracted if

necessary. The size of the venous cannula is typically a 25F to optimize drainage. Carbon dioxide is used to flood the operative field to reduce the risk of air embolization.

Myocardial Protection

Myocardial protection is typically achieved by moderate hypothermia (33-35°C), delivery of antegrade cardioplegia using del Nido solution, and the application of topical ice. In cases where moderate or severe aortic valve insufficiency is present, a retrograde cardioplegia cannula is inserted into the coronary sinus via the right atrium, or more commonly, percutaneously via the right internal jugular vein by the anesthesiologist. Correct placement within the coronary sinus is confirmed with TEE. After initiation of bypass, a 13F left ventricular vent with a stylet is inserted through the right superior pulmonary vein. The aorta is cross-clamped directly and the clamp can be used to gently retract the heart superiorly. Topical ice is applied to the heart using a sterile teaspoon. In general, we utilize 1200-1500cc antegrade del Nido cardioplegia dependent upon the rapidity of arrest and redose every 60 minutes if required. If significant aortic insufficiency exists, retrograde cardioplegia or direct infusion with a hand-held catheter into both the left and right coronary systems is performed after opening the aorta.

Figure 3. Following aortotomy, three sutures are placed at the commissures and the valve is elevated to aid in exposure and excision.

Exposure and Valve Implantation

Once adequate arrest has been obtained, a transverse aortotomy is created with a curve cranially toward the left away from the pulmonary artery and the distal aortotomy is tacked to the superior extent of the pericardium. Stay sutures are placed at the commissures to aid in visualisation (Figure 3). The diseased native valve is excised with meticulous care given to the removal of debris from the operative field. Interrupted non-pledgeted horizontal mattress 2-0 sutures are placed in the annulus and then passed through the sewing ring of the prosthetic valve. Care is taken to properly seat the new valve within the annulus. The Cor-Knot system

(LSI Solutions, Victor, NY) is used to secure the valve in place often tacking the 3 commissure sutures first to ensure the valve seats properly. Although not commercially available in the U.S. and only in clinical trial, a sutureless bioprosthetic valve (3F (Medtronic, Minneapolis, MI), Perceval (LivaNova, London, UK) or INTUITY (Edwards, Irvine, CA)) may be employed. Following excision of the native tissue, the valve is placed into correct position, orientation and deployed.

Weaning from Cardiopulmonary Bypass

After the valve is sutured or secured in place, the aortotomy is closed, warm blood is administered into the aortic root with amiodarone, and pacing wires are placed on the RV prior to cross clamp removal. Warm blood can be administered for several minutes until return of sustainable native or paced cardiac rhythm prior to clamp removal. Due to limited access to the left ventricle for decompression, a particular concern is ventricular defibrillation. While pediatric paddles can be utilized, due to the small incision, we find that transcutaneous defibrillation is technically easier and should be performed with lung inflation. Ventricular distension should be a concern for paravalvular leak which occurs with similar infrequency as with conventional sternotomy. With rhythm achieved and cardiac and valvular function verified, the heart is de-aired through the aortic root with TOE guidance and various patient positions on the table. After weaning of bypass, the femoral venous cannula is removed and a simple silk stitch is used to aid in hemostasis. Manual compression is held until 10 minutes following the completion of protamine. The arterial cannula is removed following partial protamine administration.

Closure and Postoperative Management

Two silastic flexible drains are placed in the pericardium from the right chest. The pacing wires are passed through one of the chest tubes and separated outside of the skin. The UHS is re-approximated using stainless steel wires starting from inferiorly to superiorly. The first wire is placed one interspace lower on the patient's left hemisternum to the interspace above on the right. The second wire is placed across the same interspace one above the extent of the sternotomy. A sterile spoon is used to protect the right ventricle (RV) from the closing needle. Next, the soft tissue is closed in layers per usual. Patients are transported to the intensive care unit intubated. Freedom from mechanical ventilation is usually achieved in 2-4 hours and patients can often be transferred to the telemetry unit on post-operative day one. Although conventional sternal restrictions are employed, it is common that patients begin driving by 3 weeks postoperatively with return to work soon after.

TECHNICAL DEVELOPMENT AND CLINICAL OUTCOMES

The initial experience with MIAVR was via a right paramedian incision through the 3rd and 4th costal cartilages by Cosgrove and Sabik in 1996 [1]. Over the subsequent years,

interest in alternative access to the aortic valve burgeoned. Techniques were trialed across the world with no consensus on the ideal approach. At the World Congress on Minimally Invasive Cardiac Surgery in May of 1997 five different incisions were presented: 1) transverse sternotomy, 2) superior hemi-sternotomy, 3) inverted T, 4) J sternotomy and 5) parasternal (Figure 4) [2]. Despite dissention on the ideal approach, by the late 1990s, minimally invasive access was lauded as the future of cardiac surgery, citing improvement in patient satisfaction, more rapid improvement to normal function and reduced resource utilization [3-6]. In 1998, Cosgrove published the results of their initial 100 patients, and although major clinical outcomes were favorable, concern was raised at the instability that arose from the costo-sternal dissociation, the need for femoral arterial cannulation, and sacrifice of the right internal mammary artery [7]. As a result, their preferred approach shifted to an UHS. Since then, the UHS and ART have emerged as the two lasting alternatives to a traditional full sternotomy.

Figure 4. Minimally invasive approaches in use in the late 1990s: a) transverse sternotomy b) inverted T c) reversed L d) parasternal.

Although the UHS and ART are currently utilised as minimally invasive options, significant differences exist between the two approaches. The ART has the benefit of preserving the entirety of the sternum thus enabling potentially more rapid recovery and reducing wound complications, but it is not without its own limitations. Exposure is often more difficult and peripheral arterial cannulation is required. In a 2015 single intuition propensity matched study comparing 160 pairs, no difference was found in 90-day mortality between ART and UHS [8]. However, ART when compared to UHS, resulted in significantly

longer operative times (median cross clamp time 93 vs. 75 minutes; $p < 0.0001$, median cardiopulmonary bypass time 137 vs. 113 minutes; $p < 0.0001$), and significantly higher rates of conversion to full sternotomy, groin complications, and requirement for repeated cross clamping. At our institution, UHS is the approach of choice as the exposure affords both the attending surgeon and trainee an excellent operative view.

Clinical studies over the two decades have demonstrated excellent results when utilizing an UHS for isolated MIAVR. Specifically, similar operative mortality and long-term outcomes have been shown when compared to conventional sternotomy for AVR [9-12]. Moreover, there is the benefit of shorter intensive care and hospital stays despite the potential for longer operative times [6, 13-14]. Further, a higher percentage of patients are discharged home following MIAVR [15]. Rates of transfusion are decreased and post-operative pulmonary function is improved [13, 16]. Finally, it has been proven to be a reliable and versatile approach with safety demonstrated even in re-operative situations [17]. These clinical advantages of a mini sternotomy for AVR also result in financial benefit, with reduced total hospital costs [18].

In a 2009 systematic review and meta-analysis including 26 randomized and observational studies comparing UHS vs. conventional sternotomy, the benefits of UHS were highlighted [19]. Comparing a total of 2,054 UHS and 2,532 conventional AVR procedures, there was no difference in operative mortality despite longer cross clamp and cardiopulmonary bypass times (mean difference of 7.9 and 11.5 minutes respectively). The operative approach did not seem to influence rates of post-operative complications, including rates of atrial fibrillation, stroke and wound complications. However, ventilator time (2.1 hours), ICU length of stay (0.5 days), and hospital length of stay (0.9 days) were shorter with the UHS approach.

There have been a number of previous randomised trials comparing UHS to conventional sternotomy, which confirmed its safety and efficacy [10, 16, 21]. The initial randomized data was published in 1999 and included 120 patients that either underwent MIAVR by a surgeon who regularly performed this procedure or AVR through a conventional sternotomy [10]. A meaningful reduction in ventilator time, blood loss and analgesia use was seen. These results were confirmed by two later randomized trials, both demonstrated the ability to perform UHS without extending operative times [16, 21]. Collectively, these randomized trials were able to show the benefit of UHS, namely in the reduction in blood loss, post-operative pain and improvements in pulmonary function.

In recent years, the introduction of sutureless valves has emerged as a technology that may have synergistic benefits when combined with AVR through an UHS. Currently, there are three valves that are either available commercially (in Europe) or on an experimental protocol (in the U.S.) – INTUITY (Edwards, Irvine, CA), 3F Enable (Medtronic, Minneapolis, MN) and Perceval (LivaNova, London, UK) (Figure 5).

The INTUITY valve is based on the Magna Ease bioprosthetic, and is similarly constructed of bovine pericardium, but seated in a cloth-covered balloon expandable stainless steel frame. The 3F Enable aortic bioprosthesis is composed of a balloon expandable nitinol frame with three equal sections of equine pericardium [22]. The Perceval aortic valve is a self-expanding sutureless valve constructed of bovine pericardium mounted in a nitinol stent [23]. The feasibility of combining each of these valve with a minimally invasive approach has already been demonstrated and may resolve the concern for prolonged ischemic times. In 2015, the results of a randomized trial (CADENCE-MIS) comparing UHS utilizing the

INTUITY valve to a full sternotomy with standard bioprosthetic were published [20]. A total of 100 patients were randomized and their main findings were shorter cross clamp times (41.3 vs. 54.0 minutes; $p < 0.001$) and improved hemodynamic parameters (reduced mean transvalvular gradient 8.5 vs 10.3 mm Hg; $p = 0.044$) in the UHS arm. In 2010, the results of 22 patients implanted with the 3F Enable prosthesis through a UHS were reported with favorable and consistent outcomes [24]. Finally, a multicenter, prospective trial (CAVALIER) enrolled 658 patients to undergo implantation of the Perceval valve. In this cohort, 219 (33.3%) patients underwent a minimally invasive approach – the overwhelming majority (98.6%) through an UHS. This large trial demonstrated both the safety and efficacy of the Perceval valve when combined with a minimally invasive strategy [25]

Figure 5. Sutureless Aortic Valves: a) Edwards INTUITY b) Medtronic 3F and c) Sorin Perceval.

Since a minimally invasive approach to AVR was first introduced, there have been a number of technical advancements and innovative devices that continue to make this surgical option increasingly relevant and widely applicable. All patients that undergo isolated AVR should be considered for a minimally invasive option with careful attention to the relative contraindications of such a procedure including right ventricular dysfunction, significant aortic calcification, the need for concomitant coronary bypass surgery, reoperative situations with live bypass grafts and morbid obesity. Although a MIAVR may be the standard of care, there should be requirements for surgeons who wish to begin such a program. A consensus panel of experts has recently provided recommendations for its development [26]. It is prudent to have a significant volume of aortic valve disease and to simulate the exposure and set-up one would require for a minimally invasive operation. This ensures that the entire team, surgeon, anesthesiologist, perfusion and nursing are comfortable with the procedure and necessary adjuncts prior to initiation.

CONCLUSION

MIAVR provides excellent short-term and long-term results. There is reduced surgical trauma resulting in lower rates of blood loss, rates of transfusion and post-operative pain. Moreover, recovery is expedited with shorter intensive care stay, total hospital length of stay, and a more rapid return to baseline function. Respiratory function is improved with shorter requirements of mechanical ventilation, improved respiratory mechanics, and avoidance of

the disruption of diaphragm attachments to the lower sternum. Lingering concerns of longer operative appear to be well tolerated. Moreover, the recent advent of sutureless valves may mitigate this final concern.

Chapter 403

MINI-THORACOTOMY AORTIC VALVE SURGERY

Mattia Glauber, Antonio Miceli and Antonio Lio*

Cardiothoracic Center, Istituto Clinico Sant'Ambrogio,
Gruppo Ospedaliero San Donato, Milan, Italy

ABSTRACT

Although aortic valve replacement (AVR) via complete median sternotomy continues to be the 'gold standard' treatment for patients with aortic valve disease, several minimally invasive approaches have been recently developed. This chapter report technical details and postoperative outcomes of AVR through a right anterior mini-thoracotomy (ART). ART is associated with excellent results, reducing mortality and morbidity and allowing faster recovery, less blood transfusion, atrial fibrillation, shorter hospital stay and better cosmetics results. The introduction of sutureless prostheses has expanded indications for ART minimally invasive AVR and it has reduced the long operative times associated with these minimally invasive procedures.

Keywords: minimally invasive aortic valve replacement, right minithoracotomy, sutureless valve

INTRODUCTION

Aortic valve disease is a prevalent disorder that affects approximately 2% of the adult general population [1]; it is the most common valvular heart disease in developed countries and its incidence is likely to increase with age [2].

Aortic valve replacement (AVR) through a full sternotomy (FS) continues to be the conventional approach for the treatment of aortic valve disease with excellent short- and long-term outcomes. Data from the Society of Thoracic Surgeon (STS) database show a dramatically in-hospital mortality reduction from 3.4% in 1997 to 2.6% in 2006 for isolated AVR, although an increase in patients' profile risk [3]. Despite these excellent results, in

* Corresponding Author's Email: antoniolio@hotmail.it.

recent years, minimally invasive AVR (MIAVR) has gained consensus among surgeons; since 1993 several minimally invasive approaches (right parasternal approach, upper and lower ministernotomy, V-shaped, inverse-T, J- and reverse-L partial mini-sternotomy, transverse sternotomy, and right mini-thoracotomy) have been developed and have been associated with better outcomes and lower perioperative morbidity compared with FS [4-7]. Compared with conventional surgery, MIAVR has been shown to provide faster recovery, shorter hospital stay, improved cosmesis and less wound infection. In addition, MIAVR has shown to improve post-operative respiratory function due to the preservation of sternum, and reduction of post-operative pain, blood loss and blood transfusions related to the reduction of surgical dissection, as well as facilitating reoperation at a later date, as part of pericardium remains closed [8-12].

The most common minimally invasive technique for AVR has been the upper mini-sternotomy (UHS) approach, and the outcomes reported from several meta-analyses have focused mainly on this procedure [9, 10], although anterior right mini-thoracotomy (ART) has the potential to offer better outcomes.

The aim of this chapter is to report our experience with MIAVR through ART: our right thoracotomy program started in 2004 and now, after the introduction of the sutureless technology, it has become our first MIAVR access for approaching a patient with an aortic valve disease.

PATIENTS SELECTION AND PREOPERATIVE PLANNING

All patients planned for aortic valve surgery undergo imaging with a 64-slice computed tomography (CT) scanner without contrast enhancement. It is important that during the CT scanning, patient's arms are adducted, recreating the normal patient position on operative table. Images are elaborated in the coronal and sagittal planes and then reconstructed in a 3D format to evaluate the relationship among the intercostal spaces, ribs, sternum, ascending aorta and aortic valve.

Patients are considered suitable for ART if the following CT scan criteria were met: (1) at the level of the main pulmonary artery, the ascending aorta was rightward (more than one-half located on the right in respect to the right sternal border); (2) the distance from the ascending aorta to the sternum did not exceed 10 cm; (3) the angle between the ascending aorta and the patient's midline should be more than 45°.

The retrosternal position of the ascending aorta and the deep thorax were considered unfavourable anatomic conditions for the ART approach. However, in the sutureless era (since April 2011), these CT criteria have only relative importance for the choice of surgical approach, and not every patient meet them.

The exclusion criteria for ART are: previous right-side chest surgery; a history of right pleurisy or previous right-side pleural effusion with adhesion formation; severe chest wall deformities; severe pulmonary bullous disease; and the presence of an ascending aorta aneurysm or the technical impossibility of obtaining peripheral percutaneous venous cannulation.

SURGICAL TECHNIQUE

Anaesthesia is provided according the standard protocol for conventional AVR. The patient is positioned in a supine position and two defibrillator pads are placed across the chest wall for electrical conduction. A single lumen for intubation and a neckline for drugs infusion are used.

The minimally invasive procedure is performed through a skin incision of 5 cm placed at the level of the second intercostal space without rib resection. The right internal thoracic artery (RITA) is in older patients often sacrificed in order to achieve a better valve exposition and avoid bleeding complications; preservation of RITA is reserved for young patients with risk factors for coronary artery disease. A soft tissue is inserted into the thoracotomy and a small rib retractor is often used.

Once the lungs are off, the phrenic nerve is identified and the residual thymic tissue is removed up to the left innominate vein. The pericardium is usually opened 4-5 cm upper the phrenic nerve and above the ascending aorta. It is very important to retract the pericardium to allow the ascending aorta to come right forward and to obtain a better exposure. Once the pericardium is open, two concentric 2-0 polyester purse-string sutures for direct arterial cannulation are placed on the anterolateral portion of the distal ascending aorta with the second purse string reinforced with two pledgets. During the purse-string suture placement, the aorta can be kept steady using locking forceps to reduce physiological motion.

Figure 1. Preoperative chest computed tomography showing position of the ascending aorta in relation to the sternum. (A) retrosternal position of the ascending aorta (non suitable for ART); (B) right-sided ascending aorta (suitable for ART); (C, D) examples of deep thorax.

After heparin administration, venous cannulation is achieved using a BioMedicus Multistage (Medtronic, Inc., Minneapolis, MN, USA) or, in alternative, a RAP double stage 23-25 Fr (Sorin Group, Saluggia, Italy) inserted through the femoral vein into the right atrium with the Seldinger technique and under transoesophageal echocardiographic guidance. Thereafter, direct aortic cannulation is performed using a flexible cannula (Easyflow, Sorin Group, Saluggia, Italy).

On bypass a left ventricular vent is placed through the right superior pulmonary vein and a Y-shaped vent/cardioplegia positioned into the ascending aorta. Then, aorta is clamped with the aortic Glauber clamp (Cardiomedical GmbH, Langenhagen, Germany, distributed by Sorin, Saluggia, Italy). Antegrade cardioplegic solution is instilled into the aortic root or selectively into the coronary ostia using warm blood cardioplegia. Once the heart is arrested, aortotomy is performed and the operative field is flooded with carbon dioxide at a flow of 0.5 l/min. Aortotomy is performed differently depending on the type of prosthesis- sutured or sutureless/fast deployment valve- used.

In case of sutured valve implantation, a transverse aortotomy or an oblique aortotomy toward the non coronary sinus is performed. The diseased valve is removed and decalcification of the aortic annulus performed. Once the annulus is sized with appropriate valve sizer, stitches are passed through the aortic annulus in the following order: left coronary sinus, non coronary sinus and right coronary sinus. This because the right coronary sinus is more difficult to expose and we recommend passing the stitches after extending the aortic annulus. Once the stitches are passed through the bioprosthesis, the valve is parachuted down into the aortic root and then tied to the aortic annulus. If possible, we do not advise to tie the stitches with knot pusher as the fingers give a better sensation in control the knots.

In cases of sutureless valve implantation, Perceval S valve (Sorin Group) is the bioprosthesis of choice in our clinical practice, because it is a collapsible device. A collapsible profile, in ART AVR, seems to be the most useful and effective concept, enhancing visualisation in a reduced surgical exposure site and allowing the surgeon to secure correct position of the prosthesis under direct visual control before deployment.

In sutureless AVR, a smaller transverse aortotomy is performed at least 2 cm higher than conventional aortotomy, taking the inferior margin of Concato preaortic bundle as the reference point. The aortic annulus is sized with an ad hoc sizer, and then, three guiding 4/0 polypropylene sutures are placed at the nadir point of each valve sinus. The stitches are passed through the aortic annulus in the following order: right coronary sinus, non coronary sinus and the left coronary sinus. The Perceval S valve is collapsed and connected to the guiding sutures through the bottom holes placed on the inflow ring of the valve. Once the valve is parachuted into the aortic root, it is deployed and expanded with warm saline solution. Afterwards, the guiding sutures are removed and the valve is inspected; a correct position is achieved if the inflow ring of the sutureless valve covers the whole annulus and the coaptation of the three new leaflets figures a symmetrical Mercedes-Benz sign.

Rapid Deployment Edwards Intuity valve (Edwards Lifesciences, Irvine, CA, USA) can also be implanted via ART. A conventional aortotomy is performed, due to the non-collapsible profile of the device. After valve removal, the cylindrical end of an ad-hoc sizer is inserted through the annulus: the proper valve size is chosen when the flange of the sizer is not able to pass the aortic annulus. Then, three braided, non-pledgeted sutures are inserted as a figure-of-eight at the nadir of each aortic sinus. The sutures are passed through the sewing ring of the prosthesis and snared with a tourniquet and the valve is lowered into the annulus.

Therefore, it is mandatory to confirm that the valve stents lie completely within the aortic annulus; in minimally invasive procedures, due to the reduced visibility, a 5 mm-30° thoracoscope should be inserted through the holding device to confirm the correct position. Then, the valve is secured with the suture tourniquets and deployed. Finally, the three guiding sutures are tied and cut.

Figure 2. Final aesthetic result.

After an accurate aortotomy closure, before filling the heart and declamping the aorta a pace-maker wires should be placed before the heart starts to beat.

Figure 3. Surgical field of an ART AVR.

After deairing patient is weaned from cardiopulmonary bypass (CPB) and CPB is stopped. Trans-oesophageal echocardiography is performed to assess valve performance and correct position. For cannula removal, our protocol provides that the arterial cannula is removed first. At this time it is mandatory to induce systemic hypotension for closing the purse-strings. In case of need, like bleeding or haemodynamic instability, the venous cannula represents a rapid way to fill the patient. The femoral vein cannula is left in place to fill patients with residual blood in the cardiectomy. Once the reservoir is empty and for safety reason the venous

cannula needs to stay still in place, the mandrin can be reintroduced to avoid intralumen clotting. After protamine administration, the venous cannula is finally removed.

COMMENTS

MIAVR has become an alternative to standard sternotomy and it is increasingly performed in last years; compared to conventional surgery, MIAVR reduces postoperative morbidity and provides better cosmetic results [8-12].

Despite these positive results, the data reported from most of studies have focused on UHS. Few studies have evaluated the potential advantages of MIAVR using the ART approach.

We have described our first experience in 2011, reporting 192 consecutive patients who underwent isolate MIAVR through ART using stented valves from January 2005 to June 2010. Overall mortality was 1.6% and the rate of intraoperative conversion was 1.6%. The median of the length of stay was 5 days and discharge home was 90%. Interestingly, a low incidence of postoperative atrial fibrillation (AF) and blood transfusion were found (18% and 16%, respectively), nevertheless cross-clamp and CPB times were longer than in the standard approach [13].

Longer surgical times are considered an important drawback of ART, because of the negative impact on very old and fragile patients [14]. To overcome the technical challenges of MIAVR, and to shorten implantation time, a new generation of sutureless aortic valve prostheses have been introduced in clinical practice [15].

Since 2011, which is the year that clinical application of sutureless technology began at our Institution, there was a substantial increase in the number of patients that underwent ART AVR. Recently, we have reported a ten-year experience on 593 patients treated through a ART, showing a surgical mortality of 1.0% and an overall actuarial survival at 8-years of $93.3\% \pm 2\%$. Moreover, we showed that sutureless prostheses significantly reduce operative times and provide at least comparable clinical outcomes than conventional valves [16].

Figure 4. Intra-operative image showing central cannulation of the ascending aorta.

Advantages of ART approach over standard sternotomy were demonstrated by our group by a comparison with patients undergoing conventional surgery [17]. Specifically, 138 patients undergoing ART were matched to a full sternotomy group using propensity score analysis. The overall in-hospital mortality was 0.7%, with no difference between the two groups. MIAVR via ART was associated with a lower incidence of postoperative AF and blood transfusions compared to conventional surgery. In addition, patients in the ART group had a shorter mechanical ventilation time and postoperative length of stay.

Moreover, among patients undergoing MIAVR, the less surgical trauma induced by a minithoracotomy with sternal preservation might translate in lower postoperative morbidity. In a retrospective observational study, we have found that patients receiving a ART approach have better outcomes than those receiving mini-sternotomy, in terms of lower AF (19.5% vs 34.2%, $P = 0.01$), shorter ventilation time (median, 7 hours vs median, 8 hours, $P = 0.003$) and hospital stay (median, 5 days vs median, 6 days, $P = 0.0001$) [18].

Interestingly in all our studies, a low rate of atrial fibrillation was found to be associated with the ART approach. This might be related to a smaller pericardial incision and exposed area, as well as anatomical and electrical integrity of the percutaneously cannulated right atrium, which reduces the inflammatory response. In addition, an intact sternum would result in less postoperative pain, reducing the likelihood of AF.

Another criticism related to MIAVR regards the costs of surgical instrumentations. Although all the instruments and devices used for MIAVR are more expensive, we strongly believe that the less rate of postoperative complications, the shorter hospital stay and the faster recovery translate in less resources in the health system and therefore lower costs. However, this hypothesis should be evaluated with a well-designed study.

In the light of outstanding results that we have obtained in our 10-year experience with the ART AVR, MIAVR with sutureless prosthesis might be considered the real “alternative” to transcatheter aortic valve replacement (TAVR) procedure for high-risk patients judged still operable by a Heart Team.

Although TAVR represents the real MIAVR because it is performed without CPB, the main limitation of TAVR is that the native stenotic valve is left in place, resulting in a high degree of stroke and paravalvular leakage (PVL). We have recently demonstrated that high-risk patients undergoing MIAVR through ART using sutureless valves is associated with a trend of better early outcomes and mid-term survival with TAVR [19]. Specifically, in a small but matched population, the in-hospital mortality rate was 8.1% in the TAVI group and 0% in the ART group ($p = 0.25$), the incidence rate of stroke was 5.4% versus 0% in the TAVI and ART groups ($p = 0.3$). In the TAVR group, 37.8% and 27% had mild and moderate paravalvular leakage, whereas 2.7% had mild PVL in the ART group ($P < 0.001$). Finally, one- and 2-year survival rates were 91.6 vs 78.6% and 91.6 vs 66.2% in patients undergoing ART with the Perceval S sutureless valve compared with those undergoing TAVR ($p = 0.1$).

CONCLUSION

MIAVR performed through ART is a safe procedure associated with excellent postoperative outcomes, in terms of mortality, morbidity, shorter hospital stay and faster recovery. Sutureless technology have a potential to increase the adoption of MIAVR;

furthermore, the idea of minimal invasiveness regarding the surgical incision is complemented by reduced manipulation inside the aortic root, compared with a conventional sutured valve prosthesis implantation. The combination of MIAVR and sutureless prostheses may further improve postoperative outcomes, becoming the real alternative to TAVR procedure in the treatment of high operable risk patients affected by an aortic valve stenosis.

Chapter 404

RE-OPERATIVE MINIMALLY INVASIVE AORTIC VALVE SURGERY

Mauro Del Giglio and Elisa Mikus*, MD

Department of Cardiothoracic and Vascular Surgery,
Maria Cecilia Hospital, GVM Care and Research,
Cotignola (RA) GVM Care and Research, Italy

ABSTRACT

Minimally invasive surgery through an upper “J” ministernotomy (or upper hemi-sternotomy) for aortic valve replacement has become the routine approach in many centers with excellent results. However, the potential benefits of minimally invasive surgery in case of aortic valve re-operations remains questionable, especially in case of patent bypass grafts. All cardiac re-operations are associated with an increased peri-operative risk of morbidity and mortality when compared to the first operation. For this reason, the standard approach still utilises a full sternotomy and peripheral cannulation. On the other hand, employment of minimally invasive approaches in this situation, will result in minimal dissection of adhesions which may lead to reduced risk of bleeding and damage to a patent left internal mammary artery graft. This study compares the advantages and disadvantages of a minimally invasive approach in repeat aortic valve replacement compared to the standard approach, highlighting difficulties and potential solutions.

Keywords: aortic valve replacement, re-operative surgery, minimally invasive approach, upper “J” hemi-sternotomy, central cannulation.

INTRODUCTION

In 1962, Dr. Donald Ross in England reported the first successful aortic valve homograft implant [1]. Actually, aortic valve disease, especially stenotic calcific one, is the most

* Corresponding Author’s Email: elisamikus@yahoo.it; Fax: +39 (545) 217135.

common valvular heart disease in the aging population of the developed world. The conventional treatment of severe aortic valve disease is still surgical aortic valve replacement (AVR) through a median sternotomy, with complications and mortality decreasing in recent years [2]. However, in an era transformed by an aging population, the presenting patient is increasingly older and sicker [3, 4]. This is the reason why, a modern surgical challenge has triggered the development of less invasive procedures, assumed to diminish the operative risk.

Since the first report by Dr. Delos Cosgrove of the Cleveland Clinic Foundation in 1996, [5] the belief that minimally invasive aortic valve surgery could be performed with similar hospital mortality but more advantages (less blood transfusion, earlier recovery of daily activities, and higher patient satisfaction) compare to the standard approach, has driven its diffusion in most centers worldwide. Various techniques exist for minimally invasive aortic valve surgery: upper partial or hemi-sternotomy (UHS; J shaped or inverse-T, reverse C incision) and mini-thoracotomy in the right 2nd or 3rd intercostal space (anterior right thoracotomy; ART) [5-10]. In addition transcatheter aortic valve replacement has been developed in the last years.

Although a large volume of literature on primary minimally invasive AVR (MIAVR) is available, only a few studies have been reported on the use of this technique in patients who have undergone a previous cardiac surgical procedure [11]. In addition, the increasing life expectancy coupled with an ageing population is creating an increased need for cardiovascular disease treatment in very elderly patients and also in those who have already been subjected to cardiac surgery. The frequent use of biological prostheses may cause an additional enhancement in the number of aortic valve re-operations. This creates problems, given the need to reduce health system expenses through shorter hospital stays, less blood transfusions, and better postoperative outcomes by avoiding prolonged ventilation time and wound infections. To reach this goal, minimally invasive approach, through an upper “J” hemi-sternotomy (UHS), has been proposed also in case of re-operative AVR (rAVR) [12-14]. The surgical indications for surgery are the same of standard full sternotomy based on current guidelines [15] and no real contraindication exists for this kind of surgical approach except for the inability to perform minimally invasive valve surgery. Many advantages were reported for this technique attributable to the lesser dissection of mediastinal tissues, especially in cases of patent bypass grafts [16-19]. However, actually, the benchmark for rAVR is still the full sternotomy, often associated with a peripheral cannulation [15].

TECHNIQUE

During each surgical procedure, the operative technique and the surgeon’s expertise are most important in guiding the choices of materials, prosthesis and stitches to obtain the best clinical outcome. This is why appropriate training and adequate learning curve are essential. Minimally invasive rAVR (MlrAVR) is composed of many little steps, extracted from many clinical aspects and technical problems. Investing in surgeons’ technical abilities and in adequate training in minimally invasive field of young surgeons is the key to improve the clinical outcome. Here, advantages and disadvantages of minimally invasive approach are discussed elaborating some tricks to overcome difficulties.

The surgical technique adopted in our unit [15] consists of a small (5-7 cm) “J” shaped partial upper re-sternotomy performed in the 3rd right intercostal space through a 6 cm skin incision. A trans-oesophageal echocardiographic probe is placed in every patient.

Surgical dissection is mainly performed only on the right side of the surgical incision. Minimal dissection around the aorta and the right atrium is performed to allow cannulation for cardiopulmonary bypass (CPB) and aortic cross-clamp placement.

The exposure of femoral artery (or alternatively the axillary artery) for CPB access is the safer approach, but it is not free from potential complications [13, 21]. In addition, based on the principle that antegrade perfusion has advantages over retrograde flow, [22, 23] it is better to adopt total central (aortic) cannulation, whenever possible. Under direct visualisation, the aorta is exposed up to the origin of the innominate artery after which two concentric purse string sutures for direct arterial cannulation are placed in a standard fashion. The cannulation site is generally chosen by identifying the transverse sinus as the orientation where the aortic cross-clamp will be placed. It is advisable that cannulation site is at some distance above the crossclamp level. Ascending aorta cannulation is performed under direct vision as routinely.

Venous drainage is achieved through the right atrium. The left ventricle is vented through the right upper pulmonary vein. Continuous carbon dioxide insufflation is used during the operation at a flow of 2 litres/minute. The ascending aorta is cross-clamped at the origin of the innominate artery and hypothermic 4°C blood cardioplegia (St Thomas with procaine) is administered in an antegrade fashion into the aortic root to stop the heart and then directly into the coronary ostia in case of aortic regurgitation.

Figure 1.

Myocardial protection is crucial, especially in patients undergoing AVR who have undergone previous coronary artery bypass graft surgery (CABG) and a patent left internal mammary graft (LIMA). Usually temporary occlusion of LIMA pedicle is adopted during

cardioplegic arrest to avoid myocardial regional warming and cardioplegic solution “washout.” Nevertheless, sometimes, the isolation of LIMA is not easy as it may be difficult to access and there is risk of LIMA injury. For these reasons, it is possible to maintain LIMA unclamped and to adopt a blood normothermic antegrade repeated each 20 minutes. The aim of the initial dose of cardioplegia is to arrest the heart to open the aorta and to explore the aortic valve; if the heart restarts to contract the main goal is to keep the left heart well vented without cooling down the patient. Our results, in addition to data from the literature, do not show an increased incidence in perioperative morbidity and mortality in the case of an unclamped LIMA graft [17, 20, 24]. In 1999, Byrne and colleagues left the LIMA graft unclamped while performing the AVR under hypothermia (20°C) and cardioplegic arrest [15]. Kaneko proposed to cool the patients to 25°C to 30°C and to adopt both antegrade and retrograde cardioplegia. When cardiac activity was observed because of a patent LIMA graft, additional systemic potassium was given through the pump (40 mEq) to a dosage of 6.0 to 7.0 mEq [18, 19].

A transverse incision of the ascending aorta is performed and the native valve is excised. The prosthetic valve is implanted using three running 2-0 (120 cm long) polypropylene sutures as we do routinely in conventional AVRs (Fig 1). Ascending aorta incision is closed using a 4-0 double suture.

The ventricular pacing wire must be placed on the right ventricle when aorta is still clamped and the heart is still and empty. Sometimes, this manoeuvre can be challenging due to the adhesions and the limited surgical field. In this case, temporary endocardial pacing leads through the right internal jugular vein can be placed [17-19].

Deairing the heart is achieved using a 2-stage procedure. First, the table is lifted head up, the heart is filled, both lungs are ventilated, and air is removed from the left atrium through the vent. The bed is then placed head down, the aortic clamp is released, and air is removed via the transmitral vent and the aortic vent. In addition, correct de-airing is ensured with continuous carbon dioxide insufflation and trans-oesophageal echocardiography is always used to monitor it and to assess prosthesis function [17-19]. The patient is then weaned from CPB. Cannulae are removed and protamine is administered at a 1:1 ratio with heparin. Sternum is closed with steel wires and subcutaneous sutures are employed for wound closure.

RESULTS

Between October 2007 and October 2015, a total of 2788 consecutive adult patients underwent isolated AVR at our institution. This included 153 patients who had had previously undergone previous cardiac surgery. In this chapter, we present the results of 59 patients in whom UHS approach was chosen instead of conventional full sternotomy, which was employed in the remaining 94 patients.

Patients' demographic and operative data are expressed as mean $\pm$ standard deviation, medians (interquartile range, IQR, 25th-75th percentiles) or as prevalence percentages, as appropriate. All statistical analysis was performed with SPSS software, version 23.0 (SPSS Inc, Chicago, IL, USA).

Table 1. Baseline characteristics of the patients

Age (years)	75 (66-78)
Male sex	35 (59.3%)
Hypertension	49 (83.1%)
Diabetes	14 (23.7%)
Smoking status	
Current	12 (20.3%)
Former	14 (23.8%)
Chronic lung disease	11 (18.3%)
Atrial fibrillation	12 (20.3%)
Ejection fraction (%)	55 (48-60)
Prior Coronary Artery Bypass graft	31 (52.5%)
Euro SCORE ♦	10 (8-12)

Counts are presented as number of patients and percentage of total series. Continuous data are presented as median (25 percentile to 75 percentile).

♦ EuroSCORE= European system for cardiac operative risk evaluation.

Table 2. Early postoperative outcome

Tracheostomy	3 (5.1%)
Sepsis	1 (1.7%)
Re-exploration for bleeding	5 (8.5%)
Post-operative Pacemaker	5 (8.5%)
Atrial fibrillation	11 (18.6%)
Blood transfusions	41 (69.5%)
Red blood cell units	2 (1.7-5)
Ventilation time (hours)	6.5 (5-13.3)
Intensive Care Unit stay (hours)	47.5 (38-72)
Discharged alive	58 (98.3%)

Counts are presented as number of patients and percentage of total series. Continuous data are presented as median (25 percentile to 75 percentile).

The median age of patients was 75 years (interquartile range (IR): 66-78 years) and 35 were male (59.3%). Previous cardiac surgery procedures included CABG in 31 pts (2 had LIMA-right internal mammary graft patent “Y” grafts). Demographic, intraoperative and short-term outcome data of all patients were collected and analysed. Patients baseline characteristics are described in Table 1. Overall median CPB time was 65 minutes (IR 55-79 minutes) and median aortic cross clamp time was 49 minutes (IR 42-64 minutes). In 44 patients (74.5%), a biological prosthesis was implanted because of the patient’s age or preference; in the remaining 15 patients, a mechanical valve was used. Median intensive care and hospital stay were 47.5 hours (IR: 38-72 hours) and 8 days (IR: 7-11days), respectively. Hospital mortality was 1.7% (1/59). All postoperative outcomes are reported in Table 2.

CONCLUSION

We believe that, in contrast to some already described disadvantages, the minimally invasive surgical option offers various benefits. Firstly, it reduces surgical trauma due to

lesser dissection of pericardial adhesions and the mediastinal dissection is limited to the ascending aorta and a small portion of the right atrium. The right ventricle does not need to be dissected completely. This avoids bleeding and risk of injury, especially in cases of patent bypass grafts [26-27]. The UHS for MlR AVR offers an adequate surgical and aortic valve exposure and an easy conversion to full sternotomy if required. The minimally invasive alternative approach is the ART [28], but this is more technically challenging in re-operative cases. Secondly, the aesthetic result is worst due to the presence of a second scar in the thorax.

The available data suggests a favourable effect of MlR AVR without compromising the efficacy of the entire operative procedure. The reported operative mortality and morbidity figures are very encouraging [11, 14, 18, 20, 29-31], despite including results from the surgeons' learning curve. The authors of this chapter believe that MlR AVR reduces biological invasiveness, which may result into shorter duration of surgery, hospital stay and lower risk for sternal instability and/or infection.

Chapter 405

TOTALLY ENDOSCOPIC AND ROBOTICALLY- ENHANCED MINIMALLY INVASIVE AORTIC VALVE SURGERY

Marco Vola, MD, PhD and Antoine Gerbay*, MD

Department of Cardiovascular Surgery
University Hospital of Saint-Etienne Saint-Etienne, France

ABSTRACT

Totally endoscopic aortic valve replacement (TEAVR) is not opposed but complementary to trans-catheter aortic valve replacement, since as a surgical therapy TEAVR still provides the removal of the underlying pathology prior to the insertion of a valvular substitute. TEAVR could become the surgical approach of reference in terms of early recovery post-aortic valve replacement. The approach has proven to be feasible with use of the sutureless prostheses. It is our challenge to safely increase the procedural reproducibility.

Keywords: endoscopic, minimal, aortic, valve, robotic

INTRODUCTION

Several minimally invasive approaches have already proven to provide advantages over full sternotomy in terms of blood transfusion and reduction of postoperative discomfort. Totally endoscopic cardiac surgery has showed excellent results in terms of post-operative life quality [1, 2]. The perspective to perform surgical aortic valve replacement (AVR) in a closed chest setting also is our forthcoming challenge.

* Corresponding Author: Antoine Gerbay MD Department of Cardiovascular Surgery, University Hospital of Saint-Etienne, Saint-Etienne, France.

RATIONALE OF TOTALLY ENDOSCOPIC AORTIC VALVE SURGERY

Totally endoscopic aortic valve replacement (TEAVR) aims maximal reduction of surgical wall chest trauma necessary for a biologic AVR. However, such technical effort may question part of the scientific community, since trans-catheter aortic valve replacement (TAVR) with reported excellent results of third generation devices, could be soon extended into lower risk patients. On the other hand, surgery facilitates the removal of calcified aortic valvular tissues, that contribute to a considerable incidence to transcatheter paravalvular regurgitation responsible, for the reported lower 5 year life expectancy [3] after TAVR. The asymmetric distribution of aortic valve calcifications contributes to the elliptic expansion of transcatheter stents, with an asymmetric leaflet valve opening and a supposed lower prosthetic durability. Finally, the role of a delayed chronic micro embolisation, from the aortic anfractuous calcified tissues acting as a nidus for micro thrombi, is actually under investigation [4]. These elements, associated with a fairly high incidence of pace maker implantation in some third generation TAVR models (e.g., the Sapien III, [5]), fuels ongoing discussion to invest energy in the refinement of an evolved surgical setting aimed primarily at intermediate and low risk patients with a high calcium score. The objective is to provide the removal of calcium before the implantation of a valvular substitute, an extremely low grade of invasiveness and an improved quality of life. Moreover, intermediate risk patients compared to high risk aged patients can tolerate longer cross clamp times and benefit from a quick return to an active lifestyle. These are the patients who are the ideal target for TEAVR.

The widely available stented valves are incompressible and still need a mini-thoracotomy to be inserted into the thorax since they cannot be compressed into trocars. But with the introduction of sutureless Nitinol stented prosthesis, this issue was resolved, and the first human totally endoscopic valve replacement was performed in 2013 [6].

COMPRESSIBLE SUTURELESS VALVES AS A CONDITION FOR A TOTALLY ENDOSCOPIC APPROACH

The primary aim of sutureless bioprosthesis is to avoid the passage of stitches into the aortic annulus and knot-tying. Several reports [7-10] are focused on the ischaemic time that is supposed to be saved with this technology. Nevertheless, it appears that the reduction of the cross-clamp time, as compared to the sutured valves, is less marked in the full sternotomy procedures as compared to minimally invasive. This is true, especially with the anterior right mini-thoracotomy, which is more challenging than its upper hemi-sternotomy counterpart [11]. Beyond this time-saving logic, there is a technical advantage in use of sutureless valves. This is the avoidance of sutures in settings where their placement is technically challenging or impossible (e.g., hypercalcified aortic roots, re-operative aortic stentless valve procedures, etc. [12-15]).

Concerning the totally endoscopic approach, a further property of the Nitinol sutureless valves becomes pivotal: the possibility to fold/compress the bioprostheses in order to introduce them into a thoracoscopic trocar. Since the existing commercially available thoracoscopic largest trocars measure 20mm (internal diameter), it is mandatory that all sizes

of sutureless valves selected for the endoscopic approach can be reduced at this diameter when folded, before the re-expansion into the aortic root. These compression ratios have been studied for the 3f Enable and Perceval sutureless models, that both fulfill the criterion [16]. But it not excluded that, in the future, second generation sutureless valve would not be able to fit into lower diameter trocars. In fact, the industry is actually moving towards a common valve which could be adaptable into a Nitinol stented sutureless like valve when surgical decalcification is indicated prior to implantation or into a TAVR like valve, if decalcification is not needed and a simple implantation of a prosthesis is sufficient.

SURGICAL SET-UP

The procedure is performed under selective pulmonary ventilation. Purse strings are placed onto the common femoral artery and vein in order to establish femoro-femoral bypass. Cardio-protection is performed with Custodiol solution (histidine-tryptophanketoglutarate cardioplegic solution; Kohler Chemie, Alsbach-Hahnlein, Germany). The main working trocar (20mm, Flexipath; Ethicon, Inc, Somerville, NJ) is placed in the second intercostal space, a second operative trocar (15mm) is in the third, a percutaneous transthoracic aortic clamp is in the first, a 5-mm30 optic is in the second (7mm trocar), and a right pulmonary vein venting line and purse-string with carbon dioxide insufflation line are in the fifth (with a 7mm trocar) Figure 1). A complete video of the procedure with use of the 3f Enable valve is available at the following link: <http://www.annalscts.com/article/view/4990/6716>).

Figure 1. Operative setting. The aorta is cross clamped (Chitwood clamp, first intercostal space). Note the vent and the corresponding purse string throughout the trocar in the fifth space.

PATIENT SELECTION

Patients should be selected considering that TEAVR is a procedure in phase of clinical development, with longer cross clamping times as compared to open surgery: thus it is reasonable to avoid patients with significant ventricular or renal dysfunction. Moreover,

patients have to fulfill criteria for safe retrograde cardio-pulmonary bypass. It is recommended to avoid patients with insufficient peri-aortic working space (<2 cm between the inferior margin of the sternum and the aortic anterior wall). To keep comfortable distance between the aortic clamp, the cardioplegia needle, and the aortotomy, and consequently safe placement of the aortic closing sutures, very short aortas should also be excluded (the central line of the ascending aorta should be longer than 5 cm). Vertical aortas without physiologic curvature should be avoided. The central axis of the proximal aortic root together with the operative axis of the third intercostal space should be ascertained. A CT scan is performed to assess these anatomic criteria. A 3D reconstruction can be helpful in planning the ideal position of the trocars for each patient (Figure 2).

Figure 2. CT scan 3D reconstruction. (A) trocar position planning in consideration of the aortic root anatomy; (B) Cutaneous projection of the same trocar position in order to simulate the localisation of the patient's micro-incisions on the skin.

MANAGEMENT OF THE SUTURELESS VALVE INTO THE AORTIC ROOT

The 3f Enable valve, now withdrawn from the market, was the first model implanted experimentally (cadaver) and clinically in a totally endoscopic setting. This prosthesis is manually folded and is not provided with a real holder but just with a simple grasper keeping the stent folded. But once descended into the thorax immediately after the passage into the trocar, the lower part of the stent tended to expand making further approach into the aortic root problematic. Thus the technique of implantation was modified, adding two 4/0 prolene stitches sutured one at the flange and one higher, at the level of the Nitinol stent. This ensured that the prosthesis remained collapsed and facilitated control, by cutting the stitches when the flange was perfectly aligned with the native annulus (Figure 3).

The Perceval is managed with a holder that keeps the valve folded. Moreover, the release of the prosthesis is performed with three guiding sutures facilitating the alignment of the prosthetic flange with the native annulus. The implantation of the Perceval prosthesis has already reported to be safe and reproducible via a mini-thoracotomy [11]. In our recent clinical experience it was shown that it was implantable throughout a 20 mm trocar within cross clamp times lower than the mean value of our previous 3f Enable TEAVR experience (112 ± 18 minutes, 14 patients). In the Perceval TEAVR approach, use of three tourniquets preventing any prolene twist around the holder has been necessary (Figure 4), but the rest of the implantation technique is not different as compared to open access.

Figure 3. A. 3f Enable valve kept folded by a prolene stitch at the flange. B: Cutting of the prolene stitch end valve expansion (C and D).

Figure 4. Perceval TEAVR: note the use of tourniquets that will follow the descent of the valve into the aortic root in order to facilitate the management of the guiding suture.

CHALLENGES AND PERSPECTIVES

Robotic Assisted Aortic Valve Replacement via a Right Minithoracotomy

Use of the da Vinci tele manipulation system is reported by several authors in mitral repair and replacement [17, 18]. Concerning aortic valve surgery, few robotic assisted procedures via a right mini-thoracotomy have been published by Folliguet and colleagues [19]: 10 patients were successfully operated on with 98.2 ± 30.4 min of cross clamp time. Two robotic arms were placed, one in the second intercostal space mid axillary and one in the fifth or fourth intercostal. In 2010, Suri and collaborators reported, in a cadaveric study [20], the replacement of the aortic valve with the sutureless Perceval prosthesis through a 4cm right mini-thoracotomy.

Robotic TEAVR

No clinical reports have been published with a totally thoracoscopic procedure, as intended exclusively through thoracoscopic trocars.

Figure 5. A) Robotic Perceval TEAVR (Da Vinci Robot, Cadaveric study). B) endoscopic sizing with use of the Vola endoscopic sizer.

Some technical reasons may explain the poverty of application of the robotic surgery in the aortic valve field as compared to the mitral. As per the non-robotic totally endoscopic approach, the ideal setting of the operating arms, with use of the actual sutureless Nitinol stented valves (the Perceval), must be adapted to operate in the aortic root in consideration of a high aortotomy. In fact, during the aortotomy, sufficient margin of aortic tissue should remain at the proximal aortic margin, from the Nitinol stent, in order to enable a safe and quick closure. It follows that the aortic root is a more difficult working space as compared to the left atrium. Specifically, the discardment between the robotic arms is reduced, and the triangulation between the optics and the two operative arms is also very limited. In a cadaveric report of totally endoscopic aortic valve replacement with the da Vinci System Si (Intuitive Surgical, Sunnyvale, CA, USA) model conducted by our group and implantation either of the 3F Enable and Perceval sutureless prostheses [21] (Figure 5), the arms had to be specifically adapted to avoid any conflict. The Surgical setting adopted in this report included positioning of a 20mm main working port into the second intercostal space for the introduction of the valve into the thorax; a second working port is positioned into the first intercostal space (left robotic arm), a second robotic arm in the third or fourth intercostal space (right robotic arm). Laterally (anterior axillary line) optics (30°) are positioned in the second intercostal space, and a transthoracic percutaneous clamp (Chitwood clamp) in the first intercostal space. The new model of the Da Vinci Xi telemanipulator (Intuitive Surgical, Sunnyvale, CA, USA) could be of interest for this aortic valve application since the arms are thinner and the conflict external to the thorax can be reduced. Experimental studies in this area are still awaited.

Figure 6. A-D. Progressive expansion of the plastic tape at the extremity of the Vola's endoscopic expandable sizer.

Robot advantages in sutureless TEAVR are potentially focused on the native calcified aortic valve removal and the ascending aorta closure. On the other hand, no cadaveric studies have been conducted in presence of selected calcified or heavily calcified leaflets.

Additionally, the actual surgical instruments of the da Vinci system are not conceived specifically to decalcify a stenotic aortic valve apparatus. The da Vinci system could also be helpful in enhancing the reproducibility of the running suture of the ascending aorta. Nevertheless, the lack of tactile feedback has to be taken in account when tissues are fragile.

Endoscopic Sizing

Although in our previous TEAVR experience with in the 3F Enable valve, annular sizing was image-based, physical annular sizing remains fundamental in current and future use of sutureless valves. Unless the skin of the main trocar cutaneous incision is stretched, passage of Perceval sizers greater than the “small” one is actually impossible throughout that limited incision (20mm length). The problem can be overcome only with the development of dedicated endoscopic expandable sizers (Figure 5b and 6). These devices are not yet CE marked and will be clinically tested with an institutional pilot study.

Venous Percutaneous Retrograde Cardioplegia and Endoventing

Pulmonary vein venting requires the preparation of purse string that requires careful surgical training. The future solution seems to be interestingly overcome by using a trans-jugular pulmonary artery vent. Only one device labelled for this use is actually available (Edwards Endovent (Edwards, Irvine CA) and further literature is awaited in this area. More generally, in a closed-chest context, the trans-jugular access also seems promising for the insertion of trans-jugular pacing catheter and retrograde cardioplegia delivery.

CONCLUSION

Overall, the TEAVR development process should lead to a four step “closed chest” rapid and reproducible procedure: this is an ambitious target needing further technical development. The affirmation of such a technique as a surgical reference in the future will be function of the capacity to set a device-assisted procedure rather than investing in a very intensive endoscopic training enabling only highly specialised surgeons and high volume centers. Ideally, this latter condition may be acceptable only in a transitional phase of the technique, as it is at present.

Chapter 406

RAPID DEPLOYMENT AORTIC VALVES AND MINIMALLY INVASIVE SURGERY

Kevin Phan and Tristan D. Yan*, MD, PhD

University of Sydney, Sydney Adventist Hospital, Sydney, NSW, Australia
University of Sydney, Royal Prince Alfred Hospital,
Sydney, Australia

ABSTRACT

Early clinical evidence suggests that the sutureless aortic valve prosthesis is suitable for both traditional and minimally invasive approaches to minimize cross-clamp and bypass time, which may reduce perioperative risk. This chapter will overview the history, rational, current evidence and future directions for sutureless or rapid deployment aortic prostheses.

Keywords: rapid deployment, aortic valve, minimally invasive

INTRODUCTION

Aortic stenosis (AS) is the most frequent type of valvular cardiac disease [1]. With increasing prevalence in elderly population more than 65 years, clinicians are frequently facing the challenging of treating or managing elderly patients with complex cardiac comorbidities and advanced valvular disease [2]. Particularly in a burgeoning era of increased healthcare costs, there is a continued need to re-evaluate surgical procedures and interventions performed in this population, whether such interventions are justified, and how can patients and procedures be selected to achieve optimal patient outcomes and associated costs. In the context of cardiac surgery, in recent decades there has been a massive emphasis on minimally invasive surgical techniques, to minimize the burden of surgical trauma to the

* Corresponding Author's Email: tristanyan@annalscts.com.

patient. Such strategies have aimed at reducing incision sizes, reducing cardio-pulmonary bypass (CPB) [3, 4] and cross-clamp times (AoX) [5], and the use of percutaneous catheter based technologies [6, 7].

Aortic valvular surgery is still undergoing a transformation from a traditional open approach to minimally invasive approaches. The traditional approach for aortic valve stenosis was an aortic valve replacement (AVR) via median sternotomy, with implantation using either a biological or mechanical prosthesis. There are many follow-up studies which have demonstrated safe and long-term efficacy for the standard AVR for AS treatment. Following this, minimally invasive aortic valve replacement (MIAVR) was introduced to minimize surgical trauma [4, 8, 9]. To further improve an effective treatment, the focus has shifted to minimising the invasiveness of the procedure and to expand the boundaries of operability to elderly patients who are at higher surgical risk with multiple comorbidities.

Transcatheter aortic valve replacement (TAVR) via a transfemoral or transapical approach has emerged in the past 10 years as an alternative to sternotomy and extracorporeal circulation as well as ischemia associated with aortic cross-clamping [6, 7, 10, 11]. TAVR has expanded the realm of interventions to carefully selected high risk inoperable elderly patients. Despite tremendous implications of this technology, ultimately the diseased native valve is left in place, resulting in drawbacks including paravalvular leak, increased pacemaker requirements, and the potential for strokes, vascular complications and implant migration [10]. Furthermore, the TAVR prosthesis is based on a crimping technique, which may affect the durability of the TAVR prosthesis [12]. As such, whilst TAVR produces an excellent opportunity to replace the valve in high-risk or inoperable patients, there is no definitive evidence supporting the use of TAVR for patients in the “intermediate grey zone” of intermediate to high-risk operability.

The natural progression of technological advancement have led to the development of an approach which may indicated specifically for such patients in the “intermediate” range – the progression from conventional “sutured” valves to “sutureless” or rapid deployed aortic valves. Modern sutureless aortic valves have been introduced and used in practice since early 2007 in Europe and 2009 in North America. This technology avoids or minimizes the requirement for placement and tying of sutures following annular decalcification, and can revolutionize AVR by reducing cross-clamp and cardiopulmonary bypass durations as well as facilitate minimally invasive approaches. Overall, this has the potential to reduce postoperative mortality, morbidity, postoperative stay, and improve cost-effectiveness. Furthermore in contrast to transcatheter techniques, sutureless AVR may offer a “curative” procedure since the native diseased valve is excised.

Early clinical evidence suggests that the sutureless aortic prosthesis is suitable for both traditional and minimally invasive approaches to minimize AoX and CPB time, which may reduce perioperative risk.

This chapter will overview the history, rational, current evidence and future directions for sutureless or rapid deployment aortic prostheses.

HISTORY OF SUTURELESS VALVES

Despite the recent focus on sutureless technology on the latter half of the past decade, the concept was first introduced in the early 1960s. The earliest model of sutureless valve fixation

was developed by Magovern and Cromie [13]. This consisted of a valve Belfixation ring combined with mechanical ball-cage aortic valve prosthesis. There were two mechanisms of valve replacement that was developed: (1) circular base with upper and lower plates, and 9 L-shaped pins which eject laterally and driven into the aortic wall for fixation; and (2) central cylinder with grooved surface, with 2 rings threaded and 24 curve pins to eject laterally and fixate on the aortic wall. The purported advantages of their design was that it could be implanted faster and had an increased valvular diameter and aortic valve area when compared to equal sized conventional valves.

The first Magovern-Cromie valve was implanted in 1962, and Magovern continued to implant this valve for several more years. In their initial cohort study which included 7 aortic and 3 mitral sutureless implantations by Magovern, the mean AoX time was 30 minutes [13]. From 10 patients, there was 3 hospital deaths and 1 late death caused by cerebral embolism. Data from a further 52 patients of the same group and prosthesis demonstrated an AoX time of 18 minutes, however, this was offset by increased complications of thromboembolism, ball variance, paravalvular leak, endocarditis and insufficient anticoagulation [14]. Magovern did note that many pitfalls of the procedure could be minimised by changing the design of the valve. He also stated that none of the hospital deaths within the aortic patients were likely related to common issues in cardiac surgery such as renal failure, bleeding, arrhythmias, pulmonary emboli or endocarditis. Over 7300 Magovern-Cromie prostheses were implanted, however, production ceased in 1980 [15]. However, the initial sutureless prosthesis remains a significant milestone in cardiac surgery which was way ahead of its time, with the first valve implantation performed by Harken only two years previously [16].

After this period, the concept of sutureless implantation of valvular prostheses was forgotten, whilst transcatheter based technologies started to develop and flourish. The percutaneous technique was first introduced via the concept of balloon valvuloplasty, introduced in 1985. Alain Cribier performed the first percutaneous valve implantation in 2002 [17], based on the concept of mounting a biological aortic valve into a metal or Nitinol stent, compressing it into a catheter and balloon the Nitinol-stent based valve into position. Whilst the percutaneous approach was initially performed via transfemoral access, in patients presenting with severe peripheral vascular disease, the transapical approach represented an alternative option. These developments have spurred the resurgence of sutureless technology in the surgical community, as a surgical alternative to TAVR in high risk operable patients. There are currently three sutureless prostheses that have been approved (Figure1): (A) 3F Enable (Medtronic, Minneapolis, USA); (B) Perceval S (Sorin, Saluggia, Italy); (C) Intuity (Edward Lifesciences, Irvine, USA).

There are several similarities and differences between sutureless/rapid deployment aortic valves and transcatheter prostheses. Whilst sutureless prostheses are based on a similar technology and concept to TAVR prostheses, the sutureless approach does not require crimping of the pericardium. The sutureless surgical approach allows direct visualization of the diseased native valve and target orifice, and facilitates removal of the diseased valve and annulus calcification prior to deployment of the replacement prosthesis. In contrast, TAVR relies on visualization of the prosthesis and deployment indirectly via fluoroscopy. Current TAVR protocols do not involve removal of the native diseased valve, which in some cases is responsible for post-operative paravalvular leak. In comparison with standard conventional AVR, sutureless valves do not require extensive placement or tying of sutures. Both

procedures involve excision of the diseased valve, require CPB and AoX. Both procedures can be approached using standard median sternotomy, ministernotomy or minithoracotomy.

Figure 1. Commercially available sutureless aortic valves. (A) 3F Enable (Medtronic, Minneapolis, USA); (B) Perceval S (Sorin, Saluggia, Italy); (C) Intuity Elite (Edward Lifesciences, Irvine, USA).

TYPES OF RAPID DEPLOYMENT AORTIC VALVES

The 3F Enable Sutureless aortic valve, CE mark approved in 2009, was designed to mimic the function of the native valve. It consists of the 3F aortic bioprosthesis model 1000 assembled from three equal sections of equine pericardial material, fixed with glutaraldehyde and mounted on a self-expanding Nitinol frame. A polyester fabric covers the inflow flange/skirt. The expanding Nitinol frame allows fixation of the device in the native annulus via outward radial forces. The first implantation was in 2005 on a 76-year old male by Sadowski. Early results were promising, with deployment time of 148 ± 173 seconds and cross-clamp time of 55 minutes. Postoperatively, the mean aortic valve area was 3.18 ± 0.41 cm². However, mild paravalvular leak was detected and attributed to insufficient nitinol-based stent radial forces. In 2006, an expanded valve cuff was added to the 3F Enable design as well as a change to a double flange design, in an effort to reduce paravalvular leak.

Implantation of the 3F Enable valve can be performed under full sternotomy or ministernotomy. Standard CPB is established by cannulation of the ascending aorta and right atrium. As per conventional AVR, transverse aortotomy is performed, with the native diseased valve excised and annulus decalcified. Particularly for sutureless valves, the sizing of the prosthesis is crucial – it is not possible to expand an oversized Enable valve in a smaller annulus. The advantage of the nitinol frame and flexibility of the pericardial leaflets is that the device can be folded in chilled water intraoperatively and positioned in the root. After deployment, the Nitinol stent shape and size return to preset dimensions. Its inherent outward radial forces will allow fixation of the position. Whilst no sutures are required for implantation, it is recommended that two permanent sutures put in to support the prosthesis at the annulus.

The Perceval sutureless valve was CE approved in 2011. This prosthesis consists of bovine pericardium tissue attached of self-expandable elastic Ni-Ti alloy stent made of two rings and nine vertical struts, with the dual task of supporting the valve and holding it in place without any permanent suture. It also has a thin coating of Carbofilm™ to improve biocompatibility. For implantation, the valve is collapsed with an atraumatic device. The

valve remains collapsed until it is positioned correctly, which enables direct visualization. Once in the appropriate position, it can be self-expanded back to its original diameter.

The design of the Edwards Intuity valve, CE approved in 2012, is based on the Perimount valve family. The Edwards Intuity valve is a stented trileaflet bovine pericardial bioprosthesis, with a balloon-expandable, cloth-covered skirt frame at the inflow aspect. For implantation, three equidistant guiding sutures are placed through the annulus at the nadir of each sinus. This is then passed through corresponding black marks on the nadir portion of the valve suture ring. These three set of guide sutures are used to position the valve in the aortic annulus. The balloon-expandable frame is then deployed via short balloon inflation, followed by tying of the guide sutures.

RATIONALE

The introduction of sutureless or rapid deployment aortic valves has the potential to revolutionize minimally invasive aortic valve surgery. First from a technical perspective, sutureless AVR involves excision and removal of the native diseased valve – a curative approach – which contrasts with current TAVR procedures where the diseased native valve is not removed. The main advantage offered by these technologies is a reduction in AoX and CPB duration, given that there is easier placement and less tying of sutures required [18]. In the context of the cardiothoracic surgical literature, extended AoX and CPB durations have been linked with cardiovascular morbidity [19]. Particularly in patients with poorer left ventricular ejection fraction or with diabetes, a reduction in AoX or CPB duration has the potential to decrease complications risk and long-term mortality, even in the face of the most modern cardio-protective techniques and methods.

A systematic review and meta-analysis conducted by the International Valvular Surgery Study Group (IVSSG) identified 12 studies, which when pooled showed a pooled AoX and CPB duration for isolated AVR using a sutureless prosthesis of 56.7 and 33 min, respectively, half of that compared to values reported by the Society of Thoracic Surgeons (STS) National Database for conventional sutured AVR. Cross-clamp times in minimally invasive surgery were comparable to full sternotomy. Thus, the reduction of AoX and CPB time with sutureless or rapid deployment aortic valves may improve results in all patients, but may particularly be beneficial in patients with significant underlying comorbidities and high surgical risk profiles. As such, the sutureless approach may also be reasonable in complex operations with multiple interventions, to reduce operative duration and improve outcomes.

Another advantage of sutureless technology is its potential to facilitate minimally invasive aortic valve surgery. Prior studies have demonstrated similar outcomes between MIAVR and conventional AVR, including decreased hospital stay, reduced sternal wound complications, surgical trauma and improved cosmesis. However, the MIAVR approach also has its limitations including a difficult learning curve, longer AoX and CPB durations, which has limited its dissemination into the wide cardiothoracic community. The technical difficulty and longer durations involved is partly due to the challenging placement and tying of sutureless down a narrow surgical corridor. As such, the use of rapid deployment technology can help overcome this barrier, by simplifying the MIAVR procedure and avoiding the need to suture the aortic valve to the annulus via this limited surgical field. With reduced operation

complexity and duration, the use of sutureless prostheses in the setting of mini access surgery may facilitated further improvements in outcomes, as well as facilitate this operation in more elderly and higher risk operable patients.

Sutureless prostheses may also be more superior to its transcatheter counterpart by means of paravalvular leak rates. Paravalvular leak has been previously associated with poorer outcomes following TAVR, predicting 1-year mortality even after multivariate adjustment in a meta-analysis by Athappan et al. Paravalvular leak rates are expected to be lower in sutureless AVR. From a procedural standpoint, sutureless AVR involves excision of the calcified valve and prosthesis under direct visualization, with pooled leak rates of 2-4% at latest follow-up. This is significantly lower than reported rates of 12% following TAVR.

Additionally, sutureless AVR is associated with excellent hemodynamic outcomes, with very low transvalvular gradients and reduced risk of patient-prosthesis mismatch (PPM). As such, high risk subset patients will more likely than others to benefit from sutureless AVR, a promising alternative with excellent hemodynamic performance that facilitates minimally invasive and less traumatic approaches while minimizing CPB and AoX durations.

INDICATIONS

Currently, the indications and contraindications for sutureless and rapid deployment aortic prostheses follow the recommendations and guidelines for biological stented aortic prostheses [2, 20]. Since current recommendations suggest patients 65 years and older to be potential candidates for biological valve replacement, it is also recommended to consider sutureless and rapid deployment valves for patients of the same age group. Sutureless and rapid deployment valves may be a suitable alternative to stented valves in isolated procedures in patients with comorbidities, delicate aortic wall conditions as calcified root, porcelain aorta or prior implantation of aortic homograft and stentless valves as well as for concomitant procedures and small aortic roots.

For concomitant procedures, sutureless valves may be considered as the prosthesis of first choice to reduce complications and morbidity associated with the duration of extracorporeal circulation and cross-clamp time [20-23]. For reoperative procedures, there may be extensive adhesions which could distort cardiac structures. As such, limited access surgery may be difficult and challenging [24-26]. In this setting, sutureless and rapid deployment valves may facilitate redo operations due to prior AVR, coronary artery bypass grafting (CABG) or delicate aortic wall conditions as calcified root and porcelain aorta [27, 28].

In terms of annulus size, 19 mm is considered too small for the implantation of sutureless and rapid deployment valves. Annulus enlargement procedures would be necessary, due to size limits of the current available prostheses. However, since these procedures may be time-consuming and the implantation of patch material in the aortic annulus may result in less stability to anchor a self-expanding valve. It is recommended that root enlargement procedures should be avoided if sutureless or rapid deployment valves are considered [29]. The use of sutureless and rapid deployment valves is currently limited to annular sizes of 19–27 mm [29].

DISCUSSION AND CLINICAL EVIDENCE

Several systematic reviews and meta-analyses have explored outcomes of sutureless aortic valve surgery [18, 30, 31]. From 12 studies identified for inclusion, the minimally invasive approach was used in 40.4% of included patients, while 22.8% underwent concomitant CABG. Pooled AoX and CPB duration for isolated AVR was 56.7 and 46.5 minutes, respectively. Pooled 30-day and 1-year mortality rates were 2.1% and 4.9%, respectively, while the incidences of strokes (1.5%), valve degenerations (0.4%) and paravalvular leaks (PVL) (3.0%) were acceptable. The authors concluded that sutureless aortic valve implantation is a safe procedure associated with shorter AoX and CPB duration.

Sutureless vs Conventional Aortic Valve Replacement

There have been several comparative studies investigating outcomes of sutureless versus conventional AVR. In 2013, D'Onofrio et al. [32, 33] reported a comparison between conventional surgery, sutureless valves and transapical TAVR for AVR. From 2009-2012, 566 TAVR, 349 AVR and 38 sutureless AVR patients were treated. There was 0 deaths in the sutureless AVR group compared to 1 death in the AVR group. There were no strokes in either group, both groups had one case each of permanent pacemaker required. There were 6 cases (19.4%) of postoperative aortic regurgitation (AR) in the sutureless AVR group compared to 2 cases (1.8%) in the AVR group. After matching and multivariate analysis, there were no differences between the groups in terms of postoperative outcomes. The authors concluded that similar outcomes were achieved with matched sutureless and conventional AVR surgery.

Shrestha et al. [34] compared 70 AVRs versus 50 sutureless AVR elderly patients >75 years old with small aortic roots (<22 mm). The sutureless technique was associated with shorter CPB time (58.7 vs 75.3 minutes) and AoX time (30.1 vs 50.3 minutes). There were 3 deaths (4.3%) in the conventional group versus no deaths in the sutureless group. The authors concluded that sutureless surgery may be advantageous by facilitating minimally invasive surgery in elderly patients with small aortic roots.

In the first randomized study comparing minimally invasive rapid deployment versus conventional AVR, Borger et al. [5] demonstrated that the sutureless approach involved significantly reduced AoX times (41.3 vs 54 minutes) but similar CPB times (68.8 vs 74.4 minutes). There were also similar early clinical outcomes. The sutureless approach was associated with lower mean transvalvular gradients (8.5 vs 10.3 mmHg) and lower patient-prosthesis mismatch (0 vs 15%). The authors concluded that rapid deployment aortic prosthesis may result in reduced AoX time and improved valvular hemodynamics in comparison to conventional stented bioprostheses.

Similar conclusions were reached by Dalen et al. [35], who matched 133 conventional AVR and 133 sutureless AVR patients. The sutureless approach was associated with significantly reduced CPB and AoX times. Similar in-hospital mortality was reported for the two groups, similar incidence of postoperative strokes and pacemaker implantations, but shorter duration of mechanical ventilation was required in the sutureless group. Despite the limits of its retrospective design, the study confirms that sutureless AVR significantly reduces operative and mechanically assisted ventilation times compared with sutured prostheses, and

is associated with low mortality and morbidity, leading to excellent surgical and hemodynamic results.

Several systematic reviews and meta-analyses have explored outcomes between sutureless and conventional AVR as well as sutureless and TAVR. Hurley et al. [30] performed a meta-analysis to compare outcomes of 832 sutureless patients versus 3740 conventional AVR patients. AoX (39.8 vs 62.4 minutes; $P < 0.001$) and CPB (64.9 vs 86.7 minutes) times were shorter in the sutureless group. Permanent pacemaker implantation rate was higher in the sutureless cohort (9.1% vs 2.4%).

Sutureless vs Transcatheter Aortic Valve Replacement

Santarpino et al. [36] studied 37 matched pairs of patients who underwent TAVR and sutureless AVR. Preoperative characteristics and risk scores were comparable. The authors found that permanent pacemakers were required in 4 patients in the sutureless group (10.8%) and 1 patient in the TAVR group (2.7%). Neurological events occurred in 2 patients in each group. Higher paravalvular leak rates occurred in the TAVR group compared to sutureless group (13.5% vs 0%). At mean follow-up of 18.9 months, survival was significantly higher in the sutureless group (97.3% vs 86.5%). The authors suggested that AVR may be the first-line treatment for high-risk patients considered in the “gray zone” between TAVR and conventional surgery.

Biancari et al. [37] also compared the immediate outcomes of sutureless versus TAVR. There were 394 patients who underwent TAVR compared to 379 patients who underwent sutureless AVR. In-hospital mortality was 2.6% after sutureless AVR and 5.3% after TAVR. There was significantly higher mild paravalvular regurgitation (44% vs 2.1%) as well as moderate-severe paravalvular regurgitation (14.1% vs 0.3%). TAVR was also associated with higher pacemaker requirement (17.3% vs 9.8%).

Kamperidis et al. [38] evaluated 258 patients undergoing TAVR or sutureless AVR. Compared with the 3f Enable valve, TAVR prostheses (Edwards SAPIEN XT [Edwards Lifesciences, Irvine, California] and CoreValve [Medtronic]) had larger effective orifice area index, lower pressure gradient, less frequent prosthesis-patient mismatch, but more frequent AR. However, the survival of the 2 groups was comparable after 1.5-year follow-up. TAVR prostheses demonstrated better hemodynamics than the 3f Enable valve but a higher incidence of AR. However, these differences did not influence mid-term survival of patients.

Most recently, Miceli et al. [39] reported early and mid-term outcomes of MIAVR via anterior right mini-thoracotomy (ART) with sutureless valves versus TAVR for severe AS. From October 2008 to March 2013, 269 patients with severe aortic stenosis underwent either RT with perceval S sutureless valves ($n = 178$ patients, 66.2%) or TAVR ($n = 91$, 33.8%: 44 transapical and 47 trans-femoral). In the matched group, the in-hospital mortality rate was 8.1% in the TAVR group and 0% in the ART group. In the TAVR group, 37.8% had mild paravalvular leakage (PVL) and 27% had moderate PVL, whereas 2.7% had mild PVL in the ART group. One- and 2-year survival rates were 91.6 vs 78.6% and 91.6 vs 66.2% in patients undergoing ART with the perceval S sutureless valve compared with those undergoing TAVR. The authors concluded that MIAVR with Perceval S sutureless valves is associated with a trend of better early outcomes and mid-term survival compared with TAVR.

Takagi et al. [31] performed a meta-analysis of 7 observational comparative studies. The first pooled analysis demonstrated a statistically significant reduction in mortality with sutureless AVR over TAVR [2.5% versus 7.3%]. The second pooled analyses demonstrated no statistically significant difference in bleeding complications, acute kidney injury, and conduction disturbance between sutureless AVR and TAVR. The third pooled analysis demonstrated a statistically significant reduction in paravalvular AR with sutureless AVR over TAVR (3.5% versus 33.2%), consistent with prior studies. It was concluded that sutureless AVR may be associated with a reduction in early mortality and postoperative paravalvular AR.

CONCLUSION AND FUTURE RESEARCH

The implantation procedure for sutureless valves is different to conventional AVR, and requires proctoring for the surgeon to traverse the learning curve. Sizing the valve is absolutely important, and if the size is not ideal, paravalvular leaks, valve migration, and root dehiscence will be the catastrophic resulting complications. Given that sutureless AVR is still surgical procedure with AoX and CPB, associated complications may still occur.

Like other valves, sutureless aortic valves is also susceptible to “stent creep,” a permanent inward deflection of stent posts which may lead to valvular leak [40]. Therefore, sizing is still a critical assessment step during the use of sutureless aortic valves.

Furthermore, there is still a lack of long-term follow-up data available for sutureless valves and limited worldwide experience. Mid-term durability data for sutureless valves have been reported for 3-5 years follow-up, which is considerably less compared to the 20-25 years follow-up reported for some stented prostheses. Recently, the IVSSG has formulated to conduct the Sutureless Projects, a large international collaborative group to investigate this technology [18, 41, 42]. An international collaborative effort led by the IVSSG will hopefully set up to provide clinical robust evidence for the safety, efficacy and long-term complications profile for sutureless aortic valve technology.

Chapter 407

MINIMALLY INVASIVE AORTIC SURGERY

Tristan D. Yan*, MD, PhD

University of Sydney, Sydney Adventist Hospital, Sydney, NSW, Australia
University of Sydney, Royal Prince Alfred Hospital, Sydney, Australia

ABSTRACT

Thoracic aortic aneurysm (TAA) poses a silent and potentially deadly threat to those who harbor them. Clinicians ought to maintain a high index of clinical suspicion for patients with a possible TAA and offer prompt preemptive surgical intervention before devastating complications occur. An important objective in surgery is to reduce surgical trauma and achieve faster recovery for our patients. This chapter describes the technical details on how I perform *minimally invasive aortic surgery* via a mini-sternotomy access. The operation consists of 6 major steps: 1) mini-sternotomy, 2) cannulation, 3) aortic root exposition, 4) ‘French Cuff’ technique or double layer anastomosis, 5) coronary buttons re-implantation and 6) hemi-arch replacement. The success of the operation is a direct result of careful completion of these steps. The details of the ‘*French Cuff*’ technique are described in this chapter to show how to improve the hemostasis along the proximal annular anastomosis.

Keywords: aortic surgery, Bentall procedure, minimal access, minimally invasive, mini-Bentall

INTRODUCTION

The incidence of thoracic aortic aneurysm (TAA) is approximately 10 in 100,000 people [1]. It is a common aortic pathology requiring careful and prompt surgical evaluation. The symptoms associated with TAA can often be subtle, including those related to aneurysm expansion (e.g., chest pain or hoarseness) and compression (e.g., stridor). It is fair to say that that TAA is the ‘*Great Masquerader*’ (Figure 1), as many patients may be undiagnosed or

* Corresponding Author’s Email: tristanyan@annalscts.com.

misdiagnosed, until they present with death or catastrophic complications that threaten their lives, such as acute aortic dissection, aortic rupture, cardiovascular collapse and malperfusion syndrome. The first section of this chapter provides a general overview on TAA that highlights an important message: we, as clinicians, ought to maintain a high index of clinical suspicion for patients with a possible TAA and offer prompt preemptive surgical intervention before devastating complications occur.

A complete surgical repair of proximal TAA was first described by Hugh Bentall and Antony De Bono in 1968, using an inclusion technique [2]. This classic Bentall operation has undergone technical modifications over the years, mainly in an attempt to improve hemostasis. The modified Bentall operation, including composite graft replacement of the aortic valve, aortic root and ascending aorta, with re-implantation of the coronary buttons is now more widely performed. In recent years, several traditional cardiac procedures have been challenged by minimally invasive techniques. Mini-sternotomy or mini-thoracotomy approaches are increasingly used in our specialty to minimize surgical trauma and enhance patient recovery [3-7]. The second section of this chapter describes the details of my technique on how to perform minimally invasive aortic surgery via a mini-sternotomy approach, depicting six major surgical steps: 1) mini-sternotomy, 2) cannulation, 3) aortic root exposition, 4) ‘French Cuff’ technique, 5) coronary button re-implantation and 6) hemi-arch replacement. In particular, technical elements of “*French-cuff*” technique is highlighted. It cannot be emphasized enough that a meticulous surgical technique to ensure an absolute hemostasis is utmost important in minimally invasive aortic surgery.

Figure 1. Thoracic aortic aneurysm – a “Great Masquerader.”

THORACIC AORTIC ANEURYSM

Clinical Genetics of Thoracic Aortic Aneurysm

The genetic forms of thoracic aneurysms can be broadly divided into two categories: syndromic, which are typically associated with extra-aortic manifestations or the disease, and

non-syndromic, which lacks phenotypical features of body-wide syndromes. In recent years, greater understanding of specific mutations has permitted precise identification of affected patients, which in turn has further elaborated our understanding of the subtle differences in disease progression. Numerous genetic syndromes predispose individuals to TAA, accounting for 5% of all cases. Most prominent among these is Marfan syndrome, which causes progressive aortic root dilatation, necessitating surgery in 80% of patients by the age of 40, and almost all patients by the age of 60 [8]. Clinical diagnosis is based on the revised Ghent Nosology, incorporating family history, molecular testing, and clinical features [9]. Other syndromic forms of thoracic aortic aneurysms include Ehlers-Danlos syndrome, Loeys-Dietz syndrome, aneurysm osteoarthritis syndrome, and arterial tortuosity syndrome, which are similarly diagnosed by genetic testing and characteristic dysmorphic features.

Thoracic aneurysms not accompanied with phenotypical features of body-wide syndromes are classified as non-syndromic TAAs. This form is inherited in an autosomal dominant fashion with decreased penetrance and variable expression, exhibiting significant clinical and genetic heterogeneity. Non-syndromic TAAs can be further subdivided into sporadic TAA or familial TAA, depending on whether only one family member or if multiple family members are affected. Sporadic TAAs typically presents later in life than familial TAAs (mid-60s vs mid-50s), have a lower annual growth rate, and accounts for a greater majority of all TAA cases (80% vs 20%)[10]. In such patients, their aortic tissue can be extremely fragile, and prompt preemptive intervention is warranted.

BICUSPID AORTIC VALVE ASSOCIATED THORACIC AORTIC ANEURYSM

Bicuspid aortic valve (BAV) is the most common congenital heart condition, affecting 2% of the general population (Figure 2). BAV is a clinically heterogeneous disorder with a high rate of surgically relevant aortic valve and ascending aortic complications, which occur in over 35% of those affected [11]. As such, BAV confers a greater burden of disease than all other congenital heart diseases combined. Familial clustering and genetic studies have established that BAV has a heritable trait, with approximately 10% prevalence amongst first-degree relatives, and up to 25% in families with more than one affected family member [11].

TAA is common in BAV, reported in up to 50-60% of affected individuals [11, 12], predisposing them to aortic dissection or rupture. The histologic changes observed in bicuspid aortopathy are the end result of abnormal regulatory pathways of vascular smooth-muscle cells within the aortic media, leading to the release of matrix metalloproteinases, resulting disruption of the media layer, adversely affecting the structural integrity and flexibility of the aorta (Figure 3) [12]. Indeed, BAV conveys an eight-fold increased risk of aortic dissection, with a 26% risk for aneurysm formation at 25 years and 25% risk for aortic surgery [13]. As such, according to Class I recommendations by the American College of Cardiology Foundation (ACCF) and the American Heart Association (AHA) guidelines [14]:

1. First-degree relatives of patients with a BAV and/or a familial form of TAA and dissection should be evaluated for the presence of a BAV and asymptomatic thoracic aortic disease.

2. All patients with a BAV should have both the aortic root and ascending thoracic aorta evaluated for evidence of aneurysm.

Figure 2. Schematic drawings comparing tricuspid aortic valve morphology with three types of bicuspid aortic valve morphologies (Type 0 - no raphe; Type 1 - one raphe and Type 2 - two raphes).

Figure 3. Pathophysiological features of bicuspid aortopathy: A) in a healthy individual with tricuspid aortic valve, the smooth-muscle cells in the aorta are connected to the adjacent elastin and collagen matrix by fibrillin 1 microfibrils; B) in an individual with BAV, deficiency of fibrillin 1 initiates detachment of vascular smooth-muscle cells from the extracellular matrix, leading to the release of matrix metalloproteinases (MMPs), resulting in elastin and lamellar fragmentation and disruption of the media layer, adversely affecting the structural integrity and flexibility of the aorta.

SURGICAL INDICATION

The timing for surgery is largely based on presenting symptoms and the size of the aneurysm. The risks of aortic dissection, rupture and/or death increase exponentially if a TAA reaches 6 cm or bigger [14]. However, most of these complications can be forestalled by prompt preemptive surgical intervention when a TAA reaches 5.5 cm. Surgery should be considered even earlier if patients have a connective tissue disorders. Therefore, it is recommended that:

1. Patients with symptoms suggestive of expansion of a TAA should be evaluated for prompt surgical intervention unless life expectancy from comorbid conditions is limited or quality of life is substantially impaired
2. Asymptomatic patients with TAA, who are otherwise suitable candidates and for whom the ascending aortic aneurysm reaches 5.5 cm should be evaluated for surgical repair
3. Patients with connective tissue disorders (Marfan syndrome, vascular Ehlers-Danlos syndrome, Turner syndrome, or familial thoracic aortic aneurysm and dissection) should undergo elective operation at smaller diameters (4.0 to 5.0 cm) to avoid acute dissection or rupture
4. Patients with a growth rate of >0.5 cm/year in an aorta that is <5.5 cm in diameter should be considered for operation

PATIENT SELECTION CRITERIA

Patients with thoracic aortic aneurysms, affecting the aortic root, ascending aorta and/or aortic arch, may be considered for inclusion. Exclusion criteria in my practice included: redo cardiac procedure, emergency surgery, salvage surgery, infective endocarditis, concomitant coronary artery bypass surgery or valvular surgery (other than aortic valve) requiring full sternotomy access, and/or patient's refusal.

PREOPERATIVE ASSESSMENT

Initial assessment is performed using transthoracic echocardiography to evaluate proximal aorta and valvular pathology. To visualize distal ascending aorta, aortic arch and descending thoracic aorta, computed tomography (CT) thoracic aortogram is the most commonly used imaging modality as it provides detailed information regarding the size, location, and extent of the disease. The other imaging techniques include: chest X-ray, magnetic resonance imaging, trans-oesophageal echocardiography (TOE) and aortography.

A careful review of three-dimensional reconstructed images of the thoracic aorta in relation to the sternum and the rib cage is necessary, as this will greatly facilitate the planning for the mini-sternotomy. The degree of aortic wall calcification and evidence of atheromatous disease are evaluated in both contrast and non-contrast phases. A decision regarding the most appropriate cannulation strategy is sought with the aim to minimize potential embolic risks.

OPERATIVE STEPS

Following induction of anaesthesia, a radial arterial pressure monitor line with or without a femoral arterial pressure monitor line, central venous line, pulmonary arterial sheath/catheter and urinary catheter are inserted. The patient is placed in the supine position and the body surface anatomy is clearly marked with a permanent marking pen depicting the positions of supra-sternal notch, sterno-manubrial junction, 2nd to 4th intercostal spaces, the inferior extent of xiphoid cartilage and bilateral femoral arteries. The body is painted with an antiseptic solution, followed by positioning of the sterile drapes to expose the precordium laterally to the mid-clavicular lines and bilateral groin regions.

Mini-Sternotomy

A midline skin incision is performed from the manubrio-sternal junction to the level of the third intercostal space. This is usually 5-7 cm in length depending on the body size of the patient. The incision is developed through the subcutaneous fat onto the body of the sternum using diathermy, followed by the development of a cutaneous flap with a diathermy hand-piece along the prepectoral fascia. This flap is then extended superiorly above the supra-sternal notch and laterally to the limits of the sternum. A Kocker retractor is used to elevate the skin flap superiorly to expose the bridging vein over the manubrium and inferiorly to the 4th intercostal space. The bridging vein is clipped and cut. A 14 Fr Jackson Pratt drain (Cardinal Health, McGaw Park, IL, USA) is inserted through the skin at the level of 4th parasternal space on the left side and positioned in the subcutaneous space. This is used for CO₂ inflow during the case to prevent air embolism and as a subcutaneous drain at the completion of the operation.

A mini-sternotomy is performed using a hand-held electrical saw from the superior extent of the manubrium. The division is terminated either to the left or right para-sternal space. In this illustrated article, a left-sided, reversed “J” hemi-sternotomy is demonstrated (Figure 4). Hemostasis is achieved by applying a small amount of wax to the bone marrow. The thymic fat pad is completely mobilized to the innominate vein superiorly. The pericardium is opened longitudinally to the pericardial reflection superiorly and the level of 4th intercostal space inferiorly. Three pericardial traction sutures are placed on each side; hitched up and tied securely to the edges of the skin incision.

A minimally invasive sternal retractor is placed over the pericardial edges and opened up gradually. In doing so, the sternum is spread open, together with the pericardium, which anteriorizes the ascending aorta. A Semb clamp is passed around the ascending aorta by bluntly developing a plane between the mid-ascending aorta and the right pulmonary artery posteriorly and pulmonary artery trunk medially. The mid-ascending aorta is slung with a nylon tape and subsequent downward traction is applied to provide additional exposure of distal ascending aorta to facilitate aortic cannulation. This access would adequately expose the aorta from the level of sinotubular junction to that of the distal ascending aorta (Figure 5).

Figure 4. A midline skin incision is performed from the manubrio-sternal junction to the level of the third intercostal space. A reversed “J” upper hemi-sternotomy is terminated to the left fourth intercostal space.

Figure 5. The mid-ascending aorta is slung with a Nylon tape. The access should adequately expose the aorta from the level of sinotubular junction to that of the distal ascending aorta.

Cannulation Strategy

A vacuum-assist device is built in the cardiopulmonary bypass (CBP) circuit to maximize venous drainage. Full systemic heparinization is achieved with activated clotting time (ACT) greater than 450 seconds. Peripheral venous cannulation is established first, using a Seldinger

technique. After puncture of a femoral vein, a guide wire is passed up to the superior vena cava. The position of the wire is confirmed with TOE through a bicaval view. The femoral vein puncture site is then progressively dilated. A 23 or 25 Fr multi-stage venous cannula (Maquet Getinge Group, Rastatt, Germany) is introduced. The pointy-tipped insert is not advanced further once it enters the right atrium. Only the venous cannula itself is now advanced forward over the insert under strict TOE guidance. It is essential that the cannula tip be placed in the superior vena cava to ensure satisfactory bicaval venous return. The venous cannula is subsequently connected to the CPB circuit.

Arterial cannulation can be established via either the distal ascending aorta or the femoral artery. In this chapter, a distal ascending aortic cannulation is depicted. The nylon tape slung around the mid-ascending aorta is retracted inferiorly. The superior edge of the skin incision is elevated cephalad using a Kocker tractor. Two 2-0 Ti-Cron purstrings for the aortic cannula are placed in the distal ascending aorta at the level of pericardial reflection. The aorta is carefully cannulated with an Elongated One-Piece Arterial (EOPA) cannula (Medtronic Inc, Minneapolis, MN, USA), which is secured in position and connected to the CPB circuit.

A 16 Fr DLP pulmonary artery vent cannula (Medtronic Inc, Minneapolis, MN, USA) is inserted in the main pulmonary trunk (Figure 6). Once CPB is established, the heart is off-loaded. Systemic temperature is maintained at 32 degrees centigrade for aortic root replacement or 25 degrees if hemi-arch replacement is anticipated. In the latter, splitting the arterial line is necessary beforehand to provide additional cerebral perfusion.

Figure 6. Cardiopulmonary bypass is established via central aortic cannulation and femoral venous cannulation. A 16 Fr DLP pulmonary artery vent cannula (Medtronic Inc, Minneapolis, MN, USA) is inserted in the main pulmonary trunk.

Aortic Root Exposition

Under a low-flow condition, an atraumatic aortic cross-clamp is applied across the distal ascending aorta. Diastolic arrest is achieved with antegrade cardioplegia delivered via a DLP aortic root cannula (Medtronic Inc, Minneapolis, MN, USA) or direct coronary ostial balloon tip cannula (Maquet Getinge Group, Rastatt, Germany) in the presence of aortic regurgitation. Either cold-blood cardioplegia solution or Custodiol cardioplegia solution (Koehler Chemi, Alsbach-Haenlien, Germany) is suitable.

After aortotomy, the blood in the aortic root is salvaged. The aneurysmal segment of the ascending aorta is resected, leaving 1 cm cuff of aortic tissue proximal to the cross-clamp and 1 cm above the sinotubular junction (Figure 7). The inside of the aortic root is assessed and the positions of the coronary arteries are visualized. The aortic root is carefully mobilized circumferentially. Subsequently, the non-coronary sinus is resected, leaving an 8 mm rim of aortic wall just above the non-coronary annulus. Then, the right coronary button flap is prepared. Two vertical incisions are made from the sinotubular junction down along both sides of the right coronary ostium and connected inferiorly (Figure 8). A 4-0 polypropylene suture is passed through the top end of the right coronary button flap to provide gentle traction when required. Similarly, the left coronary button flap is also fashioned. Often only limited mobilization of the coronary buttons from the surrounding connective tissue is required.

Figure 7. The ascending aortic aneurysm is resected, leaving 1 cm cuff of aortic tissue proximal to the cross-clamp and 1 cm above the sinotubular junction.

Figure 8. The aortic root is carefully mobilized circumferentially and resected, leaving a rim of aortic wall just above the aortic annulus. The coronary buttons are prepared.

Figure 9. To provide an excellent exposure, the aortic root is brought in the cephalad direction by pulling on three commissural traction sutures.

In order to provide an excellent exposure, the aortic root is brought in a cephalad direction. This is achieved by putting the first pledgeted 2-0 Ti-Cron horizontal mattress suture above the non-/left-coronary commissure. The needles are then passed through the edge of the skin incision on the right side, at the 10 o'clock position. The traction suture is snared and clipped. The needles of the next pledgeted 2-0 Ti-Cron suture are passed through just above the left-/right-coronary commissure and the skin edge on the left side at the 2 o'clock position. The third pledgeted 2-0 Ti-Cron traction suture is used to elevate the right-/non-coronary commissure and attached to the skin edge on the right side at the 7 o'clock position. These three commissural traction sutures are hitched up and snared in position. This simple manoeuvre provides an excellent exposure of the aortic valve for the minimal access surgical approach (Figure 9). The aortic leaflets are resected and the aortic annulus is decalcified (Figure 10). Horizontal mattress sutures are placed neatly below the aortic annulus, using 2-0 Ethibond *Excel* annular sutures with or without pledgets. Pledgets can help to reduce the tension created by the sutures when the valve conduit is tied down, especially at the nadirs. The placement of these sub-annular sutures needs to be precise, both in terms of the spacing and whether or not the needle is passed through the annulus at a perpendicular angle (Figure 11). The sutures are evenly distributed.

Figure 10. The aortic leaflets are resected and the aortic annulus is decalcified.

Figure 11. Horizontal mattress sutures are used, with pledgets placed neatly below the aortic annulus.

‘French Cuff’ Technique

The annulus is sized for its intra-annular and supra-annular dimensions. An appropriate prosthetic valve is selected, as one would do for routine aortic valve replacement, although it is advisable not to oversize the valve. A Valsalva graft (Vascutek Ltd, Renfrewshire, Scotland) is selected according to this formula: *Valsalva Graft Size = Aortic Valve Size + 5mm* (at least 3mm). Subsequently, the following steps are followed for the ‘French Cuff’ technique. The details of the French Cuff Technique are published elsewhere [15].

Step 1: The proximal cuff of the Valsalva graft is trimmed down to 8mm. This cuff is folded back over the outside of Valsalva portion of the graft to make a double cuff, the eponymous ‘French Cuff’.

Step 2: The prosthetic valve is positioned inside of the Valsalva graft. The annular sutures are passed through the sewing ring of the prosthesis first and then the folded proximal edge of the Valsalva graft. Once all the sutures are passed through, the valve and the graft are parachuted down onto the annulus (Figure 12). The sutures are tied and cut sequentially around the sewing cuff. This completes the first proximal layer anastomosis.

Step 3: The second ‘hemostatic’ layer is performed using a 4-0 running Polypropylene suture, starting from the commissure between the left and right annulus and progressing clock-wise circumferentially. It is important to ensure that this layer of running suture incorporates the remnant of aortic wall and the everted ‘French Cuff’ edge. In addition, constant tension on the suture needs to be maintained by the assistant when following the suture.

If a mechanical valve conduit (St. Jude Medical, St. Paul, MN, USA) is used and there are any concerns regarding the hemostasis along the annulus (due to suture spacing or severely calcified annulus), a second ‘hemostatic’ layer can be achieved by using a continuous 4-0 running polypropylene suture that incorporates the 8 mm remnant of the aortic wall and the sewing cuff of the valve conduit. This ‘double layer’ anastomosis technique works well for a mechanical valve conduit, as the sewing cuff is big enough to accommodate two rows of anastomoses.

Figure 12. The valve and the conduit are parachuted down by gently pulling the sutures vertically upwards with one hand and firmly pushing the valve conduit down onto the annulus with the other.

Coronary Button Re-Implantation

The left coronary artery button is rested in its anatomical position. The appropriate site on the aortic root for the Valsalva graft (Vascutek Ltd, Renfrewshire, Scotland) for left coronary button re-implantation is determined with the heart fully loaded, so that there is no tension or rotation of the left coronary button anastomosis. Once the position of the anastomosis is marked, the heart is off-loaded. A Bovie electrocautery (Bovie Medical Corporation, Clearwater, FL, USA) is used to create a circular hole for receiving the left coronary button. The coronary button is trimmed to a 3 mm circumferential cuff and re-implanted using a 5-0 running polypropylene suture. The cuff of the coronary button needs to be attached snugly to the outside of Valsalva graft (Figure 13). The right coronary button is prepared and re-implanted in a similar fashion (Figure 14). It is imperative to ensure that a full thickness bite with each stitch is achieved. Failing to do so may cause bleeding in a very difficult site to access once the cross-clamp is taken off. The aortic root is pressurized and the anastomoses are tested by delivering a full dose of antegrade cardioplegia. Systemic rewarming is subsequently initiated.

The distal aortic anastomosis is reconstructed with the aortic cross-clamp on. The length of the graft is determined by filling the heart up and pulling the graft upwards on a stretch to meet distal ascending aorta. The graft is trimmed and anastomosed to the distal ascending aortic cuff by using a 3-0 running polypropylene suture. The anastomosis is started from the point furthest away from the operating surgeon. The posterior wall is completed first from 4 o'clock to 11 o'clock position on the aorta (Figure 15). A nerve hook is used to tighten the posterior wall suture progressively towards the operating surgeon. The anterior half of the anastomosis is completed by picking up the other end of the suture and sewing towards the operator. An aortic root vent is inserted before the two ends of the suture are tied. The table is then put in a Trendelenburg position, the heart is filled and lungs are inflated, the arterial flow is turned down, aortic cross-clamp is released and the graft is de-aired from the aortic root vent.

Figure 13. The left coronary button is trimmed, leaving a 3 mm circumferential cuff and re-implanted using a 5-0 running polypropylene suture.

Figure 14. The right coronary button is prepared and re-implanted using a 5-0 running polypropylene suture.

Figure 15. The graft is trimmed and anastomosed to the distal ascending aortic cuff by using a 3-0 running polypropylene suture.

Hemi-Arch Replacement

If the distal ascending and/or proximal arch is aneurysmal, a hemi-arch replacement with an open distal anastomosis is performed. Two cerebral perfusion cannulae are prepared at the beginning of the case in readiness for antegrade cerebral perfusion. Systemic cooling down to 25 degrees is initiated.

Figure 16. The mid to distal ascending aorta is resected completely, together with the cannulation site. Selective antegrade cerebral perfusion is achieved by cannulating the innominate artery with or without left common carotid artery.

Figure 17. The open distal anastomosis is performed with a separate Ante-Flo graft with a single side arm (Vascutek Ltd, Renfrewshire, Scotland), using a continuous 3-0 running polypropylene suture.

As soon as the systemic temperature reaches 25 degrees, attention is then turned to the distal hemi-arch replacement. At this stage, the head is packed in ice, the antegrade flow is ceased, the aortic cannula is clamped, the aortic cross clamp is removed and the patient's blood is drained into the reservoir. The mid to distal ascending aorta is resected completely, together with the cannulation site, and the under surface of the proximal aortic arch is beveled. The inside of the aortic arch and the origins of epi-aortic vessels are inspected for

any evidence of atheromatous disease. Selective antegrade cerebral perfusion is achieved by cannulating the innominate artery with or without left common carotid artery (Figure 16). The open distal anastomosis is performed using a separate Ante-Flo graft with a single side arm (Vascutek Ltd, Renfrewshire, Scotland). A continuous 3-0 running polypropylene suture is used, starting from the point furthest away from the operating surgeon and completing the posterior aortic wall first (Figure 17). A nerve hook is used to tighten the suture along the posterior wall. The anterior half of the anastomosis is completed by picking up the other end of the suture and sewing towards the operator. This distal anastomosis is reinforced with pledgeted 4-0 prolene sutures where necessary to ensure absolute hemostasis. After completion of the open distal anastomosis, antegrade systemic perfusion is resumed via the side-arm perfusion limb of the Ante-Flo graft. The patient is rewarmed towards 37 degrees centigrade.

Figure 18. A graft-to-graft anastomosis is performed using a continuous 3-0 running polypropylene suture and reinforced using pledgeted 4-0 polypropylene sutures where necessary.

Once the root procedure is completed, the proximal valve conduit is trimmed just above the Valsalva portion of the graft. The distal Ante-Flo graft is put under a stretch and cut to an appropriate length. A graft-to-graft anastomosis is performed using a continuous 3-0 running prolene suture (Figure 18). The spacing between the adjacent stitches needs to be narrow and precise when doing a graft-to-graft anastomosis, usually a couple of millimeters apart. Finally, the aortic root vent is inserted, the aortic cross clamp is slowly released and a 21-gauge needle is used to de-air the graft. In order to ensure an absolute hemostasis, pledgeted 4-0 prolene sutures are applied to reinforce the proximal anastomosis when necessary.

Completion

A bi-polar temporary pacing wire is inserted in the epicardium over the right ventricular outflow tract. One 28 Fr soft drain is inserted and brought out below the xiphoid cartilage. Hemostasis is carefully checked and the patient is weaned from CPB. Protamine is given to reverse the heparin effect. Topical Floseal Hemostatatic Matrix (Baxter Healthcare, Zurich, Switzerland) is applied around the anastomotic sites. The surgical site is packed with small

gauze sponges for a period of 10-minute hemostatic pause. Once the hemostasis is deemed satisfactory, four stainless steel wires are used to approximate the sternum. No. 1 Vicryl suture is used to close the fascia and the subcutaneous fat. The skin is closed with a 5-0 Monocryl subcuticular suture. This completes the minimally invasive aortic surgery.

DISCUSSION

An important goal in modern cardiovascular surgery is reducing surgical trauma to achieve faster recovery for our patients. The benefits of minimally invasive surgery are evident [3-7]. Surgeons are comfortable with aortic valve replacement via upper hemi-sternotomy or right mini-thoracotomy, and thus naturally there is a growing interest in performing aortic surgery via a minimal access incision. The present chapter described my technique on how to perform Mini-Bentall Procedure and hemi-arch replacement for elective surgical patients with aortic root and ascending aortic aneurysms.

The mini-sternotomy is performed using a hand-held electrical saw from the superior extent of the manubrium, with the division terminated either to the left or right para-sternal space. One advantage to the right (a “J” mini-sternotomy) is avoiding any potential injury to the left internal mammary artery, should it be used for coronary bypass surgery in the future. In addition, access to the right superior pulmonary vein for venting is made easier. The main advantage of performing a mini-sternotomy to the left (a reverse “J”) is increasing the exposure of proximal arch, especially if a concomitant hemi-arch replacement is anticipated. Under this circumstance, a pulmonary artery vent is used instead of right superior pulmonary vein vent. It should be cautioned that when inserting a pulmonary artery vent, the heart needs to be kept full or even before going on cardiopulmonary bypass. This will avoid injury to the posterior wall of the pulmonary trunk with the tip of the pulmonary artery cannula.

Arterial cannulation can be established either via distal ascending aorta or femoral artery. It is preferable to employ central arterial cannulation whenever possible to provide adequate antegrade systemic perfusion and avoid potential retrograde embolization and vascular complications that may be associated with peripheral cannulation [16]. Should femoral arterial cannulation be used, a 2.5 cm oblique incision is performed in the groin, exposing the anterior aspect of the common femoral artery. A 5-0 polypropylene purse-string suture is placed in the anterior aspect of the common femoral artery. The artery is cannulated using a Seldinger technique. A guide wire is passed up in the descending thoracic aorta. Its presence within the descending aorta is confirmed with TOE. After progressive manual dilatation of the femoral artery puncture site, a wire-reinforced femoral arterial cannula should be inserted without any resistance.

In order to provide adequate exposure and surgical accessibility, it is important to anteriorize the aortic root, as well as bring the aortic annulus cephalad. This is achieved by placing three pledgeted 2-0 Ti-Cron horizontal mattress sutures above the commissures and hitching them up to the skin edges. This simple manoeuvre provides an excellent exposure of the aortic valve for the minimal access surgical approach. Even though the mini-sternotomy terminating at the level of sinotubular junction, this manoeuvre can bring the aortic annulus forward in the cephalad direction by 2 to 3 cm.

Composite graft replacement of the ascending aorta and aortic valve was first introduced by Bentall and De Bono in 1968 [2]. According to this technique, the aortic tissue surrounding the coronary ostia is directly sutured to the openings in the composite graft. These anastomoses were all made within the ascending aorta, and then the aortic wall is tightly wrapped over the conduit. This technique has been known as the wrap/inclusion technique [2]. Coronary artery dehiscence and coronary false aneurysms may result from tension created by bleeding into the space between the graft and the wrap [17]. A few technical modifications have been implemented, including the use of a reinforcement suture joining the cut edge of the aortic wall and the prosthetic sewing ring [18]. This technique described two separate proximal suture lines, an interrupted one between the most proximal part of the valve sewing ring and the aortic valve annulus, and a continuous one between the more distal portion of the sewing ring and the cut edge of the proximal aorta. In a Mini-Bentall Procedure, absolute hemostasis must be achieved. If there are any concerns regarding the hemostasis along the annulus (due to suture spacing or severely calcified annulus), a second ‘hemostatic’ layer is achieved by using a continuous 4-0 running polypropylene suture that incorporates the 8 mm remnant of the aortic wall and the sewing cuff of the valve conduit. This technique works well for a mechanical valve conduit as the sewing cuff is large enough to accommodate two rows of anastomoses. However, when a bioprosthetic valve is used inside of a valsalva graft, whereby the sewing ring of the tissue valve is narrow and the second ‘hemostatic’ layer is difficult to achieve, a ‘French Cuff’ technique can be used [15].

In the strategy presented, the fundamental principles of a traditional aortic root replacement are respected and it cannot be emphasized enough that a meticulous surgical technique to ensure absolute hemostasis is of the utmost importance in minimally invasive surgery. This results in a complete aortic repair via a minimal access incision and successful treatment in selected patients with aortic root, ascending aortic aneurysm and/or proximal arch aneurysms.

Chapter 408

THE EFFECTS OF DEXAMETHASONE IN PRE AND POST OPERATIVE SURGERY

Jun-Beom Park*, DDS, PhD

Department of Periodontics, College of Medicine, The Catholic University of Korea,
Seoul, Republic of Korea

ABSTRACT

Dexamethasone is reported to be a potent synthetic member of the glucocorticoid class of steroid drugs. It acts as an anti-inflammatory and immunosuppressant. Dexamethasone has been used before, during and after surgery.

In this paper, extensive review of the role of dexamethasone before, during and after the surgery will be performed using in vivo and clinical studies. Clinical implications of dexamethasone will be also conducted.

Keywords: analgesia, dexamethasone, nausea, pain, pain management, vomiting

INTRODUCTION

Dexamethasone is a potent synthetic member of the glucocorticoid class of steroid hormones [1]. Dexamethasone is a steroidal anti-inflammatory drug that induces annexin, a protein that, among other actions, is capable of inhibiting phospholipase A2 (i.e., the enzyme responsible for the induction of arachidonic acid) [2, 3]. The arachidonic-acid cascade initiation culminates in the expression of prostaglandins, prostacyclins, thromboxanes, and leukotrienes, which are related to pain [4]. It also suppresses the production of free oxygen radicals and nitric oxide by endothelial cells [5].

Dexamethasone has been used before, during and after surgery. In this paper, extensive review of the role of dexamethasone before, during and after the surgery will be performed

* Corresponding Author's Email: jbassoonis@yahoo.co.kr; Fax: +82-2-537-2374.

using in vivo and clinical studies. Clinical implications of dexamethasone will be also conducted.

EFFECTS OF DEXAMETHASONE

Post-operative assessment of pain and discomfort showed that persistent discomfort and pain were found to be more in the placebo group compared to dexamethasone group [3]. The adoption of a preemptive medication protocol using dexamethasone may be considered effective for pain and discomfort prevention after open-flap debridement surgeries [3]. Co-therapy with non-steroidal anti-inflammatory drugs and steroids was suggested to provide beneficial inflammatory and pain relief in the absence of side effects [6]. It was seen that co-administration of dexamethasone and diclofenac potassium (non-steroidal anti-inflammatory drug) was significantly superior to diclofenac potassium alone for the relief of pain in third molar surgery [6].

The results previous study indicated that the use of intraoperative dexamethasone is an effective therapeutic strategy for limiting trismus following surgical removal of impacted third molars [7]. Postoperative swelling and edema may be due in part to the conversion of phospholipids into arachidonic acid [7].

Dexamethasone, plus a 5-HT₃ receptor antagonist and an NK-1 receptor antagonist are recommended for controlling the chemotherapy-induced nausea and vomiting of highly emetogenic chemotherapy [8]. Moreover, previous report showed that continuous dexamethasone treatment facilitated osteogenic, adipogenic and chondrogenic differentiation [9].

DOSAGE

Application of dexamethasone was performed with 8 mg of dexamethasone parenterally 30 minutes before operation and 4 mg of dexamethasone intravenously, 6 hours postoperatively [6]. In other report, 8 mg dexamethasone was given orally 1 hour prior to surgery or immediately before induction of anesthesia [3, 10]. In other study, dexamethasone 10 mg was applied intravenously during the operation [7].

Dexamethasone 12 mg was administered intravenously on day 1, and then 8 mg of dexamethasone was applied intravenously on day 2 and 3 for controlling nausea and vomiting [8].

MECHANISM

The conversion of phospholipids into arachidonic acid is done by phospholipase A₂ and the resultant production of leukotrienes, prostacyclins, prostaglandins, and thromboxane A₂ act as mediators of the inflammatory response [7]. And the use of dexamethasone is reported to inhibit the initial step in this process.

META-ANALYSIS OF PAIN RELIEF

Differences in relief of pain between dexamethasone and placebo from meta-analysis are shown in Figure 1. The results showed that the additional use of dexamethasone was found to be associated with enhanced pain relief (odds ratio=8.981, 95% confidence of interval=5.454, 14.790).

CONSIDERATION

The time needed for dexamethasone to reach a plasmatic-concentration peak varies from 1 to 2 hours, and there were favorable results with its use 1 or 2 hours before surgery [4]. After an 8-mg dose of dexamethasone, elimination half life ($t_{1/2}$) and volume of distribution (Vd) are 3 hours and 1.0 liter $\times$ kg⁻¹, respectively [5, 11].

Figure 1. Differences in relief of pain between dexamethasone and placebo from meta-analysis.

CONCLUSION

A number of studies have demonstrated the various effects of dexamethasone on surgical procedures. Relatively abundant information about dexamethasone indicates their possible beneficial effects on relief of pain and postoperative complications.

Chapter 409

QUALITY OF LIFE CHANGES RELEVANT TO EXTENT OF THYROID SURGERY

Fatima Z. Syed*, MD

Division of endocrinology, Thomas Jefferson University Hospital,
Philadelphia, PA, US

ABSTRACT

One of the most frustrating facets of clinical thyroidology is to deal with the unhappy patients who have iatrogenic post-surgical hypothyroidism. These patients frequently have complaints of brain fog, weight gain and fatigue without any easy “fix”.

These symptoms predominate frequently in the post-operative patient and are obviously real because they occur so frequently! “Prevention is better than cure” so we need to, where appropriate, minimize the extent of thyroid surgery as it would appear that some endogenous remaining thyroid hormone minimizes these symptoms as opposed to no endogenous thyroid function where these symptoms predominate. Future efforts need to be directed to more adequately defining appropriate thyroid hormone replacement and which compounds fare best? Finally perhaps the future rests on stem cell or related technique to retain endogenous thyroid hormone function?

Dr Syed addresses these issues in her narrative and provides some guide in minimizing extent of thyroid surgery where appropriate as well as attempts to appropriately replace physiological thyroid hormones and which compounds to use?

CASE REPORT ONE

Mrs. DS is a 65 year-old Caucasian female with history of well-controlled hypertension. Four years ago, she presented with a left sided two-centimeter thyroid nodule. Biopsy was consistent with papillary thyroid cancer, classical variant. She underwent a total thyroidectomy. Pathology was consistent with papillary cancer classic type 2cm in size. She did not have vascular invasion nor did she have any lymph node involvement. She did not

* Corresponding Author's Email: Fatima.syed@jefferson.edu.

receive radioactive iodine. Today, she presents to you for follow-up. At each visit in the last four years, she complains of fatigue, which did not exist prior to her surgery. Utilizing the Brief Fatigue Inventory, she states that she is fatigued at a score of 7/10 currently. At her worst, her fatigue is 10/10. Most of the time, she lives near a fatigue score of 8/10. She states that the fatigue affects her mood, her ability to exercise, and has interfered with work. She had planned on working into her 70s but states she feels so tired, she retired from her work as an accountant last year. She attributes the fatigue beginning after her thyroidectomy. She has been on a steady dose of levothyroxine 112 mcg for many years and has been biochemically euthyroid at your last five visits together. She ends the appointment by stating, "I wish I had never gotten my thyroid removed."

CASE REPORT TWO

Ms. Y is a 33 year-old East Asian female with history of papillary thyroid cancer status post total thyroidectomy here for follow-up. Three years ago, during a routine GYN visit, she was noted to have a right-sided thyroid nodule. She had no history of radiation in the past and she had no family history of thyroid cancer or other malignancies. She underwent a biopsy of the nodule, which came back as papillary thyroid cancer. She underwent total thyroidectomy and had a 3 cm nodule with classical PTC showing lymphovascular invasion. She received radioactive iodine as well. She comes today for follow-up. She is on levothyroxine at 100 mcg daily. She has been biochemically euthyroid for over one year. She complained of having low energy. She feels she is not functioning as well as she should and sleeps poorly at night. She screens negative for depression and has no other medical issues or stressors. She does have an eight month old daughter. However, her daughter is sleeping through the night and she does not believe motherhood is the source of her fatigue. She states that since her thyroidectomy and starting thyroid replacement, she has never felt the same.

CASE REPORT THREE

Mr. W is a 46 year-old who was diagnosed with papillary thyroid cancer, classic variant seven years ago upon discovering a palpable nodule on the right side of his thyroid whilst shaving one morning. He underwent biopsy, which showed the results as stated. He has no exposure to radiation. His mother also had papillary thyroid cancer and underwent total thyroidectomy. He was referred for surgery. It was ultimately decided that patient would undergo a right lobectomy as the nodule was only 2cm in size. Pathologically the right lobe showed 18mm papillary thyroid cancer without lymphovascular invasion. Post-operatively his thyroid function remained within normal range without the need for thyroid hormone replacement. He did however have minimal weight gain and complaint of fatigue in follow up.

INTRODUCTION

“I haven’t been the same since my thyroid was removed.” This is a common complaint endocrinologists hear from patients who have undergone total thyroidectomy. Before examining symptoms associated with thyroidectomy, it is first important to understand the role of the thyroid and the effects and treatment of hypothyroidism. The most common cause of hypothyroidism globally is iodine deficiency [1]. However, in the United States and other developed nations, the most common cause of hypothyroidism is autoimmune thyroid disease [2]. Amongst leadership in clinical guidelines, screening for hypothyroidism is not generally recommended. However, in cases of other autoimmune disease, family history, history of radiation, or personal history of thyroid surgery, screening of thyroid function is recommended. Of course, if a patient has symptoms of hypothyroidism, he or she should be screened [2, 3].

Patients who have their thyroid gland surgically or radioactively removed require lifelong thyroid replacement [2]. Typically, thyroid replacement involves replacing levothyroxine at 1.6 micrograms/kilogram for all patients [4], regardless of the etiology of hypothyroidism. However, according to the American Thyroid Association, patients who have had surgical thyroidectomies may require more replacement [2]. This can be adjusted based on symptoms of the patient. Thyroid replacement is therefore based on both qualitative and quantitative measures.

Traditionally, patients that are status post thyroidectomies TSH are initially suppressed and then are maintained to be biochemically euthyroid [5]. However, in our case reports above, we find a common complaint amongst these patients is that they may not feel as they did before thyroidectomy, despite effective treatment of thyroid hormone replacement. The aim of this chapter is as follows:

1. Examine quality of life for patients who have undergone thyroidectomies
2. Understand the objective measurement tools of quality of life
3. Review treatment options of PTC and examine morbidity and mortality associated with PTC
4. Understand the perceptions of lobectomy versus thyroidectomy

OBJECTIVE MEASUREMENTS OF QUALITY OF LIFE

In evaluating patients with history of thyroidectomies, it is important to ask the symptoms the patient experiences as well as if those symptoms are tolerable or not. This can help guide supportive care for the patient. Several objective measures on quality of life can be applied to patients who have had total thyroidectomies.

Massolt et al. describe the following quality of life measures [5].

Thyroid Specific Patient Reported Outcome Measures (ThyPRO)

This is a qualitative survey containing eighty-five questions summarized in 13 scales. It accounts for cross-cultural [6, 7] and socio-economic validity [5].

Multidimensional Fatigue Index (MFI-20)

This is a twenty-question survey which evaluates generalized fatigue, physical fatigue, mental fatigue, reduced motivation and reduced activity [5, 8].

RAND-36

This is a validated Dutch survey on evaluating overall health in the prior thirty days [9]. It consists of nine subclasses, including physical health problems, limitations of emotional and general health care needs.

Cancer Quality of Life Survey

This is a survey typically for patients before and after chemotherapy, however it is also helpful in evaluating depression and fatigue in patients with history of cancer [5].

THYROIDECTOMY PATIENTS PERCEPTIONS OF QUALITY OF LIFE VERSUS AGE NORMATIVE POPULATIONS

In a study by Husson et al, quality of life of patients with thyroidectomy is compared to age normative populations [10]. Consistently, it is found that patients with thyroidectomy have decreased quality of life compared to age normative populations. Patients with thyroid cancer have comparable life expectancies as patients without thyroid cancer [11]. Given the length of life expected by these patients, according to the study, any impacts to quality of life become concerning. The study aims to “assess [thyroid cancer specific] Health Related Quality of Life (HRQoL) among long-term thyroid cancer survivors and to compare this with the HRQoL of an age- and sex-matched normative population. Secondly, our aim was to investigate which clinical and socio-demographic characteristics and thyroid cancer specific problems were associated with HRQoL” [10].

The study surveyed patients over a twenty-year period of new patients diagnosed with thyroid cancer. It used objective surveys to assess disease specific symptoms. These scores were then compared with age and sex matched disease free controls. Confounding factors such as socio-economic status were addressed [10].

The study found that “Thyroid cancer survivors had significantly lower scores on physical, role, emotional, cognitive and social functioning ($p < 0.001$) compared to the normative population after adjusting for comorbidities. Sympathetic problems [feeling chilly

(52%), hot flushes (40%)], neuromuscular problems [cramp legs (43%) and pain joints/muscles (64%)] and abrupt attacks of fatigue (50%) were the most often reported thyroid cancer specific complaints. Thyroid cancer specific neuromuscular, concentration, sympathetic and psychological problems explained 41–58% of the variance in HRQoL. Clinical and socio-demographic factors explained a small part of the variance in (thyroid cancer specific) HRQoL (1–27%)” [10].

Further studies have shown that patients with thyroid cancer who have undergone thyroidectomy are at higher risk of unemployment [12]. Patients report fatigue as reasons for unemployment. It is difficult to correlate fatigue alone as reason for unemployment, which is a complicated issue. However, the correlation with thyroid cancer survivorship does indeed exist [12].

Overall, patients who have thyroid cancer and survived will likely have worse quality of life had they never had thyroid cancer and required a thyroidectomy [13]. There is not objective data as to why patients with thyroidectomy have worsened quality of life. Obvious thought is that the thyroid produces some endogenous substance [5], which contributes to energy that is beyond thyroid hormone alone. Additionally, many with PTC have some component of autoimmune thyroid disease [2]. Autoimmunity itself may not disappear after surgery, and it is possible, this is causing the residual fatigue and impairment to perceived quality of life [5, 14].

THYROIDECTOMY VERSUS LOBECTOMY IN TREATMENT OF THYROID CANCER AND EFFECTS ON QUALITY OF LIFE

According to a study done at Memorial Sloan Kettering over a twenty- year period, there was no difference in mortality in patients who received a total versus partial lobectomy for non-invasive thyroid cancer [15]. This study only included patients with thyroid cancers that were less than or equal to 4 cm in size and with no known invasion of lymph nodes or spread outside the neck. “A total of 361 patients were treated with lobectomy and 528 were treated with total thyroidectomy. As expected, the survival at 10 years was high in both groups of patients (93% in the lobectomy and 91% in the total thyroidectomy group). There were no significant differences in 10 year survival or thyroid cancer recurrence between the two groups of patients. Both age greater than 45 and male gender were predictive of a worse overall survival, while the type of surgery had no effect on survival” [15].

According to Husson et al. and other studies, patients with lobectomy still report worse quality of life in comparison to those without thyroid cancer [10].

CONCLUSION

In all three cases, the commonality was that patients felt worse after thyroidectomy than before. There are many reasons this could be the case. In those with cancer survivorship in general, quality of life is perceived worse after cancer than before even decades after cure [16]. Therefore, thyroid cancer, although mostly has high levels of long term survivorship, is not different than other cancers. Perhaps evaluating patients’ quality of life before and after

would be helpful in evaluating their perceptions of symptoms. Also in low risk thyroid cancer perhaps minimalistic surgery (lobectomy), leaving patients with some functioning thyroid tissue of their own, may alleviate some of the fatigue and weight gain attendant with total thyroidectomies without compromising longevity nor recurrence risk?

Chapter 410

**BIOLOGICAL CHARACTERISTICS, CLINICAL
CLASSIFICATION, AND SPASM OF ARTERIAL GRAFTS
AND ANTISPASTIC MANAGEMENT IN CORONARY
ARTERY BYPASS GRAFTING SURGERY**

Guo-Wei He^{*}, MD, PhD

TEDA International Cardiovascular Hospital, Chinese Academy of Medical Sciences &
Peking Union Medical College, Tianjin & The Affiliated Hospital of Hangzhou Normal
University & Zhejiang University, Hangzhou, China,
Department of Surgery, Oregon Health and Science University,
Portland, OR, US

ABSTRACT

CABG surgery has been the standard treatment for patients with coronary artery disease, particularly for three-vessel disease, although PCI has become the preferred method in one- or two-vessel disease. Arterial grafting using autologous arteries as the bypass grafts has been demonstrated to have superior long-term results. Arterial grafts can be classified Type I, II, and III for clinical consideration according to their biological characteristics. Use of the left internal mammary artery to graft the diseased LAD has become the standard method for almost all CABG surgery and bilateral IMA grafts may further enhance survival over the long-term. The radial artery is also commonly used as a bypass graft, and occasionally the right gastroepiploic artery, and inferior epigastric artery. However, in comparison to vein grafts, arterial grafts have a tendency to develop vasospasm that can lead to potentially life-threatening complications. Various antispastic pharmacologicals have been used during surgery but the rationale and efficacy are sometimes unclear and there is still controversy as to what is the most effective regimen. This is partially due to the pathophysiological complexity of the mechanism of vascular spasm and, consequently, the evolution of several pharmacological vasodilators. Better understanding of the mechanism of vascular spasm, development of new pharmacological vasodilators, and the adequate evaluation of non-pharmacological

^{*} Corresponding Author's Email: gwhezej@163.com; Fax: 86-22-6520 8732.

methods may lead to a more unanimous opinion as to the best method to prevent and treat arterial spasm in contemporary clinical practice.

1. INTRODUCTION

CABG surgery has been the standard treatment for patients with coronary artery disease (CAD), particularly for three-vessel disease, although over the past decade, percutaneous coronary intervention (PCI) has gradually become the preferred method of revascularization in patients with one-vessel or two-vessel disease [1, 2]. Arterial grafting, i.e., using autologous arteries rather than veins as the grafts, has been demonstrated to have superior long-term results compared to vein grafts [3]. In particular, use of the left internal mammary artery (IMA) to graft the diseased LAD has become the standard method for almost all CABG surgery [4, 5]. In addition, other arteries such as the radial artery (RA) [6, 7], and less commonly the right gastroepiploic artery (GEA) [8-10], and the inferior epigastric artery (IEA) [11-12] are used as bypass grafts. However, arterial grafts are relatively small arteries with a varying muscular component in the vessel wall and have a tendency to develop vasospasm during surgery, as discussed below in details.

Antispastic therapy therefore has been and remains an important issue through the history of development of CABG particularly in arterial grafting. Studies of the pathophysiology of spasm and the development of antispastic pharmacological management have paralleled the employment of arterial grafts in CABG [13-61]. This has included a large number of pharmacological and some non-pharmacological methods to prevent or treat vasospasm. Due to the complexity of the antispastic drugs and other methods involved, no single technique for antispastic management has been uniformly accepted or adopted. In this Review, we discuss the evidence base for the existence and incidence of vasospasm in CABG surgery using arterial grafts, the clinically available potential antispastic methods, and their possible advantages and disadvantages with a view to help elucidate mechanisms of vasospasm of arterial grafts and the decision making in choice of the potential antispastic methods.

Figure 1. The functional classification for arterial grafts, often referred as “HE classification” (From He GW: Arterial grafts for coronary artery bypass grafting: biological characteristics, functional classification, and clinical choice. *Ann Thorac Surg.* 1999;67:277-84. With permission).

1.1. Biological Characteristics and Clinical Classification of Arterial Grafts

The biological characteristics of arterial grafts are the basis of the behavior when they are grafted on the coronary artery system. A clinical classification is useful for a practicing surgeon. Based on our own experimental studies on the vasoreactivity combined with anatomical, physiological, and embryological considerations of the arterial grafts, I have proposed a functional classification for the grafts, suggesting that there are three types of arterial grafts: Type I- somatic arteries; Type II- splanchnic arteries; and Type III- limb arteries [29, 62]. The Type I arteries have better endothelial function and release more nitric oxide and other vasorelaxing factors [63, 64]; the Type II arteries, such as the gastro-epiploic artery, and the Type III arteries, such as the radial artery, have higher pharmacological reactivity to vasoconstrictors. The Type III arteries were later demonstrated to have higher contractility [65] and less eNOS expression [66]. This classification explains why the IMA has the best long-term patency. Because Type II and III arteries are prone to spasms due to higher contractility, they require more active pharmacological interventions.

2. PATHOPHYSIOLOGY OF SPASM

2.1. Existence and Incidence of Spasm of Arterial Grafts

Prevalence of Spasm of IMA

Spasm of IMA was first reported in 1987 [48]. Spasm could be a localized phenomenon or a diffuse process, referred to as a "string sign"[49], could cause hypoperfusion, typically occurring 30 to 40 minutes after discontinuation of cardiopulmonary bypass but also seen subsequently in the intensive care unit [50] when it may also be confused with coronary artery spasm. IMA spasm may also occur years after bypass grafting [51].

Based on these clinical observations, a large body of studies has been reported on the physiological and pharmacological characteristics of the IMA to understand the nature of spasm. In an early study, I demonstrated that the contractility of the distal section of the IMA is inversely correlated to its diameter; that is, the smaller the diameter, the greater the tendency for spasm to develop. This suggests that trimming off the distal end of the IMA as much as possible may be the best way to prevent graft spasm [52]. Nevertheless, since 1980s, a large body of literature has demonstrated the existence of spasm in IMA even in current practice [53-60].

The exact incidence of spasm of arterial grafts is unknown. This is particularly due to the fact that when it is mild, it may be asymptomatic; or, if responsible to vasodilator treatment, it is usually not reported. However, when spasm is severe and has little response to the usual pharmacological management, it can be lethal [53-57, 59]. A recent report indicated that among 5,762 patients who underwent isolated CABG, 7 patients (0.12%) experienced refractory spasm of coronary arteries and grafted conduits including the left IMA and 18 patients experienced perioperative vasospasm of a single coronary artery or of a grafted conduit [59]. This suggests that the confirmed severe perioperative vasospasm in coronary artery of grafts is about 0.43% in all CABG surgery. It is possible that the incidence of

vasospasm could be underestimated because there could be some patients who have vasospasm responsible to early use of vasodilator agents and not counted as vasospasm.

The Incidence of Spasm in Other Arterial Grafts

The RA and GEA have been demonstrated as prone to spasm. Dramatically, the revival of the use of RA was due to the use of successful antispastic management [6]. Since the more widespread use of the RA, spasm has been reported more frequently by cardiac surgeons [67], physicians [68] and cardiologists during catheterization [69]. Gabe and colleagues reported an unusual case of CABG, complicated by vasospasm of a grafted RA leading to postoperative ventricular fibrillation. RA graft spasm was demonstrated by angiography and was successfully resolved by intravenous nitroglycerin administration [70]. In addition, focal RA graft stenosis may be difficult to differentiate from spasm and can be treated by percutaneous intervention [71].

GEA spasm is also a well-recognized complication. Spasm can occur during or soon after harvesting of these vasoreactive grafts [72-74] or a few months or years postoperatively, as demonstrated by angiography [75].

There are fewer reports on IEA spasm. This is probably due to the fact that first, anatomically and functionally, IEA belongs to the Type I artery that may be less spastic [29, 62, 76] and second, use of IEA is not as frequent as IMA, RA, or GEA. However, occasionally, IEA graft is reported to have spasm even at 5-year angiographic follow-up [61].

2.2. Mechanisms of Spasm of Arterial Grafts

Despite of the efforts to try to understand the mechanism(s) of vascular spasm, it is still not fully understood owing to the complex nature at molecular levels. However, it is understood that spasm is an extreme form of vasoconstriction. In general, vasoconstriction may be evoked by a number of stimulants. Mechanical stimulation, nerve stimulation, as well as vasoconstrictor substances are common stimulants of vasoconstriction [17, 77]. These vasoconstrictor substances are therefore referred to as spasmogens. The possible spasmogens in arterial grafts have been well studied. These include: endothelium-derived contracting factors such as endothelin-1 [77, 78], prostaglandins such as TXA₂ or mimetics and PGF_{2 α} , α -adrenoceptor agonists such as norepinephrine, methoxamine and phenylephrine, platelet-derived substances such as 5-HT, and cellular membrane depolarizing agent potassium [77], mast cells and histamine [79]. It should be noted that studies have been performed in the human vessels since there are marked differences between human and animal vessels in response to these spasmogens [15, 17]. In addition, there are differences in responses between the IMA and coronary artery to vasoconstrictors [29]. In general, arterial grafts have higher responsiveness to norepinephrine because the coronary artery is α - and β -adrenoceptor-balanced vessel. However, IMA [19, 21, 80] and RA [37] are α -adrenoceptor predominant vessels. On the other hand, however, it has also been demonstrated that IMA graft is unresponsive to ergonovine at least in the amount required to produce coronary artery spasm in patients with variant angina [81]. In comparison to the IMA and IEA, the GEA has been demonstrated to have highest responsiveness to endothelin, TXA₂ mimetic, and potassium [29]. Subsequently, RA was demonstrated to have higher receptor-mediated contractility to endothelin and angiotensin II [65], vasopressin [82], 5-HT [83], and TXA₂ [84].

Other causes for vasospasm in arterial grafts may be related to certain pathways of vascular contractility or endothelial dysfunction. For example, autologous neutrophils release a stable non-protein small molecule that disturbs internal mammary artery endothelial function [85]. In addition, it was demonstrated that RhoA/Rho kinase pathway may be one mechanism by which RA is more susceptible to spasm than IMA [86] and that isoprostane responses in radial arteries are found to be mediated by prostanoid receptors selective for TXA₂ with activation of Rho-kinase and release of Ca²⁺ [87].

Recently, it has been recognized that fat cells or adipocytes produce large numbers of metabolically active substances with both endocrine and paracrine actions. Perivascular adipose tissue may play a role in the mechanism of vascular spasm [88].

Apart from vasoconstrictor spasmogens, other stimulants such as hypothermia [89] have also been demonstrated to be related to spasm of the grafts. Metabolic diseases such as diabetes mellitus have been demonstrated to increase the risk of radial artery spasm [67].

It must be indicated that the intact endothelium plays an extremely important role to prevent vascular spasm. The endothelium releases a number of endothelium-derived relaxing factors such as nitric oxide (NO), endothelium-derived hyperpolarizing factor, and PGI₂ [33, 34, 36] that keeps the adequate vascular tone in the arterial grafts. This is why it is ultimately important to prevent endothelial damage when using arterial grafts.

3. PHARMACOLOGICAL MANAGEMENT FOR SPASM (PHARMACOLOGICAL ANTISPASTIC METHODS)

Pharmacological studies have paralleled the development of the arterial grafts in CABG [17-28] owing to the fact that arterial grafts are relatively small arteries and there is a tendency to develop spasm in these arteries during surgery, as described above. Pharmacological studies on CABG grafts were initially focused on the IMA. Along with the increased use of other arterial grafts, studies have been also extended to these arteries. Pharmacological management in CABG is a complex topic. It should actually include two aspects. This may involve firstly, systematic use of pharmacological agents in order to maintain cardiac output and graft function during the pre-, intra-, and post-operative period, and secondly, specific pharmacological management for arterial conduits by using both systematic and topical methods.

Adequate understanding of the mechanism of vasoconstriction and the effect of vasodilators is essential to design any protocols to use vasodilators. Such understanding should be based on 1). the nature of vasoconstriction and the mechanism of the vasodilators [77]; 2). the status of the contraction that refers to prevent or to reverse existing contraction/spasm [17]; 3). duration of the use of a vasodilator agent, which refers to single or long-term use; the latter may develop tolerance such as to nitrates [90]. The role of mitochondrial aldehyde dehydrogenase was discovered [90], which specifically generates 1,2-glyceryl dinitrate from nitroglycerin, in the bioactivation of nitroglycerin to elicit vasorelaxation and in the development of tolerance to nitroglycerin; 4). the concentration of vasodilator that should be correlated to the plasma concentrations if used systematically but could be much higher if used topically [17]; and 5). the rapidity of onset of effect that may maximally relieve spasm [14, 24].

3.1. The Vasodilator Agents Used for Arterial Grafts

Papaverine

Papaverine is a traditional topical vasodilator and is probably a pharmacological vasodilator used earlier than most others. The satisfactory results were reported in early studies [91]. Papaverine is an opioid-derivative and a non-specific vasodilator substance, which relaxes blood vessels through multiple mechanisms. It is a phosphodiesterase inhibitor and therefore may raise cGMP level in smooth muscle cells [92]. Papaverine-induced relaxation is also due to other actions such as decreased calcium influx [93], or inhibition of release of intracellularly stored calcium [94]. It usually relaxes vessels (such as human IMA) at high concentrations regardless of the nature of the contraction. It has been suggested that papaverine has a satisfactory vasorelaxant effect in IMA [91, 95-100] and other arterial grafts [101]. However, papaverine is not recommended for systemic use. The major concern of the topical use of papaverine is its acidic nature (pH 4.4 at $-2.6 \log M$ and pH 4.8 at $-4.5 \log M$ [23], which may damage the endothelial function. These concentrations are related to the solutions used for surgery as demonstrated in the human RA [36]. A common clinical protocol to topically use papaverine is to mix papaverine with blood. This may reduce its acidity due to the buffering effect of blood. On the other hand, papaverine hydrochloride is relatively unstable in non-acidic solutions and a white precipitate sometimes formed when papaverine is added to plasmalyte solution (pH approximately 7.4) [13] and the effect of this phenomenon in papaverine-blood mixture is unknown. In addition, the onset of vasodilation effect of papaverine is slower than other vasodilators such as NTG and verapamil although once reaches the plateau, the effect of papaverine is sustained [23, 34]. Papaverine was also shown to be inferior to nitroglycerin in GEA [102].

Nitrovasodilators

Organic nitrates (nitrovasodilators) such as nitroglycerin (NTG, i.e., glyceryl trinitrate [GTN]), sodium nitroprusside (SNP), or isosorbide dinitrate are widely used in CABG patients. The mechanism of vasorelaxation of these vasodilators is that they release NO, a powerful stimulant for guanylate cyclase which raises cGMP in the smooth muscle cell [103]. This subsequently reduces intracellular calcium concentrations and leads to relaxation of the smooth muscle cell.

Nitrovasodilators (NTG or SNP) have been demonstrated to be potent vasodilators in the human IMA [17, 20, 23, 25, 33, 41, 42, 44, 45, 47, 104-109], RA [36, 38, 41, 42, 44, 45, 106-108, 110], GEA [40, 105], and IEA [30, 106]. It was demonstrated that NTG is effective for either topical [19, 42, 102, 109, 110] or systemic [42, 44, 107] use. Nitrates are slightly more effective in blocking receptor-operated channels than blocking depolarizing agent-mediated contraction [17]. Early studies focusing on NTG and nitroprusside showed different effects of these drugs in vitro and in vivo [104]. Another group of NO donors thionitrites such as S-nitrosothiol RIG200 has been demonstrated to have prolonged, NO-mediated relaxation [111].

Importantly, nitrates are effective in treating established vascular spasm, regardless of the nature of the contraction; i.e., they are effective in reversing either receptor-mediated (TXA₂ receptors, adrenoceptors, or ET receptors) contraction or depolarizing agent (K⁺)-mediated contraction [17]. However, they are less potent in prevention of vasospasm [17, 19, 20, 38].

This is probably related to the tolerance of a vessel to these nitrovasodilators [19, 25, 90, 103], as demonstrated later that mitochondrial aldehyde dehydrogenase plays a role in the mechanism of the development of tolerance to nitroglycerin [90]. Compared each other, NTG is more potent than SNP in the vasorelaxing effect but SNP is more effective in preventing ANGII and α -adrenoceptor-mediated contraction in the IMA [35].

Calcium Antagonists

Classical calcium antagonists were three chemically divergent groups - dihydropyridine (nifedipine, exc.), phenylalkylamines (verapamil, exc.), and benzothiazepines (diltiazem, exc.). The new generations of these drugs, particularly the new dihydropyridines such as nisoldipine [112], nicardipine [113-116], amlodipine [117], cilnidipine [118], and azalnidipine [119], have been developed in the past decades and their effect on arterial grafts have been investigated. In general, they all express vasodilatory effect in arterial grafts. In addition to the calcium channel blockage, some of these new generations of calcium antagonists such as amlodipine [117], cilnidipine [118], and azalnidipine [119] may also stimulate the vascular endothelium to release NO that may further enhance the vasorelaxant effect in arterial grafts. It is possible that these new vasodilators may be proved to be usefull in the prevention of spasm in arterial grafts.

In fact, calcium antagonists have been used as antispastic drugs in arterial grafting either alone [6, 120] or in combination to NTG [23, 34, 36, 39, 121]. Among the first generation of the three calcium antagonists, it was reported that diltiazem is the least potent one and nifedipine is 15-fold more potent than diltiazem in IMA [17]. However, diltiazem contributed to the successful revival of the RA after this graft was abandoned for almost 20-years due to serious spasm problems [6]. In contrast, diltiazem was reported to have little effect on human RA contractions [38, 43]. Further, verapamil is more potent than diltiazem in the human vessels [17] and this drug was available in injection form, therefore it was recommended to be included in the antispastic protocols [23, 34, 36]. As discussed before, in arterial grafts the effects of vasodilators depend on the nature of the vasoconstriction and this is particularly important for calcium antagonists. When IMA contracts with depolarizing agent potassium (K^+), nifedipine or other calcium antagonists are very effective in both preventing and reversing IMA contraction through inhibition of L-type calcium channel [17]. This is due to the fact that calcium antagonists relax blood vessels through a specific mechanism. Calcium antagonists reduce Ca^{2+} influx by blocking voltage-operated calcium channels, which is the major mechanism for the depolarizing agent K^+ to contract vessels. Therefore, calcium antagonists are particularly effective in preventing or treating K^+ -induced contraction and this has been demonstrated in either IMA [17, 39] or RA [38, 43]. However, calcium antagonists such as nifedipine are less effective in contraction mediated by receptors such as TXA_2 receptors [17], α -adrenoceptors [27 122], ET [25, 123], or vasopressin (VP1 receptors) - mediated contraction [124].

Phosphodiesterase (PDE) Inhibitors

As modulators of vascular smooth muscle tone, intracellular cAMP and cGMP are controlled through synthesis by cyclases and through hydrolysis by PDEs that are classified to at least five types. PDE III inhibitors such as amrinone or milrinone are known to inhibit cGMP-inhibitable low K_m cAMP PDE [125]. The cardiac and vascular smooth muscle

actions are favorable in postoperative management of patients who undergo open heart surgery, particularly in patients who present ventricular dysfunction and receive arterial grafts for CABG. The effect of PDEIII inhibitor milrinone on the IMA [33, 126, 127] or RA [82, 128, 129], and PDEIIIA inhibitor olprinone on the GEA and RA [130] has been studied and shown effective. It is noticed that the effect of milrinone on the IMA is superior to that on RA [82]. Further, in the systemic use, after cardiopulmonary bypass, milrinone dilates the IMA [131] and perioperative continuous infusion of milrinone, compared with nifedipine, results in a significantly lower incidence of myocardial ischaemia and myocardial cell damage after elective CABG [132]. In opposite, another PDEIII inhibitor enoximone is a potent in vitro vasodilator but exerts weak relaxant effects in IMA and GEA at concentrations in the therapeutic range [133].

α -adrenoceptor Antagonists

It has been demonstrated that both IMA [21, 134] and RA [37, 134] are α_1 -adrenoceptor-predominant artery. However, IMA has little α_2 -adrenoceptor [21] whereas the RA has significant α_2 -adrenoceptor [37] function, although the RA is also α_1 -adrenoceptor predominant. This is the rationale to use α -adrenoceptor antagonists such as phenoxybenzamine as antispastic drug in CABG as an effective agent to prevent catecholamine-mediated spasm of RA [135, 136].

Phenoxybenzamine is reported more effective and less harmful than papaverine in the prevention of radial artery vasospasm [137, 138]. On the other hand, however, theoretically, α -adrenoceptor antagonists are only effective in reversing the contraction evoked by α -adrenoceptor but not to other vasoconstrictors as may be predicted from the pharmacological mechanism of α -adrenoceptor antagonists, i.e., α -adrenoceptor antagonists may only be effective in one specific mechanism of spasm and could be insufficient when the spasm is due to other mechanisms such as due to other receptor-mechanisms or due to the mechanism related to the L-type calcium channels. The nature of vasoconstriction and spasm is complex and may involve many other vasoconstrictors [77]. In fact, Conant and colleagues [139] reported that phenoxybenzamine-treated radial artery failed to respond to noradrenaline but did respond to vasopressin, angiotensin II, endothelin-1, and KCl and therefore is insufficient to prevent spasm in the radial artery. In this regard, new calcium antagonists with α_1 -adrenergic receptor blocking activity such as AJ-2615 may overcome the shortage of pure α -adrenoceptor antagonists [140] but this requires more clinical studies.

Beta-Receptor Agonists

It has been reported that β -adrenoceptor function is weak in both IMA [80] and RA [37], despite of the coexistence of at least three distinct beta-adrenoceptors in IMA [141]. Therefore, theoretically, use of β -adrenoceptor agonists such as dobutamine unlikely relaxes the IMA and RA to a significant degree and this was demonstrated to be true in IMA and GEA [133].

Dopamine Receptor Agonists

The effect for these agonists is more complicated. Due to the complexity of the interaction between dopamine and dopamine receptors as well as α_1 -adrenoceptors, dopamine-induced responses are complex and dose-dependent [142]. In RA, dopamine

enhanced the norepinephrine-induced contraction. In GEA, low concentrations ($<10^{-7}$ mol/L) of dopamine attenuated the norepinephrine-induced contraction but higher concentrations did not. In IMA, dopamine induced a vasorelaxation on the norepinephrine-contraction only at higher concentrations (10^{-6} - 10^{-5} mol/L) [142] and the selective dopamine-1 (D1) receptor partial agonist fenoldopam, 0.1 microg/kg/min, did not influence coronary conduit blood flow to a clinically significant extent [143]. Most likely, dopamine is not suitable to be used primarily for the vasorelaxant effect in the arterial grafts but its effect on the graft should be aware of when it is used primarily for its inotropic effect.

Prostacyclin PGI₂ Analogue

Synthetic analogue of prostacyclin PGI₂ iloprost was recommended to be an antispastic drug for RA [144, 145] and IMA [145]. Iloprost, when the infusion was initiated 5 days before surgery, was shown to have superior efficacy over diltiazem in preventing RA spasm in the early period and the 2-year angiographic patency [146].

Rho-Kinase Inhibitor

Rho kinase inhibitors may be effective drug candidates to prevent and treat spasm [147]. Intraluminal injection of rho kinase inhibitor fasudil (1.5 mg/min for 15 minutes) into the spastic arteries (both coronary and graft arteries) successfully resolved the spasm and improved myocardial ischemia in all patients without any systemic adverse effects [148]. In addition, recently, fasudil is shown to be useful for dilating RA grafts [149].

Angiotensin Receptor Antagonist

Due to the fact that angiotensin has been shown to be a spasmogen in arterial grafts [65, 67, 83, 113]. Angiotensin receptor antagonists were therefore tested for the possible antispastic effectiveness [150]. However, there are no clinical reports yet.

Heme Oxygenase 1

Heme oxygenase plays a role in the control of arterial vasoreactivity [151]. Hemin caused in vitro induction of heme oxygenase 1 in human IMA and RA and resulted in a reduced contractility to norepinephrine, partially through the cyclic guanosine monophosphate-dependent pathway [151]. It is possible that activation of heme oxygenase may become one of the antispastic methods.

C-Type Natriuretic Peptide

C-type natriuretic peptide relaxes IMA and RA precontracted by endothelin-1 and therefore may have therapeutic potential of antispastic therapy [152].

TXA₂ Antagonists

Because of the well-known importance of TXA₂ in vasoconstriction and thrombosis, specific TXA₂ antagonists may be useful in the antispastic therapy of arterial grafts. One of TXA₂ antagonists GR32191 has been found to be a potent vasodilator for TXA₂-mediated contraction in either IMA [153] or RA [154]. Further clinical trials are necessary to confirm this.

Vascular Endothelial Growth Factor (VEGF)

As an endothelium-dependent relaxing agent, VEGF may not be considered as the primary drug for antispastic therapy in arterial grafts. However, the potent hypotensive effect of VEGF due to its systemic vasorelaxation through endothelium-dependent mechanism is demonstrated in the IMA [155]. Most likely, the relaxing effect is related to the NO and PGI₂ mechanisms through the KDR-receptor [156].

Potassium (K⁺) Channel Openers (KCOs)

ATP-sensitive potassium channels (KATP) exist in a wide range of cells, particularly in endocrine cells, smooth muscle, skeletal muscle, neurons, and cardiac cells [157]. Potassium (K⁺) channel openers (KCOs) are considered to comprise a heterogeneous group of organic compounds [158]. KCOs repolarize or hyperpolarize the cell membrane. They therefore decrease the opening probability of voltage-dependent L- and T-type Ca²⁺-channels and restrain agonist-induced Ca²⁺ release from intracellular sources through inhibition of inositol trisphosphate (IP₃) formation, and lower the efficiency of calcium as an activator of contractile proteins [158]. In addition, KCOs may accelerate the clearance of intracellular free Ca²⁺ via the Na⁺/Ca²⁺ exchange pathway. The effects drive the vascular smooth muscle cells into a relaxed state and reduce membrane excitability and the reactivity of the cell [158]. It has been suggested that vascular smooth muscle is particularly sensitive to KCOs [157]. Considering these characteristics, KCOs are of great value as therapeutical agents. Aprikalim [159, 160], levcromakalim [161, 162], KRN4884 [163], and rilmakalim [162] have been studied in the human IMA and found to be potent vasodilators in a number of receptor-mediated contraction and therefore, these KCOs may become a clinically useful antispastic drug in arterial grafts.

Antiplatelet Drugs

Activated platelets induce pronounced contraction of the gastroepiploic artery that may contribute to postoperative spasm. Therefore vasodilators that prevent the effects of TXA₂ and serotonin may be beneficial to gastroepiploic artery graft function [164].

Vasodilators through Other Mechanisms Potentially Useful for Antispastic Protocols

A few of other substances have been investigated in the human arterial grafts and suggested be potential antispastic agents. Nutritional supplement L-carnitine Carnitine, a quaternary ammonium compound biosynthesized from the amino acids lysine and methionine, is widely available as a nutritional supplement. L-carnitine is a potential vasodilatory drug for internal mammary artery and saphenous vein grafts [165]. Botulinum toxin inhibits muscle contraction for about three months and is shown to prevented arterial graft spasm in vitro and had a longer lasting effect than papaverine, with no toxic effect on the artery of rats [166] but there were no human artery studies. Finally, NO-independent soluble guanylate cyclase (sGC) activator YC-1, and DEA/NO (diethylamine/nitric oxide), a NO-nucleophile adduct may be effective as vasodilator for the short-term treatment of perioperative spasm of coronary bypass grafts [167]. Most likely, those vasodilator substances would unlikely be primarily chosen as clinical antispastic agents.

Combination of Vasodilators

It must be emphasized that all vasodilators have their own limitations in some aspect because each of them has a specific mechanism or mechanisms to relax vessels. These mechanisms have been discussed above. Combination of these vasodilators may overcome these disadvantages and therefore produce a better effect. Some of the combinations have been studied in the IMA and RA. For example, as an intraluminal or topical solution for the preparation of the grafts, calcium antagonists and NTG may have synergistic effect in IMA [23, 39, 112, 168] and in RA [34, 36 22, 23; 121, 169]. Yoshizaki and associates have demonstrated that combination of verapamil and nitroglycerin improves the patency rate of radial artery grafts [169]. Even in the critical situation with lethal spasm problems, the combination of NTG and verapamil has been reported to successfully release the spasm in arterial grafts through intraluminal injection that was a life salvage procedure [54]. The method is used successfully by others to relieve the coronary spasm as well [170] and is now used in catheterization laboratory for preventing RA spasm with success [171].

Other combination of vasodilators may also be clinically useful. The more than additive effect of milrinone and NTG has also been demonstrated [33] although such in vivo effect is to be demonstrated [46]. In addition, combined use of enoximone (a PDEIII inhibitor) and dobutamine (a beta-receptor agonist) at concentrations in the therapeutic range exerts a greater than additive vasorelaxant effect in IMA and GEA [133]. However, the role of such combination of vasodilator drugs in preparation of arterial grafts is to be established.

Taken together, from literature, the effect of a particular vasodilator in prevention or treatment of spasm in arterial grafts is often contradictory. We may conclude that there is no “perfect” vasodilator for dilating the IMA or other arterial grafts. This is due to the fact that spasm of arterial grafts may involve many mechanisms and each particular vasodilator may only relax the vessel through one mechanism or sometimes more than one mechanisms but no vasodilator may relax the vessel through all mechanisms. Under some circumstances, combination of vasodilators may be preferable.

3.2. Existing Pharmacological Methods (Antispastic Protocols) to Overcome Spasm

There are various antispastic protocols available in different units around the world.

Pharmacological methods are the most common antispastic protocols used in clinical practice world-widely.

Table 1 gives summary of the pharmacological antispastic protocols used in the practice of arterial grafting. Some of the protocols were designed based on the pharmacological studies on arterial grafts, as detailed in Table 1. However, other protocols are rather empirical.

Table 1. Summary of the antispastic protocols and existing techniques used in arterial grafting in CABG (from reference 202 with permission)

Authors	Topical	IMA	GEA	RA	Systemic	Postoperative oral

4. NON-PHARMACOLOGICAL THERAPY TO OVERCOME SPASM

4.1. Denervation or Skeletonization or En-Bloc Harvesting?

It has been suggested that skeletonized arterial grafting may reduce the risk of graft spasm and may improve graft patency [172] and the removal of the periarterial sympathetic nerve from the human gastroepiploic artery reduced vascular contraction, elicited by peripheral nerve stimulation, without disturbing endothelial and smooth muscle contractile functions. This reduction may contribute to the prevention of vasospasms [10].

Similarly, it was reported that the results of using skeletonized radial artery grafts are excellent [130, 173-175] and this is often done with the ultrasonic scalpel [173, 174]. Kucukarslan and colleagues [176] used long fasciotomy of the posterior aspect of the RA for the purpose of sympathectomy to prepare the RA graft and believed this technique provides a satisfactory increase in the blood flow index and reduces the manipulation time as well as the risk of injury to the graft.

On the other hand, a study from Germany compared the skeletonization technique with pedicle preparation using either an ultrasonic scalpel or scissors and analyzed endothelial morphology by scanning electron microscopy and the conclusion is that skeletonization with an ultrasonic scalpel did not result in additional length and was more frequently associated with severe endothelial damage. Pedicle preparation using scissors or an ultrasonic scalpel is much simpler and faster, and does not jeopardize endothelial integrity [177]. Therefore, whether the skeletonization technique gives better results is still in debate.

In support of the above study, en-bloc free gastroepiploic artery graft, which has the gastroepiploic vein anastomosed to the right atrial appendage to prevent graft spasm [178] is proposed. They believed that the free gastroepiploic artery grafting with venous drainage technique can prevent graft spasm, leading to improved patency rate.

A retrospective review [179] in 57 patients who received en-bloc grafts and 29 who had skeletonized grafts reveals that 80-month patency rates of 100% for en-bloc grafts and 60% for skeletonized grafts. The observation, however, requires further clinical trials to be confirmed.

4.2. Carbon Dioxide Insufflation

Carbon dioxide insufflation of the internal thoracic artery was suggested to be an efficient technique to increase the flow and prevent vasospasm [180]. The reactivity of the human internal mammary artery grafts harvested by either classical or carbon dioxide insufflation technique was compared; carbon dioxide insufflation technique does seem not only to protect the integrity of the endothelium and the whole vessel, but also prevent the possible vasospasm of the internal mammary artery segments [181].

4.3. Normothermia or Heat Therapy or No Need for Vasodilators

Normothermia

It is possible that hypothermia plays an important role in radial artery vasospasm. It was even proposed that after harvesting the graft, regaining physiological normothermic state is enough for vasodilatation [182]. It has been suggested by the same group that preserving internal thoracic artery pedicles in normothermic conditions can be the preferred treatment for spasms [183] and that store of the radial artery graft in normothermic bath may relieve spasm of radial artery and the effect is similar to the use of verapamil-nitroglycerin solution [184]. On opposite, it was also proposed to treat radial artery grafts thermally in situ (45°C to 65°C; up to 120 s), so-called thermal ablation with effective anti-spastic effect [185].

However, the concept in those sporadic reports has not been widely accepted.

As mentioned above, the causes and mechanisms of vasospasm involve multiple factors, unlikely the temperature is the only factor affecting the vascular contraction/relaxation balance and therefore it is unlikely true that to use normothermia as the anti-spastic method would be effective under all situations.

4.4. Injection of Room Air Beneath the Endothoracic Fascia Before IMA Dissection

Occasionally, injection of room air beneath the endothoracic fascia before IMA dissection is used to prevent spasm and shorten harvest time [186] but the practice is not widely accepted.

4.5. Harmonic Scalpel

Since causes of vasospasm of the grafts may involve thermal injury caused by electrocautery and traumatic harvesting technique, the harmonic scalpel was proposed to decrease the harvesting time, frequency of spasm, and excessive use of hemostatic clips [187].

This technique was rapidly spread out and was demonstrated to be effective in harvesting of the RA associated with decreased RA spasm, good hemostasis, no additional harvest time, and has become standard technique in a number of units [188-193]. In addition, it was demonstrated that the optical coherence tomographic findings suggest that the harmonic scalpel induces less spasm and intimal injury compared with electrocautery [194].

4.6. Intraoperative Detection of Intimal Lipid in the Radial Artery Predicts Degree of Postoperative Spasm

In two reports from one group [195, 196], optical coherence tomography imaging was used as a quality assurance tool for evaluating endoscopic harvest of the radial artery and the authors imaged RA conduits before and after CABG in order to characterize intimal

abnormalities that might be related to the risk of spasm. They reported that the degree of attenuation of the optical coherence tomography (OCT) signal produced by the RA was strongly correlated with percentage diameter change and was significantly more pronounced in grafts with spasm versus no spasm. Histology confirmed lipid deposits in areas of RA with strong attenuation. RA conduits were often found by OCT imaging to have a substantial amount of lipid, which in turn strongly relates to the risk of postoperative spasm. Screening conduits based on characteristics of intimal quality may improve results following RA grafting [195] and catheter-based OCT provide an important quality assurance tool for RA harvest [196].

4.7. Careful Dissection and Preparation of the IMA Pedicle to Prevent Injury and Spasm

Tector and colleagues [197] emphasize that initial flow in the IMA immediately after grafting is critical to the success of the operation. Careful dissection and preparation of the IMA pedicle to prevent injury and spasm, constructing parallel and perpendicular anastomoses so the most proximal portion of the IMA is used for anastomosis and the use of the free right IMA to increase length of graft available are measures employed to increase critical flow.

4.8. Intractable LIMA Spasm in the Postoperative Period Treated by Placement of 'Bridging' Stent - A "Hybrid Procedure"

Pratt and colleagues [57] reported that a woman with critical left main stenosis suffered intractable left internal mammary artery (LIMA) spasm post-coronary artery bypass grafting. This was managed with a left main stent and the patient stabilized. A 3-month follow-up angiogram showed a patent graft and a blocked stent. This "hybrid" method may be the choice of the patients under such circumstances.

4.9. Pre-Emptive Stellate Ganglion Block

Pre-emptive stellate ganglion block (SGB) was suggested to be an effective method for increasing radial artery blood flow and preventing radial artery spasm [198].

4.10. Extrafascially Harvested Radial Artery

It was suggested that when the radial artery is harvested extrafascially, with diltiazem infusion, the RA may be used with improve the early and long-term results [199].

4.11. Injection of Vasodilators into Arterial Grafts through Cardiac Catheter to Relieve Spasm

When the grafts or the coronary artery develop spasm perioperatively, injection of vasodilators such as verapamil plus nitroglycerin into arterial grafts as well as the native coronary artery through cardiac catheter may relieve spasm and this could be a life-saving procedure [54]. The method is used successfully by others to relieve the coronary spasm as well [170]. Due to the fact that radial artery spasm is a frequent complication of the transradial approach for coronary angiography and angioplasty, this method is now used in catheterization laboratory. Administration of an intra-arterial vasodilating cocktail composed of verapamil plus nitroglycerine prior to sheath insertion reduces the occurrence and severity of radial artery spasm [171].

4.12. Balloon Calibration to Relieve IMA Spasm

This technique allows full IMA distention without the devascularizing effects of full skeletonization and was applied in more than 793 patients over five years. Postcalibration flow rates increased 3- to 18-fold over precalibration flow rates [200].

4.13. Adenoviral Transfer of NOS

Adenoviral transfer of NOS suggests that future clinical application of gene therapy may play an important role in prevention of RA vasospasm [38].

4.14. Extracorporeal Membrane Oxygenation (ECMO)

For diffuse refractory vascular spasm after CABG, a rare but lethal condition, an aggressive treatment, that is, prompt ECMO institution and controlled cardiocirculatory assistance, represents the preferred solution to face such a dramatic event and may save patient lives [59].

The above pharmacological and non-pharmacological antispastic methods have been summarized with detailed illustrations and tables in the two most recent review articles [201,202].

SUMMARY AND CONCLUSION

CABG surgery has been the standard treatment for patients with coronary artery disease particularly for three-vessel disease, although PCI has become the preferred method in one- or two-vessel disease. Arterial grafting using autologous arteries as the grafts has been demonstrated to have superior long-term results. Use of the left IMA to graft the diseased LAD has become the standard method for almost all CABG surgery and bilateral IMA grafts

may further enhance survival over the long-term. Other arteries such as radial artery, right gastroepiploic artery, and inferior epigastric artery are commonly used arterial grafts. However, in comparison to vein grafts, arterial grafts have a tendency to develop vasospasm that can lead to potentially life-threatening complications. This is a long-recognized clinical problem and occurs even in the current practice. There have been various antispastic protocols, either pharmacological or non-pharmacological, but the rationale and efficacy are sometimes unclear. The multiple methods used in CABG to prevent and treat spasm of arterial grafts are effective in the current practice but it is still controversial as to what is the most effective regimen. This is partially due to the pathophysiological complexity of the mechanism of vascular spasm and the evolution of pharmacological vasodilators and non-pharmacological methods. Better understanding of the mechanism of vascular spasm, development of new pharmacological vasodilators, and the adequate evaluation of non-pharmacological methods may lead to a more unanimous opinion as to the best method to prevent and treat arterial spasm in contemporary clinical practice.

FUNDING SOURCES

The work described in this paper was fully supported by grants from the National Natural Science Foundation of China (81170148), Zhejiang Provincial Natural Science Foundation (LY15H020008), Hangzhou Science and Technology Projects (20140633B12), & Tianjin Binhai Key Platform for Creative Research Program (2012-BH110004), Binhai New Area Health Bureau (2012BWKZ 008).

DISCLOSURES

None.

ABSTRACT

The transvenous route is the choice treatment for Cardiac resynchronization therapy (CRT). The success of implant technique during ventricular resynchronization therapy is related to the better left ventricle (LV) lead placement, such as pacing lead performance and stability, and in absence of phrenic nerve stimulation. The cardiac venous anatomy may still limit implantation of transvenous LV leads. Limitations to reach the best LV target area by percutaneous catheterization, and all cases of transvenous lead implantation failure, may be surmounted by direct surgic epicardial LV implant on the lateral or posterolateral wall. Surgical implantation of the LV electrode takes shorter time and involves no radiation as compared to transvenous route. During last decades, surgical approach has become more and more less invasive and evolved, with shorter implant duration time and important reduction in peri-operative complications. In this chapter we will discuss about surgical approach techniques and peri operative complication rate. More over in this chapter, we summarized the most utilized surgical approaches to LV pacing lead implant.

Keywords: cardiac resynchronization therapy, sternotomy, thoracotomy, video assisted thoroscopic techniques and robotic surgery

INTRODUCTION

Cardiac resynchronization therapy (CRT) is a choice treatment for patients with severe cardiac failure refractory to medical drug therapy and with evidence of electromechanical dyssynchrony [1].

Several multicentre trials have shown that CRT via the transvenous route is the choice treatment to have significant improvements in exercise capacity, functional class, peak VO₂, and mortality [2].

The coronary venous anatomy has great interpersonal variation, which may result in the inability to reach an acceptable and stable left ventricle (LV) lead position [3]. The final position of the LV pacing lead depends on coronary sinus anatomy, pacing lead performance and stability, and on the absence of phrenic nerve stimulation [4]. An optimal left ventricle lead position may theoretically be defined by the positioning of the LV pacing lead coincident with the latest activated LV areas [2, 3]. In clinical practice, the standard first-line approach is the trans venous epicardial LV lead placement through a side lateral, postero-lateral (and/or antero-lateral) branch of the coronary sinus (CS) [4]. Successful implantation, may depend on the inclusion criteria, as mechanical dyssynchrony and latest mechanical activation by TDI measurements [5].

The success of implant technique during cardiac resynchronization therapy, is related to the better LV lead placement, such as pacing lead performance and stability, in absence of phrenic nerve stimulation [4]. Therefore the postero-basal LV wall pacing provides more effective hemodynamic augmentation (than either lateral or anterior positioned leads) [6], but it is related to a rate of unsuccessful transvenous LV lead implantation about 8% - 12% [7]. In fact, despite technological and procedural improvement, cardiac venous anatomy may still limit implantation of transvenous LV leads [8]. After a successful CRT implant, the left ventricular lead dislodgment (about 6% to 14%), and the increased pacing threshold, may require an re- intervention in a percentage of 13% to 18% of patients [9]. Sometimes, there are no tributaries found in the CS, just a small part of the entry of the target vein, and too small side branches or complete absence of the side branches, requiring a coronary venoplasty or stenting [10]. Limitations to reach the best LV target area by percutaneous catheterization, and all cases of transvenous lead implantation failure, may be surmounted by direct surgic epicardial LV implant on the lateral or posterolateral wall [11]. Surgical implantation of the LV electrode takes shorter time and involves no radiation when compared to transvenous route [11].

The surger approach is related to the direct visualization and positioning of the lead at the obtuse marginal branch area [11]. Concerns persist regarding peri-operative morbidity and long recovery times, related to higher rates of post-operative respiratory tract infections, transient renal dysfunction, and pericardial effusions [12]. This higher complication rate combined with the recovery from a general anaesthetic, led to an increased length of hospitalization as compared to the transvenous group [12]. In this chapter we will describe the CRT surgical indications and techniques.

METHODS

In this chapter we report surgical techniques to perform surgical CRT. The open chest access remains secondary choice to standard endovascular lead placement failure [12]. Surgically epicardial LV implant leaves operators free to choose the optimal LV stimulation site [12]. Surgical CRT approaches may be classified on the basis of the LV pacing site (epicardial versus endocardial), and on the basis of operative access used (open chest orthoroscopic/robotic access) [13-16], table 1. Surgical approaches shown the direct visual of target LV wall, giving the opportunity to choose the lead-tip position [13-16]. These approaches are combined to a low risk of lead dislodgement and phrenic nerve stimulation, and there is not the limitation of the coronary sinus anatomy [13-16]. Less fluoroscopy and avoidance of intravenous contrast material are also benefits over conventional percutaneous CRT [11-16]. Surgical epicardial left ventricular lead placement has several disadvantages, as the need for general anesthesia, the presence of poor vision due to epicardial fat or the presence of adhesions, and it is more invasive than the transvenous approaches [11-16].

The surgical trauma requires higher recovery time, compared with the transvenous left ventricular lead implantation, and surgical implanted epicardial leads have a significantly higher failure rate [11-16]. Epicardial pacing lead implantation is the currently preferred surgical alternative for left ventricular lead placement [11-16]. In table 1, we summarized the most utilized surgical approaches to LV pacing lead implant (*median sternotomy, lower ministernotomy, full left thoracotomy, minimal thoracotomy (minithoracotomy), video assisted thoracoscopic techniques and robotic surgery*).

Median Sternotomy

This surgical approach gives to operators a full access to cardiac left ventricle epicardial anatomy, selecting the target LV area to reach the optimal LV segment to pace [11-16]. On other hand, today this surgical access is used only whenever another cardiac surgery procedure is planned in a patient with reduced left ventricular function and with indication to CRT therapy [11-16]. For this reason we report a short description about this technique, and a representation in figure 1.

Table 1. In this table representation of surgical pacing site, surgical approach, and technique

Pacing site	Surgical approach	Mini invasive surgical approach	Surgical technique
Epicardial	Thoracotomy, Sternotomy	Mini thoracotomy	VAT
Endocardial	Trans-septal	Transapical Endocardial LV Lead Implantation	Transarterial Endocardial LV Lead Implantation

VAT is for video-assisted thoraco scopic; LV: left ventricle.

Figure 1. Median sternotomy representation. In this figure the chest, with ribs and sternum. The red discontinuous line is indicating the surgical approach to have a full median sternotomy.

Lateral Thoracotomy

Lateral thoracotomy allows direct visualization of the anterior and lateral segments of the left ventricle epicardium, thereby enabling a perfect selection of a pacing site free from coronary vessels and distant from the phrenic nerve [16].

This approach achieves relatively anterior lead placement that may be ineffective in ventricular resynchronization [12, 16]. A small thoracic size, the presence of a severe cardiomegaly, and/or the presence of adhesions may restrict the safe manipulation of surgical instruments [16]. After standard single-lumen intubation, with the left lung excluded from ventilation and the right lung selectively ventilated, the patient is placed in supine position with the left chest elevated 30–40° [16]. About the operative technique, a large lateral thoracotomy between intercostal space 4–5 is performed [16], and the pericardium is opened anterior to the phrenic nerve and fixed with traction-sutures to the skin, rotating the heart to the right and creating optimal exposure of the lateral surface.

Unipolar or bipolar epicardial can this way easily be attached to the target area and secured with two polypropylene 5-0 or 6-0 sutures [16]. The connector of the lead can be brought through the third intercostal space and submuscularly tunneled to the device pocket and the pacemaker [16]. After this, the pericardium can be partially closed, and the insertion of a pleural drain and the standard wound closure complete the procedure [16].

Left Mini-Thoracotomy

The procedure is performed following a 4-5 cm long mini-thoracotomy in left lateral, mid axillary position at the site of the fourth intercostal space, the left lung is pushed back with a wet towel [16], figure 2. The pericardium is opened anterior to the phrenic nerve, and fixed with hang sutures to the skin with the heart rotated to the right to create optimal exposure to the lateral surface [16].

Figure 2. In this figure representation of lateral mini- thoracotomy. As indicated by red discontinuous line, the approach is by 3rd and 4th intercostal space. In this position, an epicardial lead can be easily attached to the left ventricle target area.

In this position, an epicardial lead can be easily attached to the target area [16]. Completing the threshold measurements, the lead is secured with two sutures [16]. The connector is sub muscularly tunneled to the device pocket and connected to the pacemaker [16]. The pericardium can be approximated, and a pleural drain is placed and the wounds are closed as usual in layers with absorbable sutures [16].

Video-Assisted Thoracoscopic Left Ventricular Pacing

Video assisted thoracoscopic technique for lead implantation is less invasive than standard thoracotomy, and can allow more posterior lead placement [16]. The use of thoracoscopy can allow a safer procedure than left mini-thoracotomy, warranting better exposure and perfect control of the pacing site and reduced surgical trauma [17]. This approach is practiced under general anesthesia, and the patient is intubated with a double-lumen endotracheal tube, with the left lung excluded from ventilation and the right lung selectively ventilated [16, 17]. The patient is placed supine on the operative table, with a longitudinal support under the left side of the back and some degree of table tilt to the right [16, 17]. Three ports are used as standard access to the left ventricle [16, 17].

Figure 3. The first is positioned in the mid-axillary line, in the third or fourth intercostal space, for the insertion of the thoracoscope, a second port is placed inferior to this in the fourth or fifth intercostal space, and a third port is placed anteriorly in the fourth or fifth intercostal space [16, 17], figure 3. After visualization of the pericardium in the camera and his freeing from fat, the pericardium is longitudinally opened, anterior to the phrenic nerve, to expose the left ventricular free wall [16, 17]. An epicardial lead is placed into an unscarred area of myocardium as far posterior to the obtuse marginal arteries as possible [16, 17, 18]. Pacing sensitivity and thresholds are checked, and if measures are satisfactory, the lead is passed through the anterior port site, tunneled from there to a prepectoral pocket, and connected to the generator [16, 17, 18].

After another check of pacing thresholds, the wounds are closed in layers with absorbable sutures, and a pleural drain is placed through one of the port accesses [16, 17, 18]. This technique represents a valid alternative to standard thoracotomy, is less invasive for the patient, shows good aesthetical results, and requires shortest times of Intensive Care Unit and hospitalization [16, 17, 18].

Robotically Assisted LV Lead Placement

Robotically enhanced manipulation systems can be helpful in managing difficult anatomical conditions, such as in re-do operations; however, the equipment is prohibitively expensive for most institutions [19].

The da Vinci robotic surgical system is the device used for surgical approach [19], figure 4. General anesthesia with selective right lung ventilation is used with patients positioned in the full posterolateral thoracotomy position, and a camera port is placed in the seventh intercostal space along the posterior axillary line [19]. The left and right arms of the robot are positioned in the ninth and fifth intercostals spaces, and a working port is inserted posteriorly to the camera port, for the introduction of leads and sutures [19].

Figure 3. Port and instrument positioning for thoracoscopic approach to left ventricle. Three ports are used as standard access to the left ventricle, and are indicated by red circles. The first is positioned in the mid-axillary line, in the third or fourth intercostal space, for the insertion of the thoracoscope, a second port is placed inferior to this in the fourth or fifth intercostal space, and a third port is placed anteriorly in the fourth or fifth intercostal space. On the right part of figure representation of ports and instruments for thoracoscopy. The use of thoracoscopy can allow a safer procedure than left mini-thoracotomy, warranting better exposure and perfect control of the pacing site and reduced surgical trauma.

Figure 4. In this figure the robotic approach. This system can be helpful in managing difficult anatomical conditions, such as in re-do operations; however, the equipment is prohibitively expensive for most institutions. The da Vinci robotic surgical system is the device used for surgical approach.

Leads can be placed along the posterolateral left ventricle surface using the robotic arms [19]. Pericardial closure is performed, and the leads are tunneled to the left subpectoral pocket and connected to the device [19].

Trans-Apical Epicardial Left Ventricular Pacing via Left Minithoracotomy

This procedure is performed by hybrid and/or by transthoracic echocardiography, used to locate the LV apex [13].

After marking the access site, a left minithoracotomy is performed in the better position to reach the left ventricular apex [13]. After reaching the pericardial surface, a small pericardiotomy is performed above the LV apex and stay sutures are positioned [13]. A standard active fixation endocardial pacing lead (bipolar electrode) can be positioned in the LV cavity through the apex [13]. Hemorrhaging from the LV can be easily prevented with one or two 5/0 or 4/0 monofilament purse-string sutures at the puncture point [13]. The leads are inserted using Seldinger technique utilizing a peel-away sheath, and the apex is punctured with a needle and a guidewire is inserted [13]. The needle is removed from the apex and a dilatation of the apex hole is performed, using the peel-away sheath inserted over the guide [13]. After removal of the guidewire, the pacing electrode is positioned into the LV cavity through the sheath, and peelaway sheath is removed [13]. After effective endocardial fixation of the lead tip, the pacing and sensing parameters are measured [13, 20]. Purse-string sutures in the apex are tied to restrict the movement of the electrode through the apex and they are ligated to the body of the electrode to stabilize position [13, 20]. The pericardium can be partially closed and a pleural drain is inserted, and followed by a standard minithoracotomy closure [13, 20]. The proximal body of the electrode is tunneled to an infra clavicular pocket [13, 20]. Lifelong anticoagulation is mandatory for these patients (similarly to transseptal CRT) [13, 20]. The trans-apical endocardial CRT has potential advantages, such as shorter procedure times, and decreased post operative burden [13, 20].

CONCLUSION

Cardiac surgery approach is efficient to reach the target LV epicardial area [11-20]. The continuous technical and procedural innovations have led this technique to be an important and resolute approach in CRT pacing. In fact, starting from median thoracotomy, the first surgical LV lead positioning approach, the surgical technique has come to video-assisted and robotic approaches, representing important ameliorating in implant technique [11-20]. The surgical techniques result in low radiation exposure time, and high success percentage rate [11-20].

Therefore, surgical approach remains a consolidate and resolute technique in selected and challenging CRT cases. In these cases, percutaneous approach may be not at all successful. In our opinion, it is relevant do not abandon failing heart patients, trying to perform in anyway a CRT. These remain the cases to treat by a surgical approach, to get an epicardial CRT. We think that peri operative complications may limit the clinicians enthusiasm, but this should not scare us in solving the problems in the best way. We have not to abandon this approach, trying to improve the surgical techniques, and lowering the peri operative complications rate, rendering more safe the surgery approach.

ABSTRACT

In oncological surgery, the liver still remain a challenge for surgeons. From the seventies, when liver surgery spread, techniques and strategies to approach parenchymal resection are very changed: from a radical surgery, to the finding of liver regeneration capacity and the concept of minimum remnant size, until now, where new liver regeneration theories and new physiological data are changing our approach. In case of HCC, or in case of metastatic disease, when resection is indicated, there are several diagnostic feature to perform before candidate a patient to surgery. How could be safe a liver resection? Which is the phatophysiological etiology of post-hepatectomy liver failure? How could we expand the safe limits for surgery? All these questions are key-points to better understand liver disease, and, moreover, their treatments. From the first meeting with patient affected by liver cancer, we would like to describe how to manage patients, which kinds of imaging we should prefer, how to assess safe limits for resections, and, in case, how to expand this limit. Then, we will focus on interventional radiologic and surgical strategies to approach liver cancer, and how and why post-hepatectomy liver failure could be prevented and diagnosed correctly. Particularly, we would focus on portal vein embolization, two-staged hepatectomy, and ALPPS, always with physiological explanation, from the most up-to-date clinical evidence. Particular attention will be made for liver surgery's sequel and risks. Comparing the newest data available in literature, we will focus on diagnosing, staging and surgical planning to approach liver resections correctly.

INTRODUCTION

In the latest decades an important change was registered in liver surgery, related to the progress of surgical techniques, anesthesiology and postoperative treatment, allowing a sharp decrease in mortality and morbidity. However, management of liver cirrhosis or small size hepatic remnant still remains a challenge [1].

The liver presents regenerative capacity, allowing performance of repeated resections. In certain cases, when this capacity is impaired, or where extensive resections were performed with small remnant liver, these patients may develop small for size syndrome (SFSS) with the presence of reduced liver mass insufficient to maintain normal liver function. Surgeons continue to push the envelope of what can be defined as “resectable” disease by performing extensive liver resections that challenge both the oncologic and technical definition of respectability [2]. Within this context of extended resection, postoperative liver failure, because of an insufficient functional liver remnant, remains a real concern, especially in patients who have received extensive preoperative chemotherapy. The term SFSS was first employed in liver transplantation to describe the development of acute liver failure (ALF) (hyperbilirubinemia, coagulopathy, encephalopathy and refractory ascites) resulted from the transplantation of a donor liver that was too small for a given recipient [3]. A similar syndrome, called “post-hepatectomy liver failure (PHLF)” was also described in hepatic surgery involving extended resections of liver mass. The last one is characterized by postoperative liver dysfunction, with clinical signs of prolonged cholestasis, coagulopathy with reduced synthetic liver function, ascites and portal hypertension with progressive encephalopathy, renal failure SIRS and death. PHLF is the major cause of death after liver resection often associated with sepsis and ischemia- reperfusion injury (IRI) [4] and remains one of the most serious complications of major liver resection, with an incidence up to 10% of cases [5].

The patho-physiological mechanisms of the SFSS and PHLF are very similar, both presenting reduction of liver mass and portal hyper flow beyond a certain threshold [4]. The pathophysiology of PHLF is described by the following four major factors that influence each others: 1) volumetry (i.e., FRL), 2) quality of liver parenchyma, 3) liver function and 4) liver haemodynamics (i.e., arterial and portal inflow as well as hepatic outflow). Among them FRL remains the major factor influencing the risk of PHLF. Preoperative augmentation of the FRL may represent a possible resolution to the problem. The liver possesses the specific competence to return to a constant size within a short period after injury [7-8]. We can observe this clinically in the form of regeneration after liver resection or liver transplantation, and after toxic liver injury. Liver regeneration involves hyperplasia of all the cell types of the liver. In humans, hepatocyte replication generally starts within a day of major hepatectomy, and replication of non-parenchymal cells, such as endothelial cells, Kupffer cells, and biliary cells begins somewhat later [9]. Liver regeneration is triggered by altered hemodynamic factors. After liver resection, the increased portal vein flow past hepatocytes or sinusoidal endothelial cells initiates regeneration and regulates the size of the liver. Shear stress on the endothelial cells is the powerful impetus for regeneration, liver volume regulation, and growth, as well as atrophy [10]. Hemodynamic factors increase the shear stress in the liver, and nitric oxide (NO) is secreted. NO then initiates the liver regeneration cascade.

R0 resection with zero mortality is the ultimate goal for hepatobiliary surgeons, especially for the treatment of extensive hepatobiliary malignancies. The safety of liver resection is dependent on the function of the future liver remnant (FLR), and an inadequate FLR volume is related to a significant increase in postoperative mortality and morbidity due to the incidence of PHLF. Therefore, various criteria for the FLR volume have been proposed to secure the safety of major hepatectomies according to the extent of underlying injury in the liver [11-12]. However, these criteria for FLR volume often cause clinical dilemmas for surgeons in determining the surgical indications for patients with small FLR volumes because the safety of surgery and oncological radicality are, by nature, conflicting factors. Multiple strategies to increase the size of the future liver remnant (FLR) and thereby decrease the risk postoperative liver failure have been applied.

In the history of hepatobiliary surgery, there have been two outstanding approaches for the safe management of patients with very small FLR volumes. The first was the development of techniques that manipulate the portal blood flow to induce hypertrophy of the FLR.

Makuuchi et al., first described the use of portal vein embolization (PVE) to induce hypertrophy of the FLR before extensive liver resections [13]. Embolization of the right portal vein with inclusion of segment IV was shown to induce up to 70% volume increase within the standardized FLR (sFLR) 6 weeks. Increasing evidence has suggested that hypertrophy of the FLR induced by portal flow modulation is associated with an improved safety of major hepatectomies [14-15]. In addition, dynamic volume parameters, such as the degree of hypertrophy or the kinetic growth rate, are also very informative for estimating the histologic quality and functional reserve of the underlying liver. The second noteworthy approach was the “two stage surgery” for the resection of multiple bilobar hepatic lesions. This sequential procedure was initially proposed by surgeons at the Hôpital Paul Brousse in Paris, France, with the expectation of allowing interim liver regeneration between the two sequential hepatic resections [16]. An oncological advantage of the two-stage approach has been reported in patients with extensive colorectal liver metastases [17], and this procedure used in conjunction with (as first described by Jaek et Al) [18] or without PVE has been adopted by numerous hepatobiliary centers. These two evolutionary approaches have expanded the indications for surgery, and many patients with extensive liver tumors have benefited from surgery using these approaches. However, a remaining issue is that these approaches require at least several weeks to complete the entire clearance of the tumor burden within the liver. Some authors have suggested a risk of tumor progression during the waiting time after PVE [19-20]. Therefore, the time lag between the preoperative intervention and resection can be critical, especially for the treatment of patients with borderline resectable tumors and/or oncologically highly aggressive tumors.

Furthermore, 19–33% of patients who undergo PVE fail to undergo the second-stage operation due to insufficient hypertrophy and/or progression of disease during the time between PVE and the planned resection [21, 22]. More recent publications have described the ALPPS technique (i.e., the associating liver partition with portal vein ligation for staged hepatectomy) as a strategy for accelerated and extensive hypertrophy in the FLR [23-25]. Initial experience suggested that the volume increase after ALPPS is more rapid compared with previous techniques, allowing removal of the diseased hemiliver or extended hemiliver within 6–20 days [26]. The ALPPS technique has demonstrated encouraging results in terms of the degree of liver hypertrophy and the greater proportion of patients who make it to completion of the second stage. ALPPS, however, remains highly controversial, and

substantive concerns have been raised due to the paucity of long-term oncologic results as well as the high morbidity and mortality described in initial reports. Previous reports have described morbidity as great as 40% and inpatient mortality as great as 22% after the ALPPS procedure [27].

The size concept has been demonstrated to be useful in liver surgery management. Otherwise some recent studies conclude that the development of SFSS or PhLF are not strictly determined by the “size” of the liver graft or remnant. It is determined by the hemodynamic parameters of the hepatic circulation and, specifically, by a portal blood flow that, when excessive for the volume of the liver parenchyma leads to over-pressure, sinusoidal endothelial denudation and hemorrhage. Perisinusoidal and periportal hemorrhage occurs in the first minutes after an extended hepatic resection as well as after the reperfusion of a small graft, while arterial vasoconstriction and ischemic cholangitis are observed at later stages [28]. Also, experimental and clinical studies consistently show that an increased portal blood flow relative to the weight of the liver results in an inverse relationship between portal and arterial blood flows that is known as the arterio-portal buffer [29]. The arterio-portal buffer occurs when the portal blood flow increases, the adenosine concentration in the space of mall decreases leading to arterial vasoconstriction and decrease of arterial blood flow, which is responsible for the late damage. Several studies indicate that additionally to blood flow, portal pressure can also be considered a go higher values of hepatocyte growth factor (HGF) and diminished levels of vascular epithelial growth factor (VEGF), suggesting that an increased portal pressure also influences liver regeneration [30]. Studies involving extended hepatic resections also indicate that the increased portal blood flow with diminished residual parenchyma are a critical factor determining the development of PHLF [31, 32]. This lead to the development of a new paradigm: small for flow liver failure (SFFLF) [33]. The aim of this review is to discuss applicable peri-operative methods to prevent the SFSS or PHLF and highlight the main treatment types introducing the new concept of SFFLF.

SECTION 1. POST-HEPATECTOMY LIVER FAILURE (PHLF)

From Transplantation Experience to Oncological Surgery Environment

Liver function impairment is the most feared complication of liver surgery. It consist in a wide pattern of clinical manifestations that can range from mild hepatic dysfunction with isolated hyperbilirubinemia, to irreversible liver failure, which could lead to the death of the patient. This condition can arise in patients undergoing both hepatic resection and liver transplantation. This days, it is still difficult to provide uniform definition of it, because over time each of the many authors who have been confronted with it, provided a definition based on his personal working experience. In 1996 Emond et al., [1] first described this clinical manifestation following transplantation of small graft in living donor liver transplantation (LDLT), introducing the concept of Small For Size Syndrome (SFSS). SFSS is a consequence of size mismatch between graft and recipient, an event occurring especially in the setting of LDLT. When the liver volume is too small to provide to the metabolic demand, the liver loses

his peculiar ability, resulting in delayed synthetic dysfunction, coagulopathy, prolonged cholestasis and intractable ascites. Those factors can lead to septic complication and/or gastrointestinal upper bleeding that results in high mortality rate. Emond showed that early function of the graft significantly decreases if the graft is smaller than 50% of the expected liver volume, concluding that clinical recovery after a small-for-size transplant is characterized by significant functional impairment associated with paradoxical histologic changes typical of ischemia. These changes apparently are due to graft injury, which can only be the result of small graft size. Few years later, in 2005 Dahm et al., [2] proposed a more systematic definition. According to this author, SFSS was the result of graft-dysfunction after partial liver transplantation, and it was defined as the presence of two of the following criteria recorded on three consecutive postoperative days: serum bilirubin $> 100 \mu\text{mol/L}$ (6mg/dL), international normalized ratio (INR) > 2 and presence of encephalopathy grade III or IV. Diagnosis is possible only after the exclusion of other causes leading to similar clinical pattern, such as technical complications (e.g., arterial or portal thrombosis; outflow congestion, bile leak), immunological (e.g., rejection) or infectious (e.g., cholangitis, sepsis). In Dahm's analysis, SFSS usually occurs within 7 day after surgery.

Table 1. Consensus definition and severity grading of PHLF by ISGLS

Grade	
A	abnormal laboratory parameters, but requiring no change in the clinical management of the patient
B	deviation from the regular clinical management but manageable without invasive treatment
C	deviation from the regular clinical management and requiring invasive treatment

Patient related	Male gender Age > 65 years Malnutrition Comorbidity ASA score elevated	!
Liver related	Cirrhosis Steatosis Fibrosis Cholangitis Chemotherapy-associated steatohepatitis	
Surgery related	Small remnant liver volume Blood loss $> 1,250$ ml Prolonged operation time	

Meanwhile in the field of hepatic resection, technical improvements during last two decades have provided extension of indications for major hepatectomies, and so the risk of post-hepatectomy liver failure (PHLF) has gained important concerns. As SFSS in liver transplantation, PHLF is a postoperative clinical manifestation that occurs when the volume

of remnant liver is not sufficient to provide for metabolic demanding. In order to standardize the definition of PHLF for prediction of early mortality after hepatectomy, in 2005 Balzan et al., [3] proposed the “50-50 criteria”. The authors stated that the persistence of either PT < 50% or a serum bilirubin > 50 $\mu\text{mol/L}$ (3mg/dL) on 5 postoperative days proved important for predicting mortality and might be considered as indicator of PHLF. The main result of the study was to demonstrate that the conjunction of these two values on 5 postoperative days, the so called “50-50 criteria”, could predict nearly 100% morbidity rate and 50% mortality rate.

Recently the International Study Group of Liver Surgery (ISGLS) [4], considering the normal postoperative course of serum bilirubin concentration and International Normalized Ratio (INR), has proposed defining PHLF as a “postoperatively acquired deterioration in the ability of the liver (in patients with normal and abnormal liver function) to maintain its synthetic, excretory, and detoxifying functions, characterized by an increased INR (or need of clotting factors to maintain normal INR) and concomitant hyperbilirubinemia (according to the normal limits of the local laboratory) on or after postoperative day 5”. The ISGLS differentiated also the severity of PHLF in 3 grades from A to C. The classification is shown in Table 1. Even if SFSS and PHLF recognize the same pathophysiology, and can be viewed as the same manifestation of liver function impairment, the two terms remains currently separated.

Epidemiology

Selecting the recent series incorporating a modern definition of PHLF, the incidence varies from 0% to 2% after resection on healthy liver parenchyma, but can reach 7% after major hepatectomy [5]. In cirrhotic liver PHLF ranges to 10% after limited resections, and reaches over 30% after major resections [5]. PHLF represents the leading cause of mortality after liver resection (>60%) [6], which varies from 0% to 8% depending on the extension of the resection and the status of underlying liver parenchyma [7, 8] (up to 32% in cirrhotic patients) [9]. Because death may occur beyond the 30th postoperative days, mortality at 3 months should be considered [10].

Risk Factors

In order to better select patients suitable for surgery, several risk factors to PHLF have been identified, (Table 2). The right selection of the patients and the improvement in surgical technique can prevent PHLF. Appropriate postoperative management may decrease the risk of PHLF.

Considering patient-related risk factors, age > 65 years old, male gender, malnutrition, presence of co- morbidities (lung disease, renal insufficiency) and the American Society of Anesthesiology Score (ASA score) are major predictors of PHLF [11]. This patient-related risk factors limit the ability of the liver regeneration and favor postoperative morbidity. Also diabetes is considered a major risk factor, since insulin play a central role in hepatocyte function regulation [12]. Experimental studies showed that even if this hormone is not a mitogen factor of hepatocytes, the lack of insulin results in atrophic liver [13]. Obesity is not an independent risk factor for PHLF, but non-alcoholic fatty liver disease have been proved to

be responsible for increasing rates of non-viral related liver cirrhosis, which is strongly related with PFLF [14]. Others risk factors regarding the remnant liver, for which it is intended both the parenchyma status and the future liver remnant (FLR) volume.

The assessment of FLR is made by imaging-technique, usually requiring CT-scan. Different rates of FLR are allowed, depending on underlying liver parenchyma status [15]. With a normal function, FLR should range between 20% and 30% of total liver volume [16]. In “injured” livers, resulting from steatosis, cholestasis, fibrosis or chemotherapy, the FLR should be greater than 30%-40%. Cirrhotic patients require more than 40% of FLR [16]. Therefore, an accurate preoperative assessment of liver function is needed. Cirrhosis is a major limitation to hepatic resection. The increased risk is explained by a frequent association with other risk factors and by a reduction of both liver functional reserves [17] and regenerative capacities [18].

The Child-Turcotte-Pugh (CTP), is the most used score system for the preoperative assessment of liver functional status. It is evaluated by considering five different variables: serum albumin and bilirubin, INR, presence of ascites and encephalopathy. Three different functional classes are identified: class A (score 5- 6), class B (7-9) and C (10-15). Patients with CTP B or C are considered at high risk for PHLF [19]. Even if it was considered the gold standard for the risk stratification of patients undergoing hepatic surgery, CTP score alone has proved to be inadequate for the correct stratification of PHLF risk in patients with compensated cirrhosis (CTP score A). In those patients PHLF can happen because of low functional liver reserve [20, 21].

Figure 1. Selection criteria for patients undergoing liver resection according. to Makuuchi.

Other methods have been developed for evaluating liver function. The Model for End Stage Liver Disease (MELD) score was initially developed to predict the mortality of cirrhotic patients receiving transjugular intrahepatic porto-systemic shunts, and subsequently used as a disease severity index for priority on the waiting list for liver transplantation. It considers the following parameters: INR, serum bilirubin and creatinine. It was recently shown by several evidence-based studies that a save resection was possible if MELD score < 12 (82% sensitivity and 89% specificity for PHLF incidence) [22]. When MELD score > 12, morbidity rate raises to more than 50%, with PHLF risk rate > 15%, and associated mortality rate > 29% [22, 23]. In Eastern countries measurement of plasmatic clearance of indocyanine green (ICG) is a popular and largely used test to assess the functional liver reserves [24]. ICG is an injectable organic anion that binds to albumin. Its hepatocyte uptake is followed by its biliary excretion without entero-hepatic circulation. ICG clearance is a reflection of liver function, hepatic energy status, cardiac and arterio-portal blood flows. The ICG test evaluates the percentage of retention at 15 min (ICG 15') after administration of 0,5 mg ICG/Kg. Reference ICG 15' value is estimated around 10%. Patients suitable for major liver resection must have ICG 15' < 14-17%; for minor liver resection ICG 15' < 22% is allowed [24]. Portal hypertension (PHT) is a well known risk factor for PHLF, and is often a contraindication to major liver resection [25], especially without preoperative portal vein embolization (PVE) [26, 27]. PHT is usually related to a mild-moderate liver disease with minor functional liver reserve, and associated with poor outcome. According to BCLC staging system for the management of hepatocellular carcinoma [28], the presence of clinical signs of PHT, such as splenomegaly, esophageal varices or hypersplenism (with platelets count < 100000 U/ μ L), is a contraindication to liver resection. The reliable quantification of the portal gradient requires a central venous catheterization and measurement of wedged and free hepatic venous pressure. The presence of hepatic portal vein gradient (HPVG) > 10 mmHg is considered a contraindication to liver resection [19, 28]. However some authors state that PHT should not be considered as an absolute contraindication to liver resection, especially in patients with well compensated liver cirrhosis (CTP A and/or MELD score $\leq$ 10). In those patients postoperative complications related with PHT, such as bleeding from the rupture of esophageal varices or coagulopathy and or low platelets count, can be safely managed with adequate pre, peri and postoperative treatments [29, 30].

In the context of PHT, the decision tree developed by Makuuchi et al. [31] (Figure 1) may be used. It includes presence of ascites, bilirubin level and ICG clearance. A more than four segment resection requires a normal ICG 15' value, a two to three segment resection can be performed if the rate is < 20%, in case of ICG 15' > 30% only limited resection is safely feasible [32]. Also Cholestasis is associated with increased morbidity [33] and PHLF. The interruption in the enterohepatic bile circulation increases the risk of portal bacteremia [34], and it's also associated with a limited hepatocyte regeneration due to reduced secretion of hepatocyte growth factor (HGF) [35] and the braking of hepatocyte proliferation pathways (C-Myc and cyclin E)[36]. In animals, supplementation with bile salts or internal drainage [37] improves liver regeneration, unlike external drainage [38]. Fatty liver, and more widely non-alcoholic steatosis hepatitis, predisposes to PHLF by impaired microcirculation [39], by a greater susceptibility to ischemia-reperfusion lesions and an increased oxidative stress [40]. Preoperative chemotherapy in management of liver metastases of colorectal cancers is a well-defined risk factor for PHLF as well. Two types of chemotherapy-induced lesions are described: (1) the "Sinusoidal Obstruction Syndrome" after oxaliplatin [41] which can lead to

nodular regenerative hyperplasia, and (2) the “Chemo-Associated Steato-Hepatitis” (CASH) after irinotecan [42] which corresponds to a macro-vacuolar steatosis associated with lobular inflammation and hepatocytes ballooning. This toxicity causes significant morbidity, [43] but the accountability of chemotherapy on the PHLF remains debated, particularly for oxaliplatin. Karoui et al. [44] have shown that neoadjuvant chemotherapy was associated with increased postoperative morbidity (38% vs. 14%) and with an increased incidence of PHLF (11% vs. 0%). Soriano et al. [45] have shown that oxaliplatin alters post-PHx proliferation in animal models. This alteration does not affect post-PVE hypertrophy [46]. To date, no increased postoperative mortality in humans has been shown after oxaliplatin, unlike irinotecan which increases the morbidity/mortality and the incidence of PHLF [47]. The impact of targeted therapies has been less evaluated, but it appears that morbidity and mortality are not increased, if stopped 6 to 8 weeks before surgery [48, 49]. Bevacizumab does not appear to alter the volume gain after PVE [50] 52 and perhaps prevents vascular lesions induced by oxaliplatin [51]. In murine experimental models, sorafenib does not impair liver regeneration if stopped before surgery [48].

SECTION 2. CLASSICAL APPROACH: THE CONCEPT OF SIZE

TLV and FLRV: How to Calculate?

In the last decade, in order to achieve microscopically radical resection margins in primary and secondary liver malignancies and thus better survival, surgical treatment has become more aggressive, resulting in an increased rate of complex and extended liver resections [1, 2]. Postoperative outcomes mainly depend on the size and quality of the future remnant liver (FRL). Liver resection, when performed in the absence of sufficient FRL, leads to post-resection liver failure, or “small for size syndrome” with an incidence ranges from 0.7 to 9.1% and a mortality of 80% [1-3].

Therefore an accurate methods to assess function of the FRL in the workup of candidates for major resection, has become an important issue, for hepato-biliary surgery [1, 4-7].

In a young and otherwise healthy patient with normal underlying liver parenchyma, commonly has reported a FLR cut-off values of 20–30% of the patient’s total liver volume (TLV), while in patients with underlying hepatic disease (cirrhosis, cholestasis, steatosis) the critical FLR cut-off value rise up to 30%-40% [2, 3, 8-11].

In order to correctly and precisely determine an optimal FRL, different imaging modalities (i.e., CT, MRI, US) were employed in clinical practice. Mainly the measurements of liver volumes were performed directly on cross-sectional imaging, computing the remnant to TLV ratio using only functional nontumoral liver as representative of TLV. Alternatively, the technique described by Vauthey’s group [12], that consists of estimating TLV, based on a patient’s body surface area (BSA), measuring the future liver volume on cross-sectional imaging, and then calculating the percentage of the FLR that can now be considered to be standardized to the patient’s BSA [2]. In this setting the computed tomography (CT) volumetry (CTV) has been widely used as a method for the preoperative volumetric assessment of the liver. The use of other imaging methods, such as magnetic resonance imaging (MRI) and ultrasound, have also been explored and have shown reliable organ volume measurements when the appropriate scanning protocols are employed [13]. The current gold standard, in the preoperative assessment of FRL volume, is computed tomography (CT) volumetry, as initially described by Heymsfield et al. [14]. With this technique, FRL volume can be calculated by manually tracing the liver contour in each sectional image and summing up the volume of all slices. The three-dimensional reconstruction is then used to calculate the non-tumorous liver volume, tumor volume, and FRL volume [1]. But should be considered that the manual tracing of the liver contour represents a time-consuming process. Moreover, tumor characteristics, such as small tumor size, multiple lesions, and liver characteristics (e.g., small or large liver due to compromised

liver parenchyma) make CT volumetry an error-sensitive imaging technique [1, 15, 16]. Attempts to use other imaging methods, such as ultra- sound and MRI, for liver volumetry have also been made, and several studies in literature have demonstrated that there exists a strong positive correlation in the virtual liver volume measurement using CT or MRI [13, 17, 18].

MRI has the additional advantage of superior soft-tissue contrast, this may theoretically allow for more accurate segmentation of the liver margins, as well as delineation of any focal hepatic tumours. A good knowledge of the appropriate sequences is important for optimal assessment. However, MRI is more expensive and is unsuitable for patients who are claustrophobic. Moreover, the quality of MRI images is easily degraded by motion artefacts, which may preclude in some cases the precise assessment.

Recently Kitajima et al. [19] reported the possibility of performing liver volumetry by means of conventional ultrasound, with good correlation with the volume of the actual specimen; Xu et al., [20] reported the usefulness of the three- dimensional ultrasound (3DUS) volumetric evaluation: the measured volumes all significantly correlated with the true volumes, with significant intraobserver and interobserver reproducibility [4].

Good concordance has been found between 3D ultra- sound and 3D CTV; however, the use of conventional 2D ultrasound has shown to be less precise compared to 3D ultrasound and 3D CTV [13].

Despite the relative widespread availability of 3DUS probes and a considerable refinement of this technique in recent years, ultrasound has not universally proven to be successful for 3D evaluation of the liver, because of well-known limits, both physical and related to a variable reproducibility of the exam, which mainly depends on the skill of the examiner [4, 13, 21-23].

A factor that may affect the accuracy of volumetric assessment is the scan phase. There are significant differences in the total liver volume and graft-liver volume calculations performed in the different contrastographic phases (i.e., unenhanced, arterial or portal venous phase). CTV based on portal venous phase computed analysis is associated with considerable overestimation, whereas volumetry based on the unenhanced CT phase yields the least significant overestimation. However, even though CTV based on the unenhanced CT phase most accurately matches the actual intraoperative findings, in clinical practice the portal venous phase is typically preferred, because it better delineates the vascular anatomy (hepatic veins, main portal trunk and side branch portal vein) and the margins of any tumour than unenhanced CT of the liver.

Manual, Semi-Automated and Automated Methods of CTV

The CTV has traditionally been performed by manual contour tracing of the hepatic contours and summation of the liver area on each axial section, by a radiologist; however, such manual methods depends on operator expertise, requiring considerable time-analysis. Therefore to speed up the process and avoid useless operations, several automated or semi-automated CT-application method have been proposed to perform the volumetric analysis of the liver. Various techniques and algorithms have been described and employed for the automated methods of volumetry, including three-dimensional (3D) active contour segmentation with geodesic active contour segmentation, also coupled with level set algorithms. This technique mainly based on involves the estimation of the mean CT

attenuation value of the liver, permit to select the initial candidate regions of the liver on each section by using the estimated CT cut-off value of the liver. The liver is then separated from other adjacent organs via the analysis of edge information inside the initially estimated liver. A 3D image of the liver is subsequently reproduced for the calculation of liver volume [13, 24-26].

Automatic segmentation sometimes fails in the analysis of CT images due to the low in contrast or to the missing edges (i.e., similar intensity of liver and adjacent organs or machine noise); therefore several semi-automated methods are proposed to include the user in the “processing work” in order to guide the automated segmentation. This approach provides more flexibility and control over the volumetric determination. Semi-automatic segmentation introduced by Wimmer et al. obtained the highest average performance score of 84.6 as stated in the “2007 proceedings of the Medical Image Computing and Computer-Assisted Intervention workshop” focused on segmentation of the liver. Basically, the described algorithm can be divided into three steps. The first step is manual delineation. Manual delineation works on two-dimensional (2D) multiplanar reconstruction views. It captures the cross-section of the liver by user input control points or live wire (Experiments show that typically six to eight contours can achieve good results). The second step is 3D surface reconstruction, which works by using radial basis function based on the manual delineation. The last step is surface evolution, which evolves the reconstructed 3D surface using a level set framework comprising both image and shape information. In general, semi-automatic methods have been show to outperform automatic methods [13, 27-29].

In terms of duration of examination, the average user time for automated volumetry is around 0.57 ± 0.06 min/case, whereas those for semi-automated and manual volumetry are around 27.3 ± 4.6 and 39.4 ± 5.5 min/case, respectively. This implies a highly effective time-saving measure of >30 min/case if one switched from manual to automated means of volumetric assessment [13, 30].

As accurate liver volume estimation relies on precise segmentation of the liver, theoretically it should expect more accurate results when using CT images with smaller section thicknesses. An inverse relationship between the section thickness and the final obtained liver volumes has been described, being liver volumes obtained from analysis of submillimetre thick CT sections larger than volume calculated from thicker images. A maximum error of 5% in the calculated graft volume should be expected if 6 mm thick sections are used [13, 31].

However, the use of thinner sections translates to a greater number of axial sections needed for segmentation, hence more time required for volumetric analysis. This approach represents a more time consuming process when a manual method of contour tracing is utilized. Supposing that a typical adult liver span is 12 cm, the use of 6 mm or 0.625 mm sections requires segmentation of approximately 20 images and 192 images, respectively. The balance between accuracy of volume estimation and time required for image analysis should be carefully weighed.

With regard to the use of volumetry in MRI, the source data are derived from dynamic 3D Gradient echo images, such as volumetric interpolated breath-hold examination and liver acquisition with volume acquisition. Reiner et al. suggested the use of 6 mm and 8 mm section thicknesses for CT and MRI, respectively, for a good balance between accuracy of calculated volume and time efficiency [32].

Volumetric measurements of the liver have been described beyond the use of dedicated professional software, also by using those software packages on a personal computer. Various authors have used more accessible and generic image processing software to measure hepatic volumes, and these have been found to well correlate with conventional CTV as well as with intra-operative graft volume [33, 34]. They represent a useful and reliable diagnostic tools in routinely work-up, offering a small interobserver variability (up to 5%) in the determination of total liver volumes, resection volumes, and tumour volumes especially when compared to those results obtained from CT scanner-linked software [13, 35].

Rationale and Historical Perspectives of Strategies to Push up Liver Resection's Limits

The liver is characterized by a unique and extraordinary capacity for self-renewal; it is the only internal solid organ in the mammal that can fully regenerate after injury or loss. This occurs through organized proliferation of all resident cell types resulting in restored function. The tremendous regenerative potential of the liver has been recognized since ancient times. In classical Greek mythology, Prometheus, after stealing the secret of fire and introducing it to earthlings, was punished by having an eagle of Zeus feast daily on his liver. His punishment was the ultimate torture, as his liver regenerated eternally while the eagle continued his perpetual daily feeding sessions from a constantly replenished source. This myth show how the extraordinary regenerative ability of the liver was known thousands of years ago. Today, the amazing regenerative capacity of the liver is no longer inspiration for mystical tales but is the basis for modern hepatobiliary surgery [16].

Liver surgery with curative intent has been recognized as the gold standard for the management of primary and secondary liver tumours. A careful selection of patients together with advances in both surgical technique and perioperative management has recently improved results of liver surgery. Most series from centers with extensive experience show an overall operative mortality of less than 5% and a mortality rate of about 1% when considering only patients without underlying cirrhosis [17-18]. Nevertheless, major and extended liver resections are still associated with high morbidity and mortality [19-20]. The most severe postoperative complication is liver failure, due to an inadequate amount of hepatic parenchyma after resection. Adults who have more than 75% of the functional liver resected usually are considered at higher risk for postoperative liver failure (30-35% if cirrhosis is present). It has been demonstrated that the increase of the portal flow into a part of the liver can induce hypertrophy of the same part. A significantly higher volume of FLR correlates with improved metabolic liver function and reduced risk of postoperative liver failure. The redirection of portal flow can be obtained by surgical ligation (PVL), percutaneous embolization (PVE) or by surgical ligation associated with in situ liver partition (ALPPS). The human body responds to partial hepatectomy not by regenerating lost segments, but by inducing hyperplasia in the liver remnant. The process of restoration of liver volume in humans is initiated by the replication of various types of intrahepatic cells (such as hepatocytes and stromal cells), followed by an increase in cell size. PVE, PVL and ALPPS are based on experimental observations reported by Rous and Larimore in 1920 [21] (Figure 2). These authors studied the consequences of segmental portal vein ligation in rabbits and found progressive atrophy of segments with occluded portal veins and hypertrophy of segments with portal vein flow. It has also been clinically observed that segments in which tumors were invading or occluding portal veins spontaneously atrophied while the contralateral lobes hypertrophied. Makuuchi et al. first used the selective occlusion strategy in patients in order to extend the limits of liver resection [22].

Portal Vein Embolization (PVE)

Introduction

Preoperative portal vein embolization (PVE) is a procedure that was first described by Kinoshita [23] and used by Makuuchi in the context of the liver resection for Klatskin tumours in order to increase the size of the future liver remnant [22].

Technique

The goal of PVE is to redistribute portal flow toward the segments of liver that will remain after surgery. Embolization of portal branches must be as complete as possible and should result in occlusion of the entire portal tree to prevent the development of intrahepatic portoportal collaterals.

Ultrasound (US) of the liver is performed to determine the best access route into the portal venous system. Under sterile conditions, access into the portal venous system is gained with US or fluoroscopic guidance or both. The ipsilateral approach (access through the portion of the liver to be resected) is recommended as not to injure the FLR. It was found that the contralateral approach may result in iatrogenic lesions of the future liver remnant [24]. Many embolic materials have been used for PVE (gelatin sponge, nonspherical polyvinyl alcohol particles, alcohol, mixture of n-Butyl-cyanoacrylate and iodized oil and spherical microparticles). Small particles used in PVE can embolize capillary liver system eliminating the problematic of the presence of any shunt with healthy liver that can reduce the hypertrophization FLR frequently present in portal vein ligation [25].

Clinical Course after PVE

Postembolization syndrome, including pain, fever, nausea and vomiting, are usually minimal after PVE [26]. Most patients experience a mild fever following PVE, which subsides within 2-3 days. Likewise, changes in liver function (reflected by an increased total bilirubin value and prolonged prothrombin time) are mild and transient, returning to their baseline values 2-3 days after PVE. The serum AST and ALT values are stable in most of patients.

Histological Changes after PVE

Harada et al. have reported histological changes after PVE [27]. In the nonembolized part there are numerous small or binuclear hepatocytes, proliferative hepatocytes, occasionally mitotic figures but apoptotic hepatocytes were rare. In the embolized part, hepatocyte atrophy was observed, the cytoplasm was more eosinophilic than normal apoptotic cells were detected, predominantly in the perivenular area. Based on these findings, Harada concluded that PVE induces hepatocyte apoptosis leading to the atrophy of the embolized part; the cells in the nonembolized part enter a highly active phase of proliferation within two weeks after PVE.

Results

After a month from PVE, the volume of the FLR is evaluated using imaging and later the patient is subjected to major hepatectomy. Resection rate is around 85%. Reasons for non resection are tumor progression, peritoneal metastases or unsuspected metastases discovered

at laparotomy. Absence of hypertrophy is rare (less than 10% in metastatic liver) but can reach 20% in cirrhotic patients [28]. Many studies have demonstrated that hypertrophy is inversely proportional to the FRL ratio before PVE, meaning that the smaller FRL before PVE will have the larger hypertrophy [28]. In a recent systematic review of a TSH series, (vedi lavoro aldrighetti) despite impressive OS and DFS rates and acceptable complication and mortality rates, a consistent proportion of patients (8–31%) did not progress to stage 2. The common reasons for this “dropout” were interval disease progression (88% of the dropout) and inadequate FLR hypertrophy (4% of the dropout).

Portal Vein Ligation (PVL) and Two-Stage Hepatectomy

Introduction

PVE is usually preferred to PVL, because less invasive, but there are some cases in which PVL can be used to induce liver hypertrophy. The main ones are:

- Impossibility to perform PVE due to technical reasons.
- The need to evaluate the patient with an exploratory laparoscopy to exclude the presence of peritoneal carcinomatosis and to assess the resectability of the disease. The surgeon may submit the patient to a ligation of the right branch of the portal vein during this procedure [29]
- Bilobar liver metastases that require a two-staged hepatectomy or synchronous liver metastasis. In this case PVL may be associated with the resection of primitive tumor in the first stage. The higher invasiveness of surgical closure of the portal vein is offset by the need for surgery prior to liver resection.

Technique

Two-stage hepatectomy utilizes the regenerative capacity of the liver, aiming to perform a safe, curative hepatic resection for initially irresectable tumours [30]. This technique has been developed as a surgical strategy for extremely difficult cases of bilobar multinodular metastatic liver disease. It is applied when it is impossible to resect all malignant lesions in a single procedure, the main principle of this approach is sequential resection by a two-staged hepatectomy. Its goal is to achieve a complete metastasectomy in those cases in which a complete resection with a single hepatectomy would have left a remnant postresection liver too small for patient survival. The objective of the first hepatectomy is to render the final future remnant liver free from disease so that the second liver resection becomes feasible and potentially curative. The success of this method relies on liver regeneration between the two interventions, allowing the second hepatectomy to be performed with a lower risk of serious complications, including postoperative liver failure.

Results

Clinical and experimental studies show opposite results on the embolization technique. One prospective study in patients concluded that PVE is superior to PVL in terms of volume gained, lesser time to hypertrophy, lesser hospital stay, and fewer adhesions during major hepatectomy [25, 31] Another retrospective clinical study shown that PVL is as effective as PVE in inducing hypertrophy of the future liver remnant [32].

Associating Liver Partition and Portal Vein Ligation for Staged Hepatectomy (ALPPS)

Introduction

Recently, a new approach to prevent the onset of postoperative hepatic failure in patients with small FLR has been proposed with the acronym ALPPS (Associating Liver Partition and Portal Vein Ligation for Staged Hepatectomy) and represents an evolution of two-staged

hepatectomy. Patients are candidates for a program of two-stage hepatectomy. During the first stage portal vein ligation and parenchymal transection in situ are performed. After a week, the volume of the FLR is evaluated using imaging and later the patient is subjected to the second stage with major hepatectomy. ALPPS was first described in a publication in the *Annals of Surgery* in 2012 by Schnitzbauer [33]; he described the first series of 25 cases: the study reports an increased percentage of FLR of 74% in 9 days, so more rapid and more effective than normally occurs with the techniques of vascular occlusion (mean time with PVE and PVL: 25-35 days with an hypertrophy of 10-50% [25, 34]). The dramatic effect on liver regeneration can be explained thanks to the interruption of possible collateral vessels between the two portions of the parenchyma, which amplifies the effect of the portal overflow to FLR hindering recanalization of embolized portal branches. The parenchyma to be resected works as auxiliary liver until its removal. Knoefel et al.[35] compare the rate of parenchymal hypertrophy in a series of 22 patients undergoing PVE (12 pts), ALPPS (7 pts). He shows that after PVE the mean FLR volume increased was 37% after a mean of 27 days; After ALPPS rapid growth of a mean of 63% of the FLR was observed within 3 days.

This new approach might also involve a preconditioning phenomenon for the FLR, in which the diseased hemiliver acts as a transitory auxiliary liver that assists the growing FLR in metabolic, synthetic, and detoxifying functions during the critical first week after resection [36].

Even the problem of neoplastic progression in the interval between PVE and surgery, remarkable in the non-embolized liver is partially solved with ALPPS approach because the interval before the curative resection is greatly reduced (mean 7-10 days vs 25-35). Another good reason to emphasize the value of this approach is that it avoids the infiltration of FLR by tumor, especially when the tumor is located close to vascular structures [37]. The main problem with this approach is the high rate of morbidity and mortality. Schnitzbauer refers a morbidity of 64% and a mortality rate of 12%, while Knoefel shows that only two of 7 patients had a course free of complications [33, 35].

Technique

The procedure is performed in two steps. The first stage consists of exploratory laparotomy, assessment of resectability with intraoperative ultrasound and positioning the tumor in relation with vessels. If ALPPS is performed for bilobar liver metastases small metastases in left hemiliver can be resected, if is performed for synchronous liver metastases primitive tumors should be resected. The liver is mobilized and hilar structures are exposed; after the right portal vein branch is identified, it is sectioned. Total or nearly total parenchymal dissection is performed. The raw surface of the diseased liver, being partially ischemic after the first step, might be associated with a higher risk of biliary leaks. The second step is usually performed after an interval of 6-12 days. A computed tomography is performed to demonstrate liver hypertrophy and the procedure is completed by relaparotomy. The right artery, right bile duct and the right hepatic vein are ligated; remaining parenchymal bridges of liver tissue with vena cava and diaphragm is divided, if present.

Results

In ALPPS approach, the portal vein ligation associated with in situ splitting is able to induce enormously accelerated hypertrophy. The neovascularization and persistence of

interlobar perfusion are prevented by performing parenchymal dissection. The nearly total parenchymal dissection induced a median hypertrophy of 74%, which is markedly above the range that can be achieved by portal vein ligation or portal vein embolization alone [33, 35-38]. The median time interval to have hypertrophic effect is nine days. De Santibanes [36] observed a rapid growth of the future liver remnant up to 83% in only six days. In contrast, hypertrophy using portal vein ligation or portal vein embolization is generally after four weeks and achieved a much lower degree of hypertrophy (10-50%) [25-34]. An important point to promote accelerated hypertrophy must be attributed to the *in situ* splitting procedure. This technique prevents formation of vascular collaterals between the left and the right hemiliver. This combination of portal vein ligation and *in situ* splitting is able to induce a much stronger stimulus leading to rapid and marked hypertrophy of the left hemiliver or left lateral lobe. The *in situ* splitting causes disruption on intrahepatic portal collaterals leading to a portal flow deprivation to the excluded segments and redistribution of hepatotrophic factors. Since the publication of the article that first described this procedure (Schnitzbauer et al. [35]) great enthusiasm has surrounded this technique because it offers the possibility to treat otherwise inoperable patients. However, it is important to recall that the high rate of morbidity and mortality must confine this procedure only in selected patients and should only be undertaken by experienced hepatobiliary surgeons in a high-volume center.

Actual gold standard indication for ALPPS are colorectal liver metastases in patients younger than 60 years [37]. Pringle's manouvres, primitive liver disease, previously systemic chemo or radio-therapy, cholestasis, primary biliary tumors (Klatskin tumor's) are risk factor for a worse prognosis after operation for a reduced liver regeneration [37]. The main problem with this approach is the high rate of morbidity and mortality. Schnitzbauer refers a morbidity of 64% and a mortality rate of 12% [33] The promising short-term results obtained so far are difficult to interpret oncologically, because of the heterogeneous group of patients with different underlying pathologies, variable chemotherapy use, and technical variations applied. In conclusion ALPPS is a technique that opens revolutionary perspectives in hepatobiliary surgery, however, the high rate of complications and the lack of a long-term follow-up should limit this procedure in selected patients.

Conclusion

PVE and PVL are associated with comparable results in inducing future liver remnant hypertrophy, but PVE is a radiologic procedure performed under local anaesthesia that exposes patients to fewer risks in terms of comorbidities. PVE is preferable to PVL in all cases do not require a two stage hepatectomy to avoid additional surgery. ALPPS assures the possibility to obtain a higher rate of hypertrophy in a shorter time compared to the traditional techniques even if the complication rate of this procedure is higher. ALPPS should not be considered as substitute for PVE or PVL. ALPPS should be considered to expand the pool of resectable patients and should be indicated in patients with a small FLR who have contraindications to be subjected to PVE or PVL or needing a high growth in a short time of FLR due to high risk of neoplastic progression and tumor dissemination.

SECTION 3. NEW APPROACH: THE CONCEPT OF FLOW

A New Concept: Small for Flow Liver Failure (SFFLF)

The size concept has been demonstrated to be useful in liver surgery management [1] [2] [3] [4], pointing the predominant role of liver remnant respect the number of tumours or their diameter. Nevertheless, recently has been noticed that some patients undergoing major liver resection with supposed safe resection limits can develop post-hepatectomy liver failure as well [5]. This evidence leaded physician to perfection the physiological comprehension of post-hepatectomy liver failure, according to histological findings. In fact, it becomes clear that portal flow and pressure are key points in disease development, regardless the future liver remnant size. Liver function is not dependent only from size, but more from the delicate interrelation between parenchyma and liver vascular system. From this point of view, liver regeneration depends on how much we preserve liver functionality, comprehending how many live cells we leave, and how their physiological blood supply is guaranteed.

Even if imaging shows complete restoration of liver volume after few weeks from surgery, there is no evidence of complete restoration of liver's parenchymal microarchitecture when looking at the liver biopsy of the same patients taken soon after extended resection or transplantation [6] [7]. In the field of oncological surgery, liver regeneration is a very complex problem when it's approaching a malignancy. In fact, liver volume regeneration is not always accompanied by a quick and complete restoration of liver function [1]. Often, it has been noticed a distortion in micro and macro architecture of liver cells [8], with hyperproliferation of hepatocytes, and lack of proper interaction with other types of hepatic cells.

Over portal flow and pressure are pointed as the “primum movens” in the pathophysiology of the syndrome. These phenomenon has been studied by Asencio et al. [9], proposing a new approach to post-hepatectomy liver failure, leading to a predominant role of flow and pressure in the etiopathogenesis, and, consequently, a new management approach for liver surgery and related safe limits.

Because of its small size, liver remnant after major hepatectomy is suddenly submitted to a hyperperfusion induced by the whole-maintained portal vein flow. This acute portal hypertension leads to endothelial damage, that explains liver dysfunction [10]. This hypothesis came out from living donor liver transplantation’s experience, where it has been noticed the good outcome of portal flow and pressure modulation strategies to avoid small-for-size syndrome. In fact, in transplantation context, reducing portal vein pressure (PVP) by portocaval shunt [11], or by splenic artery embolization [12], or by splenectomy [13] had been showed to be very effective as prevention treatments. Ogura et al. [14] strongly showed that LDLT using small-grafts was feasible provided that Portal Vein Pressure was maintained below 15mmHg. In an oncological context, some experimental studies have showed how low PVP after surgery is a protective factor against histological damage, leading to a better functional regeneration of liver [15] [16] [17]. Recently, Allard MA and colleagues [18] observed a significantly higher post-hepatectomy PVP in patients who develop post-hepatectomy liver failure (all definitions considered) compared to those who did not. He suggested an intra-operative PVP cut off of 22mmHg, that is associated with 18.4%-21.1% (depending on definitions considered) of likelihood to develop a Small for flow liver failure, and a 90-days mortality of 12,7%. Several other studies indicate that portal pressure higher than 20mmHg show a decrease from 85% to 38% in their 6-months survival [11].

These new evidences lead different authors to change the approach to post-hepatectomy liver failure, and to the pre-operative management. In fact, it seems as it’s not the size the key point to take under control, but the disproportion between the remnant size and its portal flow, reflected by the values of portal blood flow and pressure. A disproportionate increase of portal blood flow and pressure would lead to a sinusoidal injury, to ischemic injury due to a compensatory reduction of blood flow in hepatic artery, and to impairment of liver regeneration [19]. This could also explain why is required a bigger volume remnant in cirrhotic patients, who have an hyperdynamic splanchnic circulation [20].

Shifting the paradigm, from size to flow, means an important change in pre-operative management of patients candidate for elective major hepatectomy, even for early surveillance strategies after surgery.

According to this, a new definition of post-hepatectomy liver failure could be assessed: *Small-for-Flow-Liver-Failure (SFFLF), a postoperative acquired deterioration in the ability of the liver to maintain its synthetic, excretory and detoxifying functions, which is characterized by serum bilirubin concentration above 50 μ mol/L, HVPg > 10mmHg, Doppler evidences of portal overflow, on or after post-operative day five. This condition, if it’s not correctly treated, could lead to liver failure and exitus.*

The diagnosis is based on the evidence of liver failure after an extended hepatectomy. Any other factor that could lead to liver failure such as anesthesia, iatrogenic damages or biliary structures injuries should be excluded. Thus, high bilirubin levels should be associated to a reduced liver synthetic capacity. INR (if plasma transfusion during or after surgery doesn’t occur) is probably the most suitable parameter, but the serum levels of other proteins synthesized by the liver such as albumin or pseudocholinesterase can be useful. Extra-hepatic

cholestasis should be excluded and, according to small-for-flow theory, portal hypertension should be demonstrated by evaluating portal vein dimension and flow velocity by doppler ultrasound. If this condition is seen, then it became important to measure pressure to plan next therapies (read above). Summing up, SFFLF is a post-hepatectomy liver failure not explained by other causes: to assess it, we need to evaluate Bilirubin and INR levels, and perform a Liver UltraSound Doppler Scan to check portal vein condition. When the condition is diagnosed, we should proceed to perform pressure measurement (HVPG) to decide the best treatment to avoid the latest stage of disease.

After surgery, it is very important to perform a strict control of operated patients. In 48-72 hours after hepatectomy, a raise of bilirubin and INR it's very common due to liver injuries caused by surgery [21] [22]. Currently, a raise of bilirubin $> 50 \mu\text{mol/L}$ (3mg/dl) and INR > 1.7 after 5th day post-op is commonly accepted as early markers of liver dysfunction. These criteria are called "50-50 criteria", as we have described before. Despite this, INR is not a very suitable parameter, because of blood and platelet infusion that are often administrated during or immediately after extended hepatectomy.

According to flow-theory, if a raise of bilirubin is recognized after day 5, different strategies can be adopted. Even if there are lack of evidence tested in SFFLF context, portal hyper pressure is usually diagnosed by Doppler US, through biliary system ectasia (according to AISF's guidelines [23], a diameter threshold $> 13\text{mm}$ has a sensibility of 50% and specificity of 95%). Doppler US scan could be used to assess portal overflow, and a threshold of 250ml/min/100g of liver parenchyma has been indicated as risk factor for SFFLF development [24] [25]. When bilirubin raises, a simply Doppler US could develop the suspect of disease, leading to invasive diagnostic strategies (HVPG measurement) and therapeutic choices, as well as avoiding any other iatrogenic causes. After this indication, portal pressure with HVPG could be measured to develop therapies. Indeed, as previously stated a HVPG $> 10\text{mmHg}$ is associated with functional liver regeneration's impairment (in Tab.1 cut-offs are summarized). As different authors suggest, if a raise in bilirubin $> 50\mu\text{mol/L}$ and HVPG $> 10\text{mmHg}$ is recognized, then we should refer the patient to an interventional radiologist to perform a Splenic Artery Embolization (SAE), to reduce flow and pressure in portal system [26] [27]. In case this strategy is not suitable, we could consider a TIPS, even if this last procedure is affected by higher morbidity than SAE. One of the authors of this article has suggested, in parallel with SAE, daily infusion of Terlipressine or Octeotride (50mcg/hour) until bilirubin falls [28], but this strategy is not confirmed by prospective randomized clinical trials. Even if in pre-operative work-up liver functional test are often taken into account, after hepatectomy these are unsuitable to estimate liver failure's risk, because of vascular changing in the remnant, the same changes that are at the base of syndrome's development. Several studies assessed the role of ICGR15 to predict post-hepatectomy liver failure, but its value diminished once liver failure is established, since the changes in hepatic blood flow impacts the test [29].

Pathophysiology

Although all clinical guidelines are focused on liver remnant size to prevent SFFLF, histopathological findings in patients who received a small graft, as well patients undergoing hepatic resections (comprising more than 70% of the parenchyma), point to a predominant

role of over-flow and high pressure through the portal system in the mechanism underlying the development of the syndrome and, consequently, the hepatic damage [30]. A review of literature, and our experience, support the hypothesis that post-hepatectomy liver failure is due to an excessive portal blood flow for the remnant liver parenchyma, causing over-pressure, and sinusoidal endothelial denudation and hemorrhage.

Few minutes after hepatectomy, perisinusoidal and periportal hemorrhage occurs. Later, arterial vasoconstriction, and ischemic cholangitis are observed [31]. According to several experimental and clinical studies, it has been shown that when there is a portal over-flow in liver remnant, it is possible to observe a fall of arterial flow to the liver, in a sort of inverse relationship, called “arterial portal buffer” [32] [33]. This phenomenon is characterized by decreasing concentration of Adenosine in the Space of Mall after a portal-over-flow, that leads to arterial vasoconstriction and decrease of arterial blood flow, which is responsible for the late damage [19]. The portal vein lacks an intrinsic autoregulation system, so when the liver volume is reduced due to major hepatectomy, it reaches the same portal flow first destined to the whole liver parenchyma. This portal over-flow causes the arterio-portal buffer response. After a period of ischemia, the complement cascade is triggered, leading to the activation of Kupffer’s cells, appearance of reactive oxygen species (ROS), and endothelial cell lesion. During reperfusion a release of cytokines, cell adhesion, activation and recruitment of T-cells and polymorphonuclear cell occurs, resulting in microvascular lesion, inflammation and cell death [21].

In addition, the number of Kupffer’s cells after hepatic resections decreased and the liver’s ability to react to infection also decreased, explaining the high risk of infections (above 50%). A relative increase in the production of endotoxins in the remnant liver is beneficial, once it activates the Kupffer’s cells, triggering the liver regeneration; but if this state is prolonged, it may cause Kupffer’s cellular dysfunction, resulting in difficulty of regeneration and even liver necrosis [21].

As already discussed, our knowledge is mainly based on transplant experimental studies [34]. Jiang et al. had established that portal blood flow of 300 ml/min/100g is the threshold above which the incidence of SFFLF increases significantly [35]. In pigs models, Fondevila et al. have indicated that an increased portal blood flow is both an early stimulus for regeneration and a pathogenetic factor of the sinusoidal damage [19], and they have proposed a porto-caval anastomosis to avoid SFFLF development by preventing a portal blood flow over double of its baseline [36]. Other studies have also confirmed the role of portal pressure. Yagi et al. showed that a portal pressure above 20 mmHg was associated with the development of ascites, coagulopathy, and hyperbilirubinemia as well as with an early hypertrophy of the graft, higher values of hepatocyte growth factor (HGF) and diminished levels of vascular epithelial growth factor (VEGF), suggesting that an increased portal pressure also influences liver regeneration [37].

Utility of Portal Pressure and Flow Measurements

The liver is a richly vascularized organ with a high blood flow of approximately 1.5 l/min of which 80% comes from the venous spleno-mesenteric-portal system. This significant amount of blood, once filtered through the liver parenchyma, flows into the hepatic veins that are tributaries of the inferior vena cava and thus the systemic circulation.

The normal pressure in the portal vein is 7-10 mmHg and 2-6 mmHg in the hepatic veins: physiologically between the portal system and the systemic circulation there is a small pressure gradient (≤ 5 mmHg) which allows the smooth flow of blood in the liver. A gradient between 6 and 10 mmHg defines a preclinical condition of portal hypertension (PH). When this gradient increases above 10 mmHg this is considered clinically significant portal hypertension and ≥ 12 mmHg values define a severe and complicated portal hypertension.

The main underlying causes of PH are due to an increased blood flow to the liver, as an increase in vascular resistance in the portal circulation or intrahepatic at the sinusoidal or post-sinusoidal level, for changes in liver microarchitecture from diseases spread directly involving the liver parenchyma as it can occur in cirrhosis. Portal hypertension and its consequences are considered the main factors aggravating liver cirrhosis, and therefore the presence of PH significantly worsens the prognosis [1].

The portal hypertension complications are mainly due to:

- the stagnation of blood in the venous spleno-mesenteric-portal district that contributes to the development of splenomegaly and hypersplenism, congestive gastropathy, spontaneous bacterial peritonitis, ascites;
- the opening of portosystemic collaterals both superficial and deep. In these cases, the blood from the portal system tends to make its way through normally virtual anastomotic ways with the caval vein system, resulting in increased pressure and variable development of dilated veins of varicose type. The most important venous ectasia are gastroesophageal varices from the rupture of which may result in bleeding with hematemesis and melena which are the main causes of death in portal hypertension [2].

In the presence of significant PH cirrhotic patients compared to non-cirrhotic patients, who underwent surgical resection for hepatocellular carcinoma (HCC), have an increased

incidence of intraoperative complications and also an increased risk of liver decompensation after surgery (appearance of ascites, encephalopathy, jaundice) with a consequent increase in mortality rates and therefore in these patients, surgery should be contraindicated [3, 4].

However in cirrhotic patients different levels of portal hypertension may exist that could not absolutely preclude surgery since of the improvement in recent years in surgical techniques, to better pre-operative assessment and progress in the field of anesthesia and medical care [5, 6].

For these reasons it is important to preliminarily diagnose the existence and severity degree of portal hypertension in cirrhotic patients to be subjected to surgical resection in order to assess the risk.

Hepatic Venous Pressure Gradient

A reliable PH diagnosis is obtained by measurement of portal venous pressure and the evaluation of the porto-systemic pressure gradient. However normally the diagnosis of PH is based on indirect criteria in a clinical-laboratory kind, of diagnostic imaging and endoscopic techniques: the presence of ascites and esophageal varices are strongly indicative of portal hypertension.

There are subclinical forms, clinically not significant or not manifest of PH: the occurrence and the severity of PH is possible to confirm through direct measurement, with very invasive techniques such as catheterization of the portal vein percutaneous transhepatic, transvenous, or during laparotomy through cannulation of the mesenteric or umbilical vein [7], or indirectly through evaluation of the portosystemic pressure gradient (*HVPG - Hepatic Venous Pressure gradient*) [8].

HVPG is the difference between the pressure in the portal vein and the intraabdominal vena cava pressure and currently represents the gold-standard in the evaluation of the presence and the level of portal hypertension.

The measurement of HVPG is performed percutaneously in the angiography suite under fluoroscopy through ultrasound-guided puncture and catheterization of the internal jugular, the common femoral or brachial vein under local anesthesia, deep sedation is required for pediatric patients. The angiographic catheter on a guidewire is advanced into the vena cava (superior or inferior depending on the access route), in the right atrium where a hepatic vein is catheterizing (right or medium) 2-4 cm from the opening into the inferior vena cava. At this point an occlusion balloon or Swan-Ganz catheter is positioned and connected to a calibrated transducer to execute a series of three blood pressure measurements with a free catheter into the non-blocked hepatic vein (*Free Hepatic Venous Pressure - FHVP*) which reflects the systemic venous pressure (normally there is a 1 mmHg difference between the inferior vena cava and hepatic veins) and is recorded on a track. In the same position a balloon placed at the end of the catheter is inflated causing a catheter blockage in the hepatic vein and a complete occlusion to the blood outflow that determines an ideal column of continuous blood from the hepatic vein to the portal vein system. The pressure in the blocked area is quickly balanced between the two systems and its measurement indirectly expresses the sinusoidal portal pressure by determining the so-called wedge pressure (*Wedged Hepatic Venous Pressure - WHVP*).

Subtracting FHVP from WHVP you will get the HVPG as a portal hypertension index:

$$\text{HVPG} = \text{WHVP} - \text{FHVP}$$

All measurements are to be repeated in two different hepatic veins, and the average should be calculated out of three measurements for each vein following the international guidelines [9].

The determination the HVPG is a safe and reliable technique to measure the degree of PH, with a low percentage of complications (<1%), but requires a rigorous technique to obtain correct and reproducible values [9, 10, 11]. Although not very employed, more authors recommend HVPG as an important clinical tool in both the classification and in stratification of risk in patients with cirrhosis since to reproducible information that couldn't be obtained in other ways [12, 13, 14]. In the evaluation of the response to drug therapy the variation in HVPG proved to be an excellent predictor of efficacy in the course of chronic liver disease or as a predictor of clinical events such as the appearance of variceal bleeding, HCC development and survival in particularly elevated HVPG values [15, 16, 17, 18].

Hemodynamic correlation studies have confirmed that in compensated cirrhosis the presence of clinically significant portal hypertension (HVPG ≥ 10 mmHg) is the main independent risk factor associated with the development of esophageal varices and first decompensation of cirrhosis [19].

The assessment of PH is controversial in the selection of cirrhotic patients to be underwent to major liver resection for HCC and in particular the systematic measurement of the HVPG [5, 20].

The guidelines report that in patients with HCC the presence of portal hypertension can be considered a negative prognostic factor and significantly influence the different treatment options [21] or even the type of surgery to be practiced [22].

In literature there are several studies that have analyzed the impact of HVPG measurement correlating with the severity of liver disease and the evaluation and risk stratification in cirrhotic patients to be subjected to surgery.

Bruix et al., reported in the multivariate analysis how the HVPG was the only independent preoperative value of the development of irreversible liver failure in the three months following surgery in cirrhotic patients with HVPG > 10 mmHg [3].

Hidaka et al., [23] in a group of 177 patients with HCC have detected how high portal vein pressure values measured directly in the course of surgery correlated with a worse prognosis both on the results (recurrence-free survival rate 52.5 vs 12%, $p < 0.001$) than on the long-term survival (5-year overall survival rate 63.7 vs 31%, $p < 0.001$).

Llovet et al., [24] have shown that 5-year survival after resection for HCC in cirrhotic patients is 74% in case of HVPG < 10 mmHg, 50% in the case of HVPG of 10 but with normal serum total bilirubin, and just 24% in patients with HVPG > 10 mmHg and total bilirubin ≥ 1 mg/dL.

Other authors have found that the increase of HVPG is associated with postoperative liver failure and mortality after liver resection for HCC in cirrhotic patients, and therefore recommend that the preoperative measure of HVPG must be systematically calculated in these patients in order to predict the risk of liver failure even in Child A patients and therefore the surgery should be restricted only to patients without PH [25, 4].

Stremitzer et al., [26] in a retrospective analysis of 132 cirrhotic patients resected for HCC have already recognized how a preoperative value of HVPG > 5 mmHg introduces possible postoperative complications, suggesting that the 10 mmHg was considered too high for the evaluation of these patients. On the contrary, some authors have recently reported how

a HVPG cut-off of 10 mmHg can be excluded from the benefit of a curative surgery in a substantial portion of patients [27].

This data indicates that patients with compensated liver cirrhosis with HCC should be evaluated for surgery not only through conventional parameters of liver function but also undergoing to liver catheterization and measurement of HVPG [3].

The measurement of HVPG ≥ 10 mmHg defines a clinically significant PH as a target to properly address portal hypertensive patients with chronic hepatitis to a drug treatment or cirrhotic patients with HCC to surgery if the HVPG is < 10 mmHg [28]. In Child A patients with cirrhosis the HVPG has been proposed as a criteria to estimate the extent of liver damage and 'tolerance' in hepatic resection for HCC. This is based on the concept that a liver resection will determinate a reduction in the hepatic vascular bed, an increase in vascular resistance and a consequent increase of the HVPG value. It is generally accepted that patients whose HVPG > 10 mm Hg have greater susceptibility to liver failure with jaundice, ascites and encephalopathy after hepatic resection. This risk is maintained even after a long time and can affect a reduced survival rate and increase the risk of complications after liver resection. However, this concept has not yet integrate into the surgical routine and clinical practice and the HVPG is currently not generally used to decide whether a resection should or should not be performed.

Some disadvantages limit the routine use of the HVPG like the relative invasiveness of the technique, the need for trained physicians to obtain reliable and reproducible measurements and finally the costs associated with the procedure [9]. For these reasons new alternative instrumental methods have been proposed to assess and monitor non-invasively the presence of portal hypertension or quantify the degree of associated hepatic fibrosis which well correlated with HVPG. These include the B-mode ultrasound and Doppler and spectral-US, the transient US-elastography or MR-elastography for assessment of liver or splenic stiffness or the latest application shear wave-US: however the level of the operator's skill, the difficult standardization of these methods, the cut-off varying values and the heterogeneity results obtained in different studies do not allow currently to replace the measure of HVPG in the instrumental assessment of the PH [29, 30].

In conclusion, in the cirrhotic patients with resectable liver tumor suitable for surgery, HVPG have a central prognostic relevance can detect an increased risk of postoperative complications if they have subclinical PH (HVPG > 5 mmHg), a greater risk for persistent liver decompensation if they have clinical and significant PH (HVPG > 10 mmHg) or contraindication to surgery if they have severe PH (HVPG ≥ 12 mmHg).

Doppler US

Diagnostic imaging in portal hypertension, such ultrasound techniques as B-mode, spectral Doppler, color Doppler, power Doppler or the contrast-enhanced ultrasonography (CEUS) are instrumental methods which are non-invasive, fast, highly sensitive and specific to studying the hemodynamic state of the liver in various conditions. For these reasons such methods have been proposed and widely adopted in evaluating the severity of PH in patients with chronic liver disease.

Figure 4. Hepatic Venous Pressure Gradient (HVPG) measurement into the hepatic vein with a catheter in the occluded position (black arrow indicates an inflated balloon).

The knowledge of vascular flow patterns in patients with cirrhosis and PH provides valuable information and therefore hepatic Doppler-US has for many years been considered the most important examination for the diagnosis of cirrhosis and portal hypertension, taking into consideration the repeatability and reliability in expert hands.

There are many B-mode ultrasound parameters associated with the presence of portal hypertension.

The observation of ascites and furthermore the detection of portosystemic collateral pathways in a patient with cirrhosis are considered accurate ultrasound signs of portal hypertension, which are highly specific, as for example is the presence of a recanalized paraumbilical vein, dilation of the coronary- left gastric venous collateral, existence of spontaneous splenorenal shunt, peripancreatic, periportal and pericholecystic varicose dilations.

Among the peculiar two-dimensional US parameters of PH are: splenomegaly (spleen longitudinal diameter > 12 cm); portal vein diameter of >14 mm; no diameter variation on breath of the splenic and superior mesenteric vein.

As for the spectral and color-Doppler ultrasonography we can detect many qualitative and quantitative parameters [31]. Among the qualitative parameters color-Doppler images demonstrates within the main portal vein the presence or absence of portal flow and in the spectral analysis the flow direction (hepatopetal, reversal hepatofugal or alternating). The most important parameters detectable with the spectral Doppler examination are those quantitative and semi-quantitative. The study of the main portal vein allows the acquisition of measurements correlated to PH, such as: the increase of the cross sectional area in mm^2 (A); the reduction of the average portal velocity as peak systolic velocities range < 12-16 cm/s

(V); the increase in the congestion index (A/V); the reduction of blood volume (ml/min); the increase in the pulsatility index or peak systolic velocity.

Other parameters but subject to greater variability are: replaced with a monophasic hepatic veins pattern of the typical triphasic waveform; the change in the impedance and resistance index in hepatic, splenic, renal and superior mesenteric arteries.

The limit of Doppler ultrasound techniques lies in poor reproducibility of Doppler data, especially if monitored over time and with different equipment, related to the poor standardization of measurements without clear threshold values and significant intra- and interobserver variability on the accuracy of quantitative assessments that can only improve within of an intensive training programs and through strict application of well-defined guidelines [32].

The contrast-enhanced ultrasonography (CEUS) is a type of ultrasound perfusion imaging technique widely used in the hemodynamic evaluation and characterization of focal liver lesions. Some researchers have also tried to extend the CEUS indication to the evaluation of chronic liver diseases. In fact, some perfusion parameters obtainable with CEUS were correlated with the degree of hepatic fibrosis or PH, such as: hepatic vein arrival time (HVAT), intrahepatic transit time (ITT), peak signal intensity (PSI), time-to-peak (TTP), hepatic artery arrival time (HAAT), hepatic vein arrival time (HVAT).

Intrahepatic transit time (ITT) is the difference of arrival between the arterial and the venous flow (HAAT/HVAT), detectable to the time delay from the arrival of the microbubbles (coming from the contrast medium injected intravenous) at the hepatic artery to the hepatic vein. Now ITT is the only parameter reproducible which able to diagnose and assess the severity of PH and potentially can replace the measurement of HVPg [33].

Splenic Artery Embolization

General Consideration

The non-pharmacological or medical reduction of splenomegaly and hypersplenism consequences in cirrhotic subjects suffering from PH can be obtained effectively with surgical splenectomy, which however, can impair the body's ability to deal with infections or difficult situations in case of further abdominal surgery interventions.

The splenic artery embolization is a minimally invasive endovascular technique that through the catheterization of the splenic artery with a standard angiographic catheter or microcatheter inside proximal (a source downstream of pancreatic vessels) or distal (splenic hilum, branches of lobar or intraparenchymal division) splenic artery: through the catheter it's possible to place a mechanical occlusion system (coils, plugs) or inject liquid or particulate embolic agents (microspheres of varying diameter 300-1000 μ , polyvinyl alcohol particles PVA, gelfoam, glue) with the objective to occlude partially the splenic artery and achieve a volume of infarcted splenic tissue of at least 50%.

Therefore the partial splenic artery embolization is a technique that has been proposed and used in selected cases, alone or in combination with other treatments, to limit in the long term the effects of hypersplenism in cirrhotic patients. The technique allows the reduction in volume of the vital and functioning splenic parenchyma below 30-50% resulting in an effective increase of altered haematological indices such as trombocytopenia and leukopenia, [34, 35], in particular if the volume of infarcted spleen is large [36].

Figure 5. (A)- Celiac axis angiogram demonstrates a tortuous and lengthened splenic artery. (B) Proximal splenic artery embolization (white arrow) prior to the origin of the pancreatic and short gastric arteries (black arrow).

The splenic artery occlusion and reduction of spleen volume in the short term leads to significant changes in pressure values [37] such as the reduction of splenic venous pressure and WHVP (Wedge Hepatic Venous Pressure), which impact favourably on portal hemodynamics in cirrhotic patients by decreasing the clinical and subclinical PH and consequently reducing the risk of its complications, especially bleeding from esophageal varices.

Patients with least extensive splenic infarct will have a mild to moderate complication such as the embolization syndrome with fever, nausea and pain in the left upper quadrant [38]. These symptoms can usually be easily controlled with narcotics and antiemetic drugs. Fever is secondary to the release of pyrogens from infarcted spleen parenchyma and can be treated with steroids. Ascites and left pleural effusion may also appear.

Major complications could especially happen in cases of extensive embolization from 70-100% of the splenic parenchyma and include formation of splenic abscesses, pneumonia, atelectasia and empyema, pulmonary embolism, portal thrombosis, and death [39].

Although not frequently used as primary therapy for patients with portal hypertension, partial splenic artery embolization can be considered as a useful alternative or additional procedure [40].

The Role of Sae in Small-for-Flow Treatment

Splenic artery embolization has been proposed as a strategy to manage SFFLF due to the pathophysiology of this syndrome. Akamatsu et al. [41] have showed the effect of splenic artery embolization in an in vivo human experimental model: when the splenic artery was clamped, the hepatic artery velocity immediately and significantly increased (16% $P < 0,001$), while in the meantime the portal venous flow also decreased significantly (10% $P = 0,03$). Fifteen minutes after clamping, the hepatic artery velocity remained increased at the level of the initial clamping, whereas the portal flow continued to decrease (16% $P < 0,001$ versus the control group). In transplant recipients, Troisi et al. [42] obtained a 33% portal flow decrease and a 74% hepatic arterial flow increase intraoperatively via splenic artery ligation. These results point on a major role of arterio-portal-buffer response as the main cause of liver hemodynamic changes after major hepatectomy. Most of this experience come from transplantation environment, where the risk of small-for-size syndrome, in living-donor, forces physician to avoid any risk for donor-patients. Intraoperative porto-caval shunts, as well splenectomy or splenic artery ligation/embolization spread to avoid liver failure's risk. Not so much data are described in the context of extended hepatectomy, where the risk to leave a small remnant is high, and could justified a similar approach to transplantation. Other authors [43] [44] have described the results in reducing portal flow and pressure by splenectomy. They have reported intraoperative portal flow measurements, demonstrating 43% and 30% portal flow decreases achieved by splenectomy in 8 and 13 living donor liver transplant recipients. In transplantation's experience, splenectomy could achieve the best reduction of portal flow: in Akamatsu's case series [41], maximal reduction of portal flow was 28%, with an increase of hepatic arterial flow of 31%. Thus, in oncological surgery context, splenectomy, a part when is indicated for other pathological reason, doesn't seem justified, because of SAE's safety, compared to surgical approach.

Chapter 413

MINIMALLY INVASIVE CRANIOSYNOSTOSIS SURGERY

Jordan A. Magarik and Christopher M. Bonfield*

Department of Neurosurgery, Vanderbilt University Medical Center, Nashville, TN, US

ABSTRACT

Craniosynostosis is the premature fusion of one or more of the cranial sutures. Commonly, it results in abnormal skull shapes, and may also lead to growth restriction of the underlying brain if left untreated. Therefore, treatment is undertaken primarily for two goals: to restore a more normal head shape for aesthetic reasons and secondarily to mitigate the risk posed by elevated intracranial pressure. Traditionally, the optimal time for surgical intervention is before one year of age as the bones are more malleable, bone re-growth is quicker and more likely to occur, and rapid brain growth benefits from skull remodeling. Extensive open operations, such as cranial vault reconstructions for sagittal, lambdoid, and multisuture synostoses and fronto-orbital advancements in coronal and metopic synostoses, have classically been performed with good results. However, these surgeries can result in substantial blood loss, high rates of blood transfusion, concern for hypothermia, lengthy ICU and hospital stays, significant swelling, and considerable recovery time. Jimenez and Barone first described endoscopic synostosis repair in 1998. Similarly, Lauritzen has promoted the use of springs to enhance skull reshaping. Minimally invasive procedures have resulted in smaller incisions, less blood loss and transfusions, shorter ICU and hospital stays, quicker recovery, and decreased costs. In this chapter, we will present surgical options for minimally invasive craniosynostosis surgery and review the published outcomes of these procedures.

INTRODUCTION

Craniosynostosis is a condition in which one or more of the calvarial sutures fuse prematurely. It occurs in approximately 1/2500 births, with sagittal synostosis comprising the

* Corresponding Author's Email: chris.bonfield@vanderbilt.edu.

majority of nonsyndromic cases. Our understanding of the biomechanics of craniosynostosis can be traced to the work of Virchow in the mid-19th century. Virchow's law states that cranial growth occurs in a perpendicular plane to a fused suture resulting in elongation of the skull in parallel with the fused suture line. In most cases, compensatory skull growth is adequate to accommodate concurrent brain growth and maturation, and the child is simply left with an abnormal head shape and facial features. However, in some cases, the restricted skull may not provide enough space for the growing brain, resulting in clinical manifestations of increased intracranial pressure (ICP), such as visual impairment, headaches, or an impairment of mental development. Options for treatment of craniosynostosis include traditional cranial vault reconstruction (CVR) or more recently developed treatment modalities such as spring-mediated cranioplasty (SMC) or endoscopic-assisted minimally-invasive craniectomy (EAC). The goal of this chapter is to introduce these modalities from a historical context, to discuss the technical details of EAC, and to review the clinical outcomes of EAC and SMC.

HISTORICAL OVERVIEW

Surgical correction of craniosynostosis dates back to the 19th century with the efforts of Lannelongue in 1890, followed by Lane in 1892. These approaches focused on strip craniectomies. While Lannelongue performed bilateral parasagittal strip craniectomies to release the affected suture, Lane preferred to resect the stenosed suture [1]. Strip craniectomies were performed throughout the next century, with mixed results, and it was not until the mid-20th century that the techniques pioneered by Lannelongue were transformed into the modern era cranial vault reconstruction. It was Tessier and Rougerie in the 1960's who began to focus on the cosmetic results of craniofacial repairs. Out of their work arose more expansive approaches, including large bicoronal incisions, and exposures with fronto-orbital advancement techniques that drove the field for decades [2-4]. Tessier's initial paper describes the technique for Crouzon's and Apert's diseases. His technique included dissection of the periobitum and pericranium as well as multiple osteotomies along the frontal bone, orbits, and nasal bone. Of importance was his emphasis on the flexibility of the approach to allow for correction of one or more craniofacial dysmorphisms including hypertelorism, orbitofacial clefts, orbital malposition, and craniosynostosis [2]. Early efforts by Tessier and Rougerie were quite successful; however the risks of surgery were high. Even in its inception, complications, not too dissimilar from modern complications, included large volume blood losses, dural tears, long hospital stays, and lengthy surgical times with its inherent complications of longer periods under general anesthesia.

In the modern era, cranial vault reconstruction (CVR) is the veritable workhorse for craniofacial surgeons. These techniques are based on Jane and colleagues' introduction of the "Pi" procedure in 1978, which not only addressed the primary suture fusion, but also the global cranial deformity and provided immediate correction [5]. Through a large exposure, the Pi procedure provides the flexibility to remodel the frontal, temporal, zygomatic, and nasal bones, along with orbital reconstruction allowing for a wide array of treatment options for both syndromic and non-syndromic causes of craniosynostosis. Yet, it is the nature of that large exposure and reconstruction that results in longer operative times, higher estimated

blood losses (EBL), increased transfusion rates, longer ICU and hospital stays, and increased costs.

The work of Jimenez and Barone in the 1990's on endoscopic-assisted minimally invasive craniectomy (EAC) laid the foundation for more minimally invasive approaches of craniosynostosis repair. Their technique for correction of sagittal synostosis (discussed later in this chapter), involving two small incisions, strip craniectomy, bilateral osteotomies, and post-operative helmeting, helped define a new era in craniofacial surgery. This approach offered good cosmetic results with less blood loss, decreased transfusion rates, and decreased hospital stays. These patients all went on to approximately one year of helmet therapy as part of their treatment [6], which was introduced about a decade prior to Jimenez and Barone's work by Persing. His work demonstrated both the effectiveness and economy of external orthosis [7].

Concomitantly, Lauritzen et al. developed spring-mediated cranioplasty (SMC) an alternative minimally invasive approach that requires two surgeries: one for the application of the springs and another for their removal. In his case report in a 5-year-old child with Apert's syndrome he describes the technique of strip craniectomy with application of springs applying a varying degree of force along the opened suture. The patient returned three months later for spring removal. No external orthoses were required post-operatively. He reported no exorbitism or midface retrusion at follow-up with good facial advancement and improved sleep apnea [8]. The use of spring-mediated cranioplasty continues at many institutions in the US and abroad and has been applied to a wide variety of craniosynostosis conditions. However, of the three available techniques, it is the least utilized. Later in the chapter, we will discuss how this approach compares with both the endoscopic approach and open cranial vault approach.

Technical Overview of Endoscopic-Assisted Minimally-Invasive Craniectomy (EAC)

In order to understand the benefits of a procedure, one must be familiar with the surgical technique. The technique described is how an endoscopic-assisted minimally-invasive craniectomy (EAC) for sagittal synostosis is performed at our institution. It is based on the original techniques first described by Jimenez and Barone [6]. The patient is placed under general anesthesia and positioned in the sphinx position on a beanbag [Figure 1]. The hair in the areas posterior to the coronal suture and anterior to the patient's lambdoid suture is clipped. The coronal and lambdoid sutures are confirmed with ultrasound. Two 4 cm coronal incisions are marked 2 cm posterior to the coronal suture and 2 cm anterior to lambda [Figure 2]. Incisions are opened with a needle tip electrocautery and dissection is carried out in a subgaleal plane to the anterior fontanelle from the anterior incision, and to the lambdoid sutures from the posterior incision. Bilateral parasagittal burr holes are placed 1 cm lateral to midline under the anterior incision and a craniectomy is performed with cuts parallel to the sagittal suture to the coronal suture. In similar fashion, burr holes are placed under the posterior incision and craniectomy performed posteriorly to the lambdoid sutures. Next, bone scissors are used to make para-sagittal cuts extending from the anterior craniectomy, posteriorly about 1.5 cm to allow easier access to the epidural space with the endoscope. A 30 degree rigid endoscope is then used to visualize the dural surface and adjacent bone. Under

direct visualization the dura was dissected off of the bone in the epidural plane with a suction. Any dural-based veins or bleeding points can be coagulated to avoid large volume blood loss. Subsequently, bone shears are used to complete a vertex strip craniectomy. Dural bleeding is addressed with the bipolar cautery or gel foam. The cut bone edges are coagulated completely with a bovie-suction on high power. Next, bilateral wedge osteotomies are made posterior to the coronal sutures and anterior to the lambdoid suture [Figure 3]. Again, a combination of bovie-suction cautery and bone wax is used to coagulate any bony bleeding. The wound is irrigated and closed in layers using Monocryl on the skin surface.

Postoperatively, the patient is sent to post-anesthesia recovery unit and then to the pediatric intensive care unit. A post-operative CBC is performed the next morning. Generally, the patient spends one night in the hospital and is discharged home. Prior to discharge, the patient is measured for helmet fabrication and helmet therapy is initiated as soon as possible.

Figure 1. The patient is placed in the “sphinx” position, with the head in extension.

Figure 2. Two 4cm coronal incisions are marked 2cm posterior to the coronal suture and 2cm anterior to lambda.

Figure 3. Bony removal includes a sagittal strip craniectomy from the anterior fontanelle to lambda and bilateral wedge osteotomies.

Post-Operative Metrics in Craniosynostosis Repair

The major objective measures used to evaluate and compare outcomes for different craniosynostosis treatment modalities focus on cosmesis, peri-operative care, and cost. Many studies have been published over the last twenty years looking at the advantages and disadvantages for each treatment type. More specifically these studies evaluate cosmesis through measures of cranial index pre- and post-operatively, age of treatment, duration of surgery, blood loss, length of hospital stay, and cost.

Throughout the remainder of this chapter we will take a closer look at the minimally invasive approaches to craniosynostosis repair including EAC and SMC as they compare to one another and to the more traditional open reconstructions.

Endoscopic-Assisted Craniectomy (EAC)

The EAC is the most widely utilized method for minimally invasive synostosis repair. Numerous studies evaluating the technique published over the last two decades can be seen in Table 1 [9, 10]. In his original paper, Jimenez et al. described the EAC technique applied in four patients with sagittal synostosis with a mean age of 1.75 months. All patients did well with no complications. The mean operative time was 1.68 hours, mean blood loss was 54.2 mL, and all were discharged within 24 hours of surgery. All patients went on to be fitted with helmet orthoses [6]. In an early follow-up study by Barone et al. a year later, treated twelve patients were treated with EAC ranging from 0.4-7.8 months of age for sagittal, lambdoid, coronal, or metopic synostosis. Estimated blood loss ranged from 5-150 mL and only one patient requiring a blood transfusion. All patients were discharged from the hospital by day 2 [11]. Two years later in 2000, Jimenez et al. published on a much larger cohort of patients including 59 patients with sagittal synostosis who underwent EAC. His results again demonstrated decreased operative times, excellent cosmetic results, low blood loss, short hospital stays, and low complications rates [12].

Table 1. Endoscopically-assisted craniectomy (EAC) studies

Author	Year	Suture	n	Mean age (mo)	Pre-op CI	Post-op CI	Mean Surgery Time (Min)	Mean EBL (mL)	Mean LOS (days)	Cost (\$)	Notes
Jimenez	1998	Sag	4	1.6	.67	.78	100	54	1.3	14300	Initial case series demonstrating safety and efficacy of EAC
Barone	1999	Sag, Cor, Lam, Multi	12	3.6			96	35	1.2	11700	EAC with decreased operative times, EBL, cost, and LOS, compared to open repair
Jimenez	2000	Sag	59	3.7	.64	.77	50	32	1.1		Follow-up case cohort of 59 patients showing safety and efficacy using cranial indices, however, must be performed on younger patients
Cohen	2002	Sag	5					60-150	2-3		Use of bioresorbable plates instead of post-operative helmet therapy is as safe with similar results when used with EAC
Baumgartner	2003	Sag, Met, Cor, Lam	14	2.5	.67 (Sag)	.78 (Sag)	108 (Sag), 55 (Other)	131 (Sag), 72 (Other)	2.9 (Sag), 2.2 (Other)		Technical overview using the microscope instead of endoscope for visualization of craniectomy, with good results
Jimenez	2004	Sag	139	3.6		>.75 in 87%	60	39	1.1		Good cosmetic results using cranial index, anthropometric, and post-operative radiographic analyses after EAC with low morbidity
Murad	2005	Sag, Met, Cor	19				97	74			Patients treated early with EAC have good cosmetic results with similar safety profile and improved peri-operative metrics compared to CVR
Jimenez	2007	Met, Cor	100	3.9			56	34	1.0		EAC can be applied to coronal and metopic synostosis safely and efficaciously

Author	Year	Suture	n	Mean age (mo)	Pre-op CI	Post-op CI	Mean Surgery Time (Min)	Mean EBL (mL)	Mean LOS (days)	Cost (\$)	Notes
Keshavarzi	2009	Met	16	4.9			101	57	2.5		A review of important patient factors when deciding whether to use open versus EAC
Jimenez	2010	Multi	21	3.2			83	42	1.1		EAC is versatile and can be more widely applied to multi-suture craniosynostosis
Meier	2011	Sag, Met, Cor, Lam, Multi	100	3.1			48	25			Anesthesia experience with EAC in young infants demonstrates the technique can be safely performed in small infants with a low incidence of complications and blood transfusions
Ridgway	2011	Sag	56	3.2	.69	.76	45		1.4		Long-term benefits of EAC are durable and continue to show excellent safety profile
Berry-Candelario	2011	Sag, Cor, Lam, Multi	173	2.9	.69 (Sag)	.77 (Sag)	46		1.4		EAC continues to be safe and effective treatments of multiple forms of craniosynostosis
Shah	2011	Sag	47	3.6	.68	.76	88	29	1.2		EAC is equally effective to CVR with similar safety profiles and shorter LOS
Gociman	2012	Sag	46	3.1	.70	.80	75	56	2.2	12400	EAC is associated with shorter operative durations, shorter LOS, lower EBL, and excellent cosmetic results
Rivero-Garvia	2012	Multi	7	2.1				36	2.3		EAC in young infants less than 4 months of age with multi-suture synostosis is safe and effective with good cosmetic results

Table 1. (Continued)

Author	Year	Suture	n	Mean age (mo)	Pre-op CI	Post-op CI	Mean Surgery Time (Min)	Mean EBL (mL)	Mean LOS (days)	Cost (\$)	Notes
Wong	2012	Sag, Met, Cor	76				83	50	2.1		For properly selected patients, EAC offers a valid alternative to the open traditional approaches
Jimenez	2012	Cor	100				54	20	1.0		The benefits of treatment of coronal synostosis with EAC are durable and safe
Jimenez	2012	Sag	256	3.9		>.80 in 87%	57	27	1.1		The benefits of treatment of sagittal synostosis with EAC are durable and safe
Ersahin	2013	Met	19	3.8			43				EAC is safe and effective and infants under 6 months with metopic synostosis
Gociman	2013	Met	16	2.9			79	83	1.6	12400	EAC metopic craniosynostosis showed improved metopic angle measurements with less blood loss, shorter LOS , and less costs
Jimenez	2013	Cor	115	3.1			55	20	1.0		EAC leads to significant correction in vertical dystopia, nasal deviation, sagittal misalignment, and ipsilateral proptosis in patients with coronal synostosis
Chan	2013	Sag	36	4.7			133	75	1.2	24400	EAC is a cost-effective procedure with less operative risk and minimal postoperative morbidity, however, compliance with post-operative helmet therapy present challenges to treatment

Author	Year	Suture	n	Mean age (mo)	Pre-op CI	Post-op CI	Mean Surgery Time (Min)	Mean EBL (mL)	Mean LOS (days)	Cost (\$)	Notes
Tan	2013	Cor	11	2.0							Early EAC results in similar brow symmetry and better overall facial symmetry in midline deviation than fronto-orbital advancement done later in infancy
Vogel	2014	Sag	21	3.1			81	29	1.1	37300	EAC is far more cost-effective with lower utilization of peri-operative resources than CVR
Han	2015	Sag, Met, Cor, Lam, Multi	140	3.4			71	36	1.1		Rates of intraoperative durotomies and surgical and medical complications were comparable between EAC and open techniques
Zubovic	2015	Lam	4	5.1			59	15			EAC under 6 months of age with orthotic therapy obtained comparable cranial base asymmetry outcomes to open reconstruction
Ghenbot	2015	Sag	16	1.8	.69	.77					Both EAC and CVR resulted in similar cranial vault volumes and cranial indices one year post-op when compared to control subjects
Nguyen	2015	Met	13	3.3							EAC and open repairs of metopic craniosynostosis show equivalent improvements in hypertelorism and trigonocephaly at one year post-op

CI = Cranial Index; Cor = Coronal; CVR = Cranial Vault Reconstruction; EAC = Endoscopically-assisted Craniectomy; EBL = Estimated Blood Loss; Lam = Lambdoid; LOS = Length of Stay; Met = Metopic; Multi = Multi-suture; Sag = Sagittal

The general technical aspect described by Jimenez has remained relatively fixed with slight variations adopted in the years since its development through the use of bio-resorbable plates and slightly variations on the wedge osteotomies [13, 14]. At the author's institution, our technique is similar to that initially described by Jimenez. Jimenez has published widely since 1998 and shown that endoscopic repair can be applied successfully and safely to not only sagittal synostosis, but to syndromic, metopic, and coronal synostosis as well [15-22].

Over the 18 years since its publication, numerous studies have looked at both replicating and improving upon these early metrics with tremendous success. Many reports continue to prove the safety and efficacy of EAC with post-operative helmet therapy. These include larger patient cohorts and various types of craniosynostosis [10, 23-28]. Some of these directly compare EAC to more traditional CVR. Chan et al. evaluated 21 patients who underwent open CVR versus 36 who underwent EAC. The mean age was much younger in the endoscopic group (4.7 months versus 10.6 months in the open group, $p = 0.001$), operating room times were significantly shorter (2.2 hours versus 5.7 hours, $p = 0.001$), EBL was lower (74 mL versus 280 mL, $p = 0.001$) and costs were far less as well in the endoscopic group (\$24,404 versus \$42,744, $p = 0.008$). The endoscopic cohort was also associated with significantly shorter hospital stays. These metrics of shorter hospital stay, lower blood loss, shorter operating room times, cheaper costs have also been repeated in several other studies [29-34].

When looking at efficacy from a cosmetic standpoint the endoscopic technique also proved to be as efficacious as open repair [30, 35-37]. A study in 2011 by Shah et al. retrospectively compared the open CVR against the EAC technique. They used the cranial index (CI) as their cosmetic endpoint. Forty-seven patients were treated with EAC versus 42 with open CVR. The mean pre- and post-operative CI at 13 months in the endoscopic group was 68% and 76% respectively, as opposed to 68% and 77% in the open group ($p = 0.35$) [30]. Another study from St. Louis Children's hospital in 2014 looked at 15 open versus 12 EAC repairs and similarly found no difference in outcome CI. The pre- and post-operative CI were 70.4% and 78.4% in the open group versus 68.7% and 76.6% ($p = 0.18$) [29].

Several more studies have reported alternative cosmetic results with the EAC. Nguyen et al. reviewed hypertelorism correction in metopic synostosis correction. Their group found no significant difference in interzygomaticofrontal distance and intercanthal distance between EAC and open CVR cohorts [35]. Tan et al. reviewed supraorbital symmetry in EAC versus open repair in 22 patients with unilateral coronal synostosis. Similarly, they found no significant difference in the two groups with regard to supraorbital symmetry ($p = 0.54$). The EAC group showed improved facial symmetry in midline deviation when compared to the open group (3.6 degrees versus 1.4 degrees, $p = 0.018$), as well as nasal tip deviation (5.6 degrees versus 2.3 degrees, $p = 0.006$) [10]. Another study by MacKinnon et al. examined ophthalmologic outcomes in EAC versus open repair of unilateral coronal synostosis. They reported no difference in V-pattern strabismus or aniso-astigmatism between the two groups at early follow-up, but a trend toward greater severity V-pattern strabismus and statistically significant increase in aniso-astigmatism in children treated with fronto-orbital advancement at late follow-up (14-45 months of age) [38].

While cosmetic and peri-operative metrics are critical, one other important consideration is parental stress when considering surgical options. Kim et al. examined parental stress in children undergoing open versus endoscopic-assisted repair. They utilized the Parenting Stress Index – Short Form to measure parental stress. Parents were grouped into open or

minimally invasive treatment cohorts and controlled for age, sex, ethnicity, and marital status. They demonstrated a statistically significant reduction in peri-operative stress in parents of children undergoing minimally invasive treatment options [39].

In all major studies utilizing the endoscopic approach, patients are generally less than six months of age. One of the major limitations to the endoscopic method is that it must be performed in young infants when the skull and sutures are malleable enough to be molded in post-operative helmet orthoses. The other major limitation of the endoscopic method is socioeconomic. Post-operatively, these patients must be near a center where their external orthoses can be modified over the course of the first post-operative year. The success of this approach is dependent on reliable caretakers who ensure the infant wears the helmet and will be able to follow-up with the craniofacial clinic for helmet modifications. Over the course of the year, these patients may require 1-3 helmets as their cranial vault reshapes and the brain grows. Other complications reported have included small case series of venous air embolisms during EAC cases and a development of leptomeningeal cysts post-operatively [40, 41]. Other reported limitations include the need for reoperation due to the development of pancraniosynostosis and lower rates of cosmetic success [42, 43].

Spring-Mediated Cranioplasty (SMC)

Spring-mediated cranioplasty (SMC) was developed around the same time as the endoscopic approach however its adoption has not been as widespread. A summary of published studies evaluating SMC is seen in Table 2. In an internet based survey by Doumit et al. in 2014 of 102 craniofacial surgeons in four countries, only 10% of the respondents used SMC as their first-line approach for treatment. CVR was the preferred method used 37% of the time and 35% of those surveyed performed EAC when a patient presented at younger than 4 months of age [44]. Since its inception, many studies looking at age of intervention, efficacy (cosmesis), and safety have shown the SMC can be performed at a younger age, with lower blood loss, and shorter hospital stays than CVR [45-56]. One of the largest retrospective studies performed by Lauritzen et al. in 2008 reviewed the group's first 96 cases using SMC on a cohort of patients with sagittal, metopic, bicoronal, and multiple synostoses. Spring dislodgement occurred in 5% of patients; otherwise, there were no major complications. The mean post-operative CI was 74.0 and significantly increased from 67 pre-operatively in the sagittal synostosis cohort. Mean surgical times and blood loss were 97 minutes and 143 mL, respectively [57]. Another large scale retrospective study of 80 patients by Mackenzie et al. compared cranial vault remodeling in 71 patients versus SMC in 9 patients of their cohort. Their early experience had similar findings with comparable cosmetic gains and safety profile when comparing the two techniques [58]. Recently, Arko et al. published their experience at the Children's Hospital of Philadelphia using SMC in twenty-two patients. Their cohort had an average age of 4.2 months and a mean blood loss of 56.3 mL. The mean hospital stay was just over two days at 2.2 days. The cranial index (CI) was corrected to a mean of 73.7, which was a statistically significant improvement over pre-operative CI [45]. Similarly, David et al. in another single-center experience, reported both statistically significant improvements in blood loss, cranial indices, operative times, and length of hospital stay with treatment of sagittal craniosynostosis [46, 47].

Table 2. Spring-mediated cranioplasty (SMC) studies

Author	Year	Suture	n	Mean age (mo)	Pre-op CI	Post-op CI	Surgery Time (Min)	EBL (mL)	LOS (days)	Cost (\$)	Summary
Ririe	2003	Sag	9	3.9			141	48	3.1		SMC shows similar safety profile with shorter operative times, shorter LOS, and lower rates of blood transfusion when compared to CVR in sagittal synostosis
Guimaraes-Ferreira	2003	Sag	10	3.2	.65	.71	100		6.4		SMC is more effective than the modified pi-plasty procedure with less blood transfusion needed and shorter duration of hospital stay.
David	2004	Sag	15	3.9	.64	.78	32	22	2.2		SMC shows improved peri-operative variables when compared to CVR, with a similar rate of cranial index improvement
Lauritzen	2008	Sag, Met, Cor, Multi	96	3.8 (Sag)	.67 (Sag)	.74 (Sag)	97 (Sag)	143	5.0		A review of the first 100 cases of SMC in craniosynostosis demonstrates the safety and effectiveness of the technique
Mackenzie	2008	Sag	9	7.0			66		4.4		SMC is associated with shorter operative times and excellent safety profiles
Windh	2008	Sag	20	3.5	.67	.71	104	170	6.0		SMC had similar morphologic outcomes as patients undergoing pi-plasty treatment for sagittal synostosis
Pyle	2009	Sag	90	4.4							Long-term experience with spring-assisted surgery has facilitated the development of standardized, reproducible techniques allowing spring design modifications to optimize clinical outcome.
David	2010	Sag	75	5.7	.69	.75		25	1.0	21000	SMC is safe and effective in the treatment of scaphocephaly with low morbidity

Author	Year	Suture	n	Mean age (mo)	Pre-op CI	Post-op CI	Surgery Time (Min)	EBL (mL)	LOS (days)	Cost (\$)	Summary
David	2010	Post	3	6.2			45	35			SMC of the patent lambdoid suture is an alternative technique to expand the posterior cranial fossa with low morbidity
Ririe	2011	Sag	100	4.4			31	15	1.6		Anesthesia peri-operative profiles in one hundred cases of SMC for sagittal synostosis reports facility and comfort with the surgical procedure increase with time and number of procedures performed
Taylor	2011	Sag	7	3.7	.65	.79	46	24	1.4		SMC versus minimally invasive strip craniectomy with parietal barrel staving show similar safety profile, however, SMC was associated with lower EBL and shorter length of stay
Toveitjarn	2012	Cor	18	5.0	.94	.82	155	237	6.3		SMC for syndromic bicoronal synostosis can be safely performed with short LOS, short surgical times, and minimal perioperative bleeding
Tuncbilek	2012	Multi	3	7.0							SMC in patients with cloverleaf skull deformity show good decompression with loss of lacunae, cosmetic outcome, and post-operative calvarial bone ossification
van Veelen	2012	Sag	41	5.8	.67	.75		54			SMC is effective in improving CI with less EBL, operative time, and complication rates. The primary disadvantages of SMC are the need for a second surgery for spring removal and inability to control spring tensile force

Table 2. (Continued)

Author	Year	Suture	n	Mean age (mo)	Pre-op CI	Post-op CI	Surgery Time (Min)	EBL (mL)	LOS (days)	Cost (\$)	Summary
Arnaud	2012	Post	19								SMC can be performed safely and effectively without osteotomies for posterior skull distraction
de Jong	2013	Post	15	26.4			164		4.1		SMC has a superior safety profile over open cranial vault surgery for posterior distraction, however, certain drawbacks such as spring dislodgement and spring skin perforations should be recognized
Arko	2015	Sag	22	4.2	.70	.74	94	56	2.2		SMC is effective and safe in correcting CI, and have lower morbidity than CVR

CI = Cranial Index; Cor = Coronal; CVR = Cranial Vault Reconstruction; EBL = Estimated Blood Loss; LOS = Length of Stay; Met = Metopic; Multi = Multi-suture; Post = Posterior distraction; Sag = Sagittal; SMC = Spring-Mediated Cranioplasty

SMC has also been used not only in the treatment of sagittal craniosynostosis, but also posterior skull expansion in patients with turricephaly. Arnaud et al. reported their experience in posterior skull remodeling using SMC. They successfully applied springs to an already opened lambdoid suture in 19 patients. They showed dramatic cosmetic improvement with post-operative three-dimensional CT imaging without major complications. The major limitations included spring displacement, spring exposure, and difficulty in post-operative positioning as these patients cannot be supine during this period [59].

In order to utilize SMC one must understand the amount of spring force needed for proper correction of the respective synostosis. In a study of 90 patients, Pyle et al. described the varying degree of force need for surgical correction. In their study of sagittal synostosis correction, the range of force applied for the anterior spring was 5.5-9.5 Newtons and 5.5-9.5 Newtons for the posterior spring. The mean post-treatment expansion was 6.65 cm. They demonstrated that spring force was dependent on age, type of deformity, and severity of deformity [60].

The major drawbacks of SMC include the need to perform a second operation in order to remove the springs. This is typically performed 3-4 months post-operatively. Additionally, spring-scalp erosion has occurred, and inability to control the force of the spring has resulted in cosmetic problems. With regards to the latter, more modern techniques are using spring specific forces based on age, type and severity of deformity to mitigate these influences. However, these dynamic forces are subject to occasionally unpredictable cranial and suture movement [1, 55, 61]. Also, several centers reported spring dislodgment in a few patients, as well as a delayed tear in the sagittal sinus and small dural tears [48, 62]. Despite these drawbacks, the short operative times, minimal scalp incisions, and low volume blood losses make this approach a favorable one in the correct patient population.

Other Minimally Invasive Techniques

While endoscopic repair as described earlier in the chapter is the predominant minimally invasive technique other forms have been utilized. Massimi et al. in 2007 described a technique where 4-6 incisions are placed on or near sites of osteotomy cuts to allow for craniectomy and greater access to suture lines for skull remodeling. When compared to open bicoronal exposures for cranial vault reconstruction, the authors reported shorter operative lengths, lower blood loss, short hospital stays and comparable cosmetic results [63]. Other techniques, including the minimally-invasive CVR as described by Mutchnick, and Teichgraeber who utilizes a microscope when performing the craniectomies, have shown both safety and efficacy [32, 33, 64].

Other minimally invasive approaches include distraction osteogenesis (DO). In this technique, a craniotomy is performed with limited dural dissection, and internal distraction devices are applied. Distraction starts typically 2-5 days post-operatively with a goal distraction of 1mm/day. The devices are removed 3-5 weeks after complete distraction. The application of this technique has shown excellent improvements in cranial vault volume, fronto-orbital advancement, shorter operative length, and several case series has a similar safety profile when compared to the other minimally invasive techniques. However, this technique requires a second operation for removal of distraction devices [65-67].

CONCLUSION

Since its development in the 19th century, surgical correction for craniosynostosis has evolved into an effective and safe method of treatment of a multitude of craniofacial deformities. As outlined above, several techniques exist for treatment, each with a unique set of risks and benefits. The goal of this chapter was to highlight each techniques' differences, with an emphasis on the EAC and SMC. The decision on which modality to use depends on a given institutions craniofacial expertise and patient selection. While open CVR continues to be effectively utilized at many institutions, in the appropriate patient population, minimally-invasive approaches have been shown to be safer, equally successful, and more cost effective. Future studies will continue to evaluate these techniques in larger patient populations, increased indications, and also further evaluate outcomes, not only based on cranial shape, but also in neurological development.

Chapter 414

RAISING THE BAR ON PTERYGIUM SURGERY

Arun C. Gulani, MD and Parth G. Patel

Gulani Vision Institute, Jacksonville, FL, US

- The 'No Stitch, No Patch, No Red' Approach.

ABSTRACT

Pterygia and pingueculae are intriguing and some of the oldest pathologies that ophthalmologists confront. Presentations vary in various tissue distributions and vascular patterns from small atrophic lesions to large aggressive vision-compromising fibrovascular growths advanced cases.

Raising the bar

What started over a decade ago with celebrities, news anchors, and models seeking services for cosmetic outcomes of their pterygium, pterygium surgery has become a common demand of men and women from all walks of life. It is seen in a fair number of professional golfers, surfers, and avid outdoor enthusiasts. Although prolonged sun exposure is thought to cause pterygium and pinguecula formation, a genetic predilection has also been observed.

While cosmetic symptoms can seem trivial to ophthalmologists, patient concerns are genuine and range from self-consciousness, low self-esteem, and embarrassment to depression as a result of their ocular appearance. This realization has fueled a desire to continuously raise the bar on ocular surface surgery to a cosmetic outcome.

As in LASIK and cataract surgeries in which we aim for spectacle-free vision with a flawless looking eye, during every step in ocular surface surgery we should constantly think of how we want this patient to look immediately postoperatively and years later. Removing the lesion is one goal and beautifying the eye (with minimal visual impact) is the other goal, but both are essential. Considering the consistent outcomes of our pterygial surgery, patients have been actively seeking pinguecula correction.

The part of the pterygium that is visible is only the tip of the iceberg (Gulani Iceberg Concept). By removing only this visible portion, the main pathology with its tentacles is not addressed and remains hidden under the conjunctiva.

We have continuously studied the presentations and outcomes in improving the surgical approach and outcomes over the years to add an additional way to classify the pterygium based on the adhesion of the head locally, vascularity and surrounding tissue involvement.

Thus our surgical steps involve a lamellar approach along with atraumatic pterygium removal as a conjunctival scar with full dissection right up to the roots, including all arising heads followed by subconjunctival mitomycin-C application and Amniotic graft layering on the sclera with glue and reconstructing the fornix in many cases.

Patients are made to walk up to a mirror One day post-op, to appreciate that their eye looks like it has had no surgery.

The cosmetic appeal of the outcome with the no stitch, no patch and no red approach along with absence of visual deficit is raising the bar in patients now seeking this approach for related ocular surface conditions like pinguecula and conjunctivochalasis.

While the average pterygium recurrence rate is commonly considered to hover around the 39 percent mark, the recurrence rate with his technique is less than 0.5 percent (12 yr follow up).

INTRODUCTION

Pterygium is a fibrovascular growth arising from the conjunctiva of the eye that grows over the cornea. It is one of the most common pathologies seen by ophthalmologists. Factors implicated of causing pterygium include ultraviolet light exposure, chronic stimulation, inflammation, climate, and genetics. Surgical excision is the only treatment available and despite the different techniques tried world over, recurrence rates remain high. Bare sclera resection is a relatively straightforward procedure, but a recurrence rate between 24% to 89% is reported. Multiple strategies have been tried to decrease the high rate of pterygium recurrence including conjunctival autograft, amniotic membrane or stem cell transplantation. Various modalities used to inhibit regrowth are thiotepa, radiation, or mitomycin C (MMC).

MMC is an alkylating compound derived from *Streptomyces caespitosus*. It is used primarily as a chemotherapeutic agent because of its cytotoxic effects in inducing apoptosis. Using MMC following resection has been shown to reduce the rate of recurrence, in part because it can suppress neovascularization. However, attention to detail and meticulous maneuvers are important while using MMC because the apoptotic effects of MMC can potentially lead to other complications such as scleral thinning and ischemia.

In this chapter, we describe a 'No stitch (sutureless), No patch, No red (painless and aesthetically pleasing)' technique for pterygium surgery which gives best results both visually and cosmetically.

Raising the Bar

Pterygium surgery with cosmetic outcomes is no longer something that only celebrities, news anchors, and models seek. It has become a common demand of men and women from all walks of life. While cosmetic symptoms can seem trivial to ophthalmologists, patient concerns are genuine and range from self-consciousness, low self-esteem, and embarrassment to depression as a result of their ocular appearance. This realization has fueled a desire to continuously raise the bar on ocular surface surgery to a

cosmetic outcome. As in LASIK and cataract surgeries, there is today, little room for error in pterygium surgery. Beautifying the eye is just as important as removing the lesion and if possible enhancing vision simultaneously.

Anatomy of the Pterygium

The part of the pterygium that is visible is only the tip of the iceberg (Gulani Iceberg Concept). By removing only this visible portion, the main pathology with its tentacles is not addressed and remains hidden under the conjunctiva (Figure 1).

We have classified pterygium into categories based on the adhesion of the head locally, vascularity and draw test for surrounding tissue involvement.

Figure 1. The Gulani “Iceberg” concept, in which the entire mass—not just the visible portion of the pterygium—is removed. Next day postop appearance is clear with no inflammation.

Pterygia in the Gulani Classification (pictures included):

Head/Neck Adhesion: The adhesion may be Peripheral or Central (this can further be classified into diffuse, focal and density based). In cases of peripheral adhesion the pterygium easily peels off the cornea.

Vascularity: Engorged, tortuous vessels and simultaneous conjunctival fold contracture signifies a more aggressive pterygium.

Draw test: On tugging on the cornea some pterygia may be small in size but outright gritty and deep into the cornea resulting in thin cornea when removed. Also removal of these pterygia is more difficult from the corneal surface. Preparation for this before surgery helps plan a smooth outcome (Amniotic graft itself can be used as a lamellar fill).

Recent techniques have used amniotic membrane, the innermost layer of the fetal membrane, for the treatment of pterygium wherein after the removal of proliferative tissue, amniotic membrane is placed on the sclera and adhered to the sclera with glue.

In this surgical approach, we describe a non-traumatic, “No-Stitch” technique using the criteria below and treat the pterygium as if it were a corneal scar. We should plan for every surgery to leave the vision untouched or improved (corneoplastique principles).

The surgical steps involve a lamellar approach along with atraumatic pterygium removal as a conjunctival scar with full dissection right up to the roots, including all arising heads followed by subconjunctival mitomycin-C application and Amniotic graft layering on the sclera with glue and reconstructing the fornix in many cases.

Criteria for surgical plan:

- Determine the Extent of the pterygium.
- Examine the Density of the pterygium.
- Check for Involvement of adjacent structures.
- Draw test
- Head/Neck adhesion
- Vascularity

Technique

In a typical case, anesthesia is induced with topical tetracaine hydrochloride (Tetravisc Forte, Sigma Pharmaceuticals) applied preoperatively with topical antibiotics. Intralesional anesthesia in the form of lidocaine with epinephrine is used 1-2cc. This also delineates the extent of the pterygium in obscure or recurrent cases (Figure 2). Recently a trend has been noticed among patients seeking Pinguicula surgery requesting for LMA anesthesia. Given that most of these patients are young and healthy and also that sometimes the surgery may be extensive, this does allow for a comfortable experience for the patient with a safe recovery.

Depending on the appearance and draw test, decide to approach the pterygium at the contracted medial conjunctival fold and proceed medial to limbal (Gulani Centripetal approach) or from the head towards the medial conjunctival fold (Gulani Centrifugal approach).

At the start of the procedure, the head of the pterygium is delineated from the cornea underneath. This can be done with posterior-to anterior sweep using the Gulani Pterygium cross-action spreader (Storz TM).

In cases of mild adhesions the pterygium can be easily separated from the cornea (mostly peripheral pterygia) or effectively peeled in a single centrifugal/centripetal movement (Figure 3).

After smoothing the cornea with a specially designed blunt blade, remnant tissue (especially in the gritty kind of pterygium) is meticulously removed with toothed forceps medial to limbal directions always. The blade is used again to smoothen the limbus (Figure 4). A weck cell sponge soaked in 1:1000 epinephrine is used during this time tucked away into the nasal crevice where the cut pterygium is pressured into hemostasis (In this way by the time this step is done, we approach a bloodless field again for dissection. Also as added benefit we have created space for tucking the future amniotic graft).

Figure 2. Intralesional lidocaine with epinephrine to delineate the extent of the pterygium.

Figure 3. Centripetal peeling of pterygium from cornea.

Figure 4. Blade being used to smoothen the limbus.

The most important stage is dissecting the pterygium. The whole plane of the pterygium is delineated subconjunctivally as if separating a fan shaped scar with tentacles into the fornices and medial angle. Keep the pull superior and vertical (to avoid damage to the underlying medial rectus. By cutting vertically instead of horizontally, you can avoid unnecessary involvement of orbital fat, bleeding and accidental damage to medial rectus. (In cases of recurrent pterygium, I habitually use a modified muscle hook-Gulani muscle manipulator to ascertain the anatomy by hooking the medial rectus). When the pterygium mass is removed, it resembles a spreading mass of tentacles. It is important to remove the entire mass to avoid recurrence. The pterygium is dissected carefully superiorly, to avoid buttonholing the conjunctiva and invading the orbital septum, and inferiorly, to avoid cutting the underlying muscles, which is rechecked after the pterygium is removed. There is none to very minimal bleeding during surgery (The cautery is to be used sparingly and then only for cosmetic reasons). Make it a point to patiently pick at the episcleral remnants to clear the underlying sclera in an attempt to remove all pterygium tissue from the area of impact.

Weck cell sponge pieces are soaked in mitomycin-C 0.04% and placed under the conjunctiva (rolled over these pieces) in the area of the dissection and left in place for 30 seconds (Figure 5). Avoid application to sclera (infact dry the sclera with a clean wekcel sponge). After removing the sponges to a full count, the area is flushed with copious balanced salt solution.

Figure 5. Weck cell sponge pieces soaked in mitomycin-C 0.04% are placed under the conjunctiva.

Use the cornea as an illuminated *receiving table* to drape the amniotic membrane which is then placed on the raw area and accepted with a Tyre-Tool technique (To avoid touching the membrane with any instrument) so it slips under the surrounding cut edge of the conjunctiva medially, superiorly and inferiorly (Figure 6). This is then milked to adhere to the globe contour using a specially designed forceps that literally squeegees the graft as it lays on the sclera.

Tisseel glue is now applied under the membrane (Sub-Amniotic, controlled delivery) as two separate components and the membrane squeegeed milked again in two quick sweeps to a pearly white and smooth appearance (Figure 7).

Now turn to the medial fornix and glue the conjunctiva and underlying tenons (Cut as a “C” with medial facing convexity) to ensure closure of any potential space in between. Check

the fornices for excessive glue and clear with a forceps sweep. Too much glue may cause irritation and keratitis next day if left behind.

Figure 6. Amniotic membrane being placed on the raw area.

Figure 7. Tisseel glue is applied sub-amniotically under the membrane.

Figure 8. Blade is used in a single, sweep action to cut the excess graft at the limbus.

Figure 9. Recurrent Pterygia looking clear on day 1 (top) and 1 year post op (bottom).

At this time, take the same 64 blade and in a single sweep action cut the excess graft at the limbus (Figure 8). That excess graft is then peeled away as it clears the cornea and also confirms adhesion of the remaining graft (This allows for no bumpy anatomy at the limbus and patients can resume contact lens wear early)

In Recurrent Pterygia:

The surgery is exactly the same no matter how aggressive and recurrent (Figure 9) the pterygium is.

The bleeding is again very minimal if you follow these pearls in recurrent cases:

Select an area which is more amenable to approach and dissect down into this area until you reach the scleral bed (Most usually the previous ophthalmologist must have done a meticulous job of clearing the sclera). Once you reach sclera, dissect from behind forwards and the whole pterygium mass will lift up very much like a thick plate of armor (“*Armor plate Technique*”). Once again bleeding will be minimal (People try to cut and vigorously dissect. That will lead to bleeding and losing the plane of easy dissection).

In cases of simultaneous, nasal and temporal pterygium surgery, we have seen a case of irregular pupil and a case of strabismus that was corrected. Always insist on patient education including need for informed consent about seriousness of surgery despite the results that we can aim for.

Patients are made to walk up to a mirror next day (One day post-op) to appreciate what their eye looks like. (Tables 1-4).

Description: Subjective Grading: The day after the procedure patients walk up to a mirror, examined the operative site and give a verbal subjective exclamation which is documented as the postoperative patient subjective assessment of appearance. The verbal subjective response is graded on a scale of 1-4. This exclamation is based on the flawless,

clear appearance of the operated eye with equal lid openings. Subjective responses recorded the day after the procedure to measure patient discomfort upon eye movements is also recorded and titled patient subjective assessment of symptoms and is graded on a scale of 1 to 3.

Table 1. Grading of the amniotic graft placement post operatively on day one

Gulani Objective grading of the Post Operative Amniotic Graft Area	Examination Findings on the Amniotic Graft Area
	Grade 1 Clear with good placement.
	Grade 2 Good placement but with bubble-wrap appearance.
	Grade 3 Displaced Graft.
	Grade 4 Sub-amniotic blood.

Table 2. Post operative grading of the cornea on the basis of slit lamp examination

Gulani Objective Grading of the Post Operative Cornea	Examination Findings of the Post Operative Cornea
	Grade 1 Clear.
	Grade 2 Mild Keratitis.
	Grade 3 Clouding at Surgical Site.

Gulani Day One Post-Op Patient Subjective Symptom Scale	Level of Discomfort
GRADE 1	No Discomfort
GRADE 2	Some Discomfort
GRADE 3	Uncomfortable

Pterygium surgery has led itself to an increase in the requests for cosmetic pinguecula removal (Figure 10) for patients in whom their appearance may be troubling to the patient or threatens their livelihood itself (models, sales personnel etc.). Here again, since the bar has been raised on outcomes, pinguecula removal follows the same principle as pterygium surgery.

Additionally, these patients may undergo Laser Vision Surgery and or cataract surgery with Premium lens technologies very soon in succession since the cornea is basically cleared (for Laser PRK) with excellent globe contour or for the suction ring during Lasik and even INTACS. The concept of *Look Good, See Good!*

Figure 10. Next day postop of pterygium and pinguecula surgery.

CONCLUSION

We have follow up of over 500 cases of amniotic graft surgery using the above mentioned technique with a recurrence rate of less than 0.5 % with upto 14 years follow up (Figure 11). It is thus safe to conclude that, the pterygium and pinguecula surgery outcomes (the very next day postoperative) have made aesthetic outcomes a reality, with methods described above.

The important thing to remember is that, no eye surgery is complete without addressing the patient's vision. It is our responsibility to also ensure that we are not jeopardizing vision in any form and in fact provide options for vision correction using modalities like Lasik, PRK, Premium cataract surgery, INTACS etc using Corneoplastique™ principles for an early visual rehabilitation of the operated eye (Figure 12). Also, with numerous patients having undergone Lasik and cataract surgery all over the world, we are seeing patients who need surgery for pterygium / pingueculas after these vision correcting surgeries. Here, it is vital not to affect the vision in any way as these patients shall not tolerate a drop in their excellent 20/20 outcomes.

Thus, the importance of this procedure goes beyond successfully treating pterygium and pinguecula patients with a procedure that offers the opportunity for sparkling white eyes one day postoperatively with a less than 0.5 percent recurrence rate. It also offers a vehicle to maintain the integrity of the ocular surface—or further improve the ocular surface—thereby raising the bar on refractive surgery outcomes. For instance, the elegance of this no-stitch amniotic graft technique enables many patients who were initially non-candidates for laser

refractive surgery or premium lens refractive surgery (due to tissue-induced irregular astigmatism, corneal scars, tear film instability or higher order aberrations) to be safely prepared for vision corrective surgery, such as surface ablation and even premium IOL cataract surgery. The removal of corneal scars and pterygium tissue, and the resultant clear and measurable optical system, in essence safely and elegantly converts patients from non-refractive surgery candidates into refractive surgery candidacy.

Figure 11. Follow up over 14 years.

Figure 12. Corneoplastique techniques to remove pterygium scars and achieve 20/20 vision.

We request all eye surgeons to raise the bar on ocular surface surgery outcomes to those of cosmetic surgery given the capabilities of this procedure.

Chapter 415

RELEVANCE OF C REACTIVE PROTEIN LEVELS IN MORBIDLY OBESE PATIENTS AND AFTER BARIATRIC SURGERY

***Jaime Ruiz-Tovar^{1,*}, MD, PhD
and Carolina Llaveró^{2,†}***

ABSTRACT

The measurement of CRP levels is useful because abnormalities generally reflect the presence and intensity of an inflammatory process. However, CRP measurements in clinical use are not specific to any particular disease, nor can they distinguish infection from other causes of acute and chronic inflammation. Elevations of the CRP occur in association with acute and chronic inflammation due to a range of causes, including infectious diseases and noninfectious inflammatory disorders. Small changes in CRP levels may also occur in association with metabolic stresses in the absence of acute or chronic inflammatory states.

Increased CRP levels have been related with the macro- and microvascular disorders, associating with cardiovascular risk, hypertension, diabetes mellitus, and dyslipidemia. Furthermore, increased CRP levels have also been related with central obesity and secondarily with atherosclerosis and other macrovascular disorders. There is a general consensus that obesity is an eminently inflammatory process. This is justified by alterations observed in obese patients, which affect the secretion of certain cytokines such as CRP, ceruloplasmin, leptin, adiponectin, and interleukin-6 (IL-6), among others. In a parallel way, other researchers have also pointed out alterations in the composition of fatty acids in the erythrocyte membrane of overweight adults. These changes lead to a more frequent status of atheromatosis and arteriosclerosis and finally to a higher cardiovascular risk. Therefore, it has been already described that some inflammatory markers (i.e., CRP, IL-6) are predictors of cardiovascular events.

† Carolina Llaveró, RN.

A recent study of our group has demonstrated that CRP levels are increased preoperatively, but in the postoperative course, a significant reduction was observed at the 12- month postoperative determination; at this moment, all the patients presented CRP values under normal range. Therefore, normalization of CRP values could probably be useful to predict weight stabilization.

INTRODUCTION

C Reactive Protein (CRP) is an acute-phase reactant, synthesized by the liver, mainly in response to IL-6, which is produced not only during infection but also in many types of inflammation. The protein consists of five identical, non-covalently associated subunits, each with a molecular weight of approximately 23 kD, which are arranged symmetrically around a central pore [1-3].

CRP and related proteins with this structure are termed pentraxins, which are a family of pattern recognition molecules involved in the innate immune response. CRP can promote the recognition and elimination of pathogens and enhance the clearance of necrotic and apoptotic cells [4-6].

CRP has both proinflammatory and antiinflammatory actions, although the primary effect may be anti-inflammatory. A major function of CRP is its ability to bind phosphocholine, thereby permitting recognition of foreign pathogens and phospholipid constituents of damaged cells. CRP can also activate the complement system and bind to phagocytic cells, suggesting that it can initiate elimination of pathogens and targeted cells by interaction with humoral and cellular effector systems of inflammation [2, 7]. Proinflammatory effects of CRP include the induction in monocytes of inflammatory cytokines and tissue factor and shedding of the IL-6 receptor. As a result, the CRP response to tissue injury may worsen tissue damage in some settings [8, 9].

CLINICAL USE OF CRP DETERMINATIONS

CRP levels are useful because abnormalities generally reflect the presence and intensity of an inflammatory process. However, CRP measurements in clinical use are not specific to any particular disease, nor can distinguish infection from other causes of acute and chronic inflammation. Elevations of the CRP occur in association with acute and chronic inflammation due to a range of causes, including infectious diseases and noninfectious inflammatory disorders. Small changes in CRP levels may also occur, in association with metabolic stresses, in the absence of acute or chronic inflammatory states. In most inflammatory conditions, CRP becomes elevated as part of the acute phase response. Markedly elevated levels of CRP are strongly associated with infection. Levels of CRP may also be elevated in patients with viral infections, although often not to the degree seen in patients with bacterial infection [10].

RELEVANCE OF CRP VALUES IN THE POSTOPERATIVE COURSE

Infections contribute to significant postoperative morbidity, increased mortality, prolonged hospital stay and additional sanitary costs. An early diagnosis of complications after surgery is still a challenge for surgeons, but it is essential for a better outcome of the patient. Furthermore, this is more important when the patient is planned to undergo an early discharge, because a minimally invasive surgery has been performed, as happens in laparoscopic approaches. In these cases, to have a marker that may alert the surgeon to the development of a septic complication that may not have been clinically evident until then, would be essential to decide whether the patient can leave the hospital or should remain hospitalized for further investigations to discard a possible postoperative complication. This is crucial and could change the management for many patients [11, 12].

Among several markers of inflammation and sepsis, CRP has been widely studied to investigate their accuracy for the diagnosis of bacterial infections. CRP is a useful marker for monitoring the postoperative course and diagnose severe preoperative bacterial infections. These studies have been conducted in gastrointestinal surgeries, most of them performed for malignancies, mainly in colorectal cancer surgery [13, 14]. Increased levels of CRP have already been established for signalling an unfavourable outcome. Furthermore, it is considered an indicator of postoperative surgical and nonsurgical complications. Recently, it has been shown that CRP elevation is predictive of infectious postoperative complications including anastomotic leakage. Though CRP levels are usually increased after surgery, it has been shown that in patients developing complications this elevation is significantly higher [11].

Little is known about the postoperative value of CRP after bariatric surgery. A recently published paper of our group demonstrated that CRP levels 24 hours after surgery is a predictive factor for septic complications after laparoscopic sleeve gastrectomy. A cut-off value was established in 100 mg/dl. Those patients overcoming this level have a 10-fold higher risk of developing postoperative septic complications [16].

Actually, many authors defend the monitoring of postoperative values of CRP rather than establishing a single cut-off point for many gastrointestinal surgeries, based on the dynamics of the molecule. It has been described a correlation between persistent CRP elevation as predictive of septic postoperative complications. Serum CRP levels show a peak 48-96 hours after surgery. In patients with an uneventful postoperative course decreased the peak after 2 days, while a prolonged increase in its levels has been described as an indicator of impending complications [11, 15]. Monitoring the CRP levels after a sleeve gastrectomy seems to be of no benefit, thus it is expected that the patient can be discharged 24- 48 hours after surgery, just coinciding with the CRP peak, so that the decrease of CRP levels cannot be determined [16].

CRP AND CARDIOVASCULAR RISK

Minor CRP elevation (concentrations between 3 and 10 mg/L) has been generally regarded as a marker of what has been called low-grade inflammation. The low-grade inflammatory state differs in several important ways from the acute inflammation that occurs

in response to infection or tissue injury. The acute inflammatory state is associated with the classic signs of inflammation (swelling, erythema, warmth, and pain), while low-grade inflammation is not. Acute inflammation generally shows a marked CRP response while low-grade inflammation shows only minor CRP elevation. The inflammatory response to infection and tissue injury supports host defense, clearance of necrotic tissue, adaptation, and repair, while the purpose of low-grade inflammation appears to be restoration of metabolic homeostasis [17].

Inflammation is a known factor in the development of atherosclerosis and subsequent cardiovascular events. Ongoing inflammation increases the vulnerability of an atherosclerotic lesion to erosion or rupture. CRP is the most extensively studied of numerous inflammatory biomarkers potentially linked to underlying atherosclerosis. When considered alone or in combination with traditional cardiovascular risk factors, elevated CRP levels have been associated with a higher risk of future cardiovascular events [18-21].

Minor degrees of inflammation may reflect obesity, cigarette smoking, diabetes mellitus and insulin resistance, hypertension and different degrees of metabolic dysfunction [10]. C-Reactive protein (CRP) has been associated with the macro- and microvascular effects of hypertension, diabetes mellitus, and coronary artery disease [22-24].

There is a general consensus that obesity is an eminently inflammatory process. This is justified by alterations observed in obese patients, which affect the secretion of certain cytokines such as CRP, ceruloplasmin, leptin, adiponectin, and interleukin-6 (IL-6), among others. In a parallel way, other researchers have also pointed out alterations in the composition of fatty acids in the erythrocyte membrane of overweight adults. These changes lead to a more frequent status of atheromatosis and arteriosclerosis and finally to a higher cardiovascular risk. Therefore, it has been already described that some inflammatory markers (i.e., CRP, IL-6) are predictors of cardiovascular events [25, 26].

According to this, a previous study conducted by our group, revealed that the patients of our sample presented elevated preoperative CRP levels, secondary to morbid obesity status and, in some of them, additionally to Metabolic Syndrome (MetS). However, a significant difference in preoperative CRP values could not be observed between the group of patients with and without MetS. An association between preoperative CRP levels and BMI score could not be either established. It may be that some lower level of obesity predisposes patients to elevated CRP levels. Notwithstanding, there is not a linear relationship between BMI and CRP levels [27].

An interesting finding of our study was the universal normalization CRP levels 1 year after surgery, and in posterior analytical determinations, CRP values remained under normal range in all the patients. Referring to weight loss, it was observed that after 1 year, weight did not present important modifications (increase or decrease over 3 kg). Several authors have affirmed that weight loss after bariatric surgery represents a catabolic state, and CRP has been described as a catabolic biomarker [28, 29]. In our patients, after 1 year, when important weight modifications were not observed any more, catabolism probably stopped, and therefore, CRP levels reached the normal range. Regarding these data, normalization of CRP values could probably be useful to predict weight stabilization [27].

CONCLUSION

In the postoperative course of bariatric surgery, CRP is a relevant marker for detecting postoperative complications. An elevation of CRP > 100 mg/l the first postoperative day, should alert the surgeon the possibility of occurrence of postoperative septic complications, even before it becomes clinically apparent. In these situations, the surgeon must be careful with early discharges of the patients.

CRP levels are mildly increased in obese patients, reflecting that obesity is a pro-inflammatory disorder. After bariatric surgery, when the weight stability is achieved, CRP values normalize as a sign of disappearance of the inflammatory status. Thus, this normalization of CRP values could probably be useful to predict weight stabilization.

POLYTETRAFLUOROETHYLENE PATCHES FOR SHOULDER SURGERY

Michael Nagra¹ and Manit Arora²

¹Mayne Medical School, University of Queensland, Queensland, Australia

²St. George Clinical School, University of New South Wales, Sydney, Australia

ABSTRACT

Polytetrafluoroethylene (PTFE) patches is an undissolvable material that has been used widely in surgical fields for vascular surgeries, abdominal surgeries, and some orthopaedic surgeries related to the knee and nasal bone. Due to PTFE high tensile strength and compatible to human tissue, it is also considered a prime augmentation material for a repair of a massive rotator cuff tear. Studies have shown PTFE patches provide better outcomes in returning to baseline function and tensile strength than in a non-augmented (tendon to bone) repair. It has low infection and adhesion rates, excellent properties to allow for shoulder healing during the “off-load” (rest) period. The use of PTFE augmentation for massive rotator cuff tears is recommended.

INTRODUCTION

Shoulder surgery has progressed rapidly in the last two decades. With these advances, innovations and inventions have become part and parcel of care. One such intervention is the use of Polytetrafluoroethylene (PTFE) patches for the treatment of rotator cuff (muscles and tendons around the shoulder) problems. With small tears we usually can bring the tendon to attach the bone directly, but with larger tears it becomes increasingly difficult. PTFE helps by acting as a scaffold or bridge between the torn tendon and the bone.

The rationale is to “off-load” the torn tendons by mechanical augmentation from the time of injury to some period post surgery. The “off-load” allows the injured tendons to rest while the scaffold material carries the weight and functions of the injured tendons. The “off loading” period produces faster and better healing outcome. It does so by stabilizing the tissue until healing is occurred. This method has also been shown to reduce pain after the shoulder

is healed, as well as producing a higher satisfaction and function compare to non-augmented repairs [1-3].

The ideal synthetic scaffold material should have low to none infection and adhesion rates, as well as being able to provide a good mechanical strength. The material should be able to maintain its mechanical properties over time to help stabilize and to prevent recurrence of the tear. The material used can either be dissolvable in human body, or undissolvable. A concern in an undissolvable material is it may increase risk of infection, which often leads to another surgery to remove the material. Multiple surgeries can subsequently lead to a loss of shoulder strength and function in a long term.

PTFE is an undissolvable synthetic material that can be used as a scaffold patch for massive rotator cuff tears. PTFE has a strong tensile strength and compatible to human tissues, which makes it excellent for biological healing [4]. It is able to provide mechanical support permanently. Its use is similar to abdominal hernia repair that it provides strength and support to abdominal muscles.

The usefulness of PTFE patch is well known, especially in abdominal and vascular surgeries. In hernia operations, PTFE is used to replace musculo-fascial tissue to approximate the abdominal wall [4]. Its benefit in abdominal wall surgery includes low rate of infection [5], low adhesion rate [6], support fibrous tissue incorporation [7]. PTFE patch has been experimented for use as a prosthetic placement of an esophageal wall fragment in rats [8]. In vascular surgery, PTFE patch is used for coarctation repair [9], popliteal bypass [10], vascular graft [11, 12], etc.

In orthopedics, PTFE patch has shown a potential value in restoring knee joints in people with osteochondral defect (defects in knee bone and cartilage) as it allows for growth of tissue through the patch [13]. PTFE patch also shows excellent outcomes when used for Anterior Cruciate Ligament reconstruction in chronic unstable knee with an 83% satisfactory rate [14]. In plastic surgery, PTFE patch has been used successfully to treat small defect of the nasal bone and cartilage [15].

SURGICAL METHOD

The method of using patch augmentation for massive rotator cuff tears is performed via arthroscopic technique. The cuff tears are identified while patient is lying on the lateral side on the uninjured shoulder. Two portals are inserted to the injured shoulder; a lateral viewing portal is used as a cannula for PTFE patch insertion and posterior portal as surgical scope. The PTFE patch is placed as a scaffold into subacromial space (a space in a shoulder) through the lateral surgical portal cannula. The PTFE patch is then secured to the torn tissue via mattress sutures at the anterior and posterior portions of the rotator cuff. The patch is sized via a ruled probe or similar instrument prior to insertion. A pre-operative MRI is helpful for sizing of the patch. The optimal thickness for PTFE patch was estimated between 3-5 mm. There is minor difference in post-operative satisfaction between using small (less than 2 cm anterior to posterior dimension) or large patch size. Patients who received smaller patch size, compare to larger patch size group, have higher abduction strength post-operatively. Thus, the use of PTFE patch thickness 3-5mm and small patch size is recommended. A post-operative rehabilitation is essential for best outcomes.

RESULT

A systematic review for using PTFE patch as a treatment of massive rotator cuff tears found a total of eleven studies (four animals and seven clinical) [16]. A study on 31 beagle dog showed that when a PTFE augmentation is performed on host tissues, it increases tensile strength; but it also causes stiffness of the shoulder after the surgery [17]. Another study showed that weave suture technique, in comparison to multiple mattress suture technique, has a higher success in securing the PTFE patch in animal hosts [18]; and inverted mattress repair provides a higher footprint contact pressure than vertical mattress suture [19]. On sheep experiments, researchers found that interposition surgical repair using PTFE provided a significantly stronger massive rotator cuff tears than direct tendon to bone repair [20].

PTFE patches for massive rotator cuff tears have showed good outcomes in human trials, with as much as 90% patient's satisfactions in return of function post-operatively [21]. A study on 30 patients with irreparable massive rotator cuff tears over 5 years period showed significant improvement on pain score and lack of new development of bone destruction or inflammation [22]. However 30% of patients developed an enlargement of the bone gutter of the greater tuberosity after the surgery, this is believed to be attributed by the patients' biological reaction to PTFE [22]. It hasn't been shown that the use of PTFE is directly related to bone loss, so this phenomenon needed to be studied in the long term. The use of PTFE augmentation repair still needed to be compared with other repair or augmentation technique.

CONCLUSION

PTFE patches for treatment of rotator cuff tear has been found to be effective as it has a high post-operative satisfaction in returning to shoulder function, improved pain score, and lack of bone destruction. It has a high tensile strength and low complications rate related to adhesion and infection. Complications related to enlargement of bone gutter, bone loss, and comparison to other patch materials still needed to be studied in a long term. The use of PTFE patch for massive rotator cuff tears is recommended.

Chapter 417

ANAESTHESIA FOR MINIMALLY INVASIVE MITRAL VALVE SURGERY

Ben Gibbison*, MD and Amit Ranjan

Department of Cardiac Anaesthesia, Bristol Heart Institute/University of Bristol,
Bristol, UK

ABSTRACT

Minimally invasive mitral surgery is a part of the spectrum of minimal access cardiac surgery and fast tracking, which essentially aim to increase patient satisfaction by accelerated recovery and decrease pain, while maintaining overall surgical efficacy. The altered surgical approaches require changes to the anaesthetic technique and equipment. The restricted view of the heart also increases the reliance on trans-oesophageal echocardiography (TOE). This chapter discusses anaesthesia for minimally invasive mitral valve surgery (MIMVS) as well as TOE guided assessment of the mitral valve and placement of cardiopulmonary bypass equipment.

Keywords: anaesthesia, mitral, minimally invasive

INTRODUCTION

First video-assisted mitral valve (MV) repair through a mini-thoracotomy was performed by Carpentier in 1996. Since then minimally invasive mitral valve surgery (MIMVS) has come a long way and with better understanding of mitral valve patho-physiology and state of art surgical kits to operate, it is becoming an established practice for elective isolated MV surgery.

The main drive behind MIMVS is to reduce tissue damage. This leads to a smaller inflammatory response and a faster recovery. Primarily, this is aimed at improving the patient experience – meaning that patients have less pain, feel better and can return to their normal

* Corresponding Author's Email: ben.gibbison@bristol.ac.uk.

life sooner. However, this also aligns with incentives for healthcare providers to reduce hospital stays and improve efficiency. Whilst much of the literature in MIMVS is concentrated on operative techniques, within the process for minimally invasive surgery should be a move towards improving recovery as measured by reduced intensive care and hospital stays [1]. This must be implemented as a “package” of care alongside the minimally invasive approach to surgery. This is a multi-disciplinary effort encompassing pre-, peri- and post-operative interventions.

FAST-TRACKING MINIMALLY INVASIVE MITRAL VALVE SURGERY

The less tissue destruction, change to respiratory mechanics and ultimately inflammatory activation, the fewer the post-operative problems. This is evidenced by trans-femoral TAVIs (trans-catheter aortic valve implants) and Mitraclips® where, without the inflammatory response of cardio-pulmonary bypass (CPB) and sternotomy, are routinely discharged on the second or third post-operative day. Traditionally, high dose opiates are given to cardiac surgical patients to abolish the neuro-hormonal responses to surgical insult. The trade-off of this approach is that patients often needed to be ventilated overnight in an intensive care unit. During the 1990s, fast track cardiac surgery became a way to deal with increasing demand for limited resources. The drive to faster extubation means that in some cardiac surgical units, patients are now extubated “on table” at the end of the case and post-operative care provided in a dedicated post-anaesthetic care unit outside the main intensive care unit [2].

A fast-track approach has been shown to be equally safe and effective compared to ‘standard’ care in terms of morbidity and mortality, but with shorter extubation times and intensive care unit stays [3]. These shorter ICU stays have not yet led to a shorter hospital stay [4] showing that extubation *per se* is not the rate limiting step of intensive care discharge. Indeed patients who fail the fast-track stream may have longer stays than if they were in a ‘standard’ stream [4].

There is currently no level I evidence as yet pertaining to fast-track MIMVS. However, when designing a fast-track protocol for this specific intervention, the same empiric principles apply. Standard definitions of what constitutes fast-track cardiac surgery [3] vary in the literature and between centres, but it is the authors’ opinion that the drive should be towards improving patient care and experience and that efficiencies to the healthcare system are a by-product of providing this high-quality care. A fast-track system should address the whole peri-operative pathway, from patient selection and pre-admission to hospital discharge and follow-up. This is a multi-disciplinary activity comprising the *co-ordinated* efforts of both clinical and administrative staff.

Enhanced Recovery

The stage beyond fast-track cardiac surgery is enhanced recovery (ER). Enhanced recovery is a programme of high quality surgical care that returns patients back to normal function sooner. Enhanced recovery and minimally invasive surgery are inter-dependent: The

benefits of enhanced recovery cannot be realised without less tissue damage and a smaller and shorter inflammatory response. Similarly, the benefits of minimally invasive surgery will not be realised without a systems based approach that moves patients through that system faster. Enhanced recovery works on the principle of “the aggregation of marginal gain” [5]. This means making every part of the peri-operative care pathway as good as it possibly can be for as many patients as possible. The higher the rate of compliance with the elements of the ER, the lower the rate of later than expected discharges. It should be remembered that many of these benefits, whilst small to the individual, amount to large improvements across a population.

There are four elements to an enhanced recovery programme:

1. Pre-operative assessment, planning and preparation before admission:

It is important to involve the patient, their family and their carers in the operation, as well as the patient's general practitioner. This means that the dates for admission, operation AND expected discharge are in everyone's diary. Planning and maintaining a date for operation and discharge makes sure that staff identify and co-ordinate all essential resources. Discharge planning is particularly important prior to admission; having a discharge-ready patient in hospital for more days than is required is a waste of resources and an impact on the patient's life. Pre-operative assessment should be made as soon as the decision to operate has been made. This allows all relevant investigations and consultations to be complete by the time of surgery.

2. Reducing the physical stress of the operation:

This part comprises minimally invasive surgery, maintaining adequate temperature and optimal fluid management.

3. A structured approach to immediate post-operative and peri-operative management, including pain relief:

Structured and protocol driven post-operative care is essential, not only as it ensures that patients are getting the right care, but will identify patients who are failing the pathway. This allows early intervention to manage these problems and return the patients to the fast-track.

4. Early mobilisation:

This is dependent on high quality analgesia and structured physiotherapy. Patients should be ambulated at the *earliest* opportunity.

Key factors that help implement an enhanced recovery programme are:

- Staff training

The multi-disciplinary team must be trained so that they understand the evidence about speeding up recovery after surgery and thus develop a mind-set that allows patients to be active in their recovery. Operating theatre staff need to be formally trained in minimally invasive techniques to ensure smooth process of the operation and keeping operating and cross-clamp times to a minimum.

- Improved processes

The workflow should be planned and scheduled. This means everybody knows what to expect and when to expect it.

- Procedure specific care plans

A generic ‘cardiac surgery’ care plan is no longer appropriate. MIMVS care plans should be separate from aortic valve and coronary artery surgery. The pre-, peri- and post-operative goals are different and therefore should be treated differently. This not only allows early identification of those who are failing, but also allows advanced planning (eg pre-discharge echo, optimal anti-coagulation) to ensure timely discharges.

Once a MIMVS programme is in place, continuous audit of outcomes, including intensive care and hospital stays should be undertaken.

Patient Selection

Patient selection is critical to success in moving patients rapidly through the peri-operative care pathway. In theory, all elective patients should be considered as eligible for a fast-track programme – high risk patients may benefit from optimal preparation, reduced stays in the ICU, and increased mobilisation, although re-admission to the ICU is associated with a poor outcome. Predictors of failure in fast-track surgery are shown below and these criteria should be applied rigorously i.e., if a patient meets any of these criteria at any stage, they should be removed from the fast-track pathway:

- Severely impaired left ventricular (LV) function (<30%) [6]
- Long operative time (>4hrs 30min) [7]
- Long CPB time (>2hrs) [7]
- Impaired renal function (GFR < 65) [8]
- Non-elective surgery [6]
- Pre-operative intra-aortic balloon pump [6]
- ‘Redo’ surgery

It should be noted that when considering impaired renal function, it is the Glomerular filtration rate (GFR) that is the important value, not just the creatinine. Wide variance in GFR can be seen between individuals for the same serum creatinine level due to differences in sex, race, muscle bulk and other inherited and acquired differences [8].

Essentially suitability of MIMVS rest on surgeons, nevertheless, anaesthetists should be aware of pertinent issues. Following group of patients is considered not suitable for MIMVS:

1. Combined Aortic valve surgery with MV surgery
2. Coronary re-vascularisation with MV surgery
3. Ascending Aorta surgery in past
4. Severe peripheral vascular disease
5. Previous surgery in right thoracic cavity, a relative contraindication.

PRE-OPERATIVE ASSESSMENT FOR MIMVS

Pre-operative assessment for MIMV surgery should be the same as any other cardiac surgical operation. That is that the severity and symptoms of the lesion should be established, as well as its consequences of the rest of the heart. The presence and severity of all co-morbidities must also be known. When assessing patients for MIMVS several pre-existing health conditions warrant further investigation:

- Cerebrovascular and peripheral vascular disease.

Peripheral vascular disease is associated with an increased risk of stroke or systemic embolization with retrograde arterial perfusion. A CT of the chest and abdomen will delineate the anatomy of the vascular tree and a contrast angiogram will show potentially hazardous plaques within the lumen. Knowledge of the size and tortuosity of the ilio-femoral vessels helps in correct cannula size selection.

- Previous cardiac surgery, lung conditions and chest wall deformity/irradiation.

Chest wall deformity, irradiation and pre-existing cardiac surgery are all associated with adhesions and previous coronary surgery may mean that grafts cross the operative field. These can all be characterised by means of a CT chest. Airway assessment and pulmonary function tests to assess suitability for one lung ventilation should be assessed in those undergoing surgery via a thoracotomy approach.

- Co-existent coronary artery disease.

If possible, evaluation of this should be carried out before CT angiography of the arterial tree due to the risk of iatrogenic dissection of the iliac artery during cardiac catheterisation. This could be catastrophic if unrecognised when the iliac vessels are cannulated at the time of MIMVS.

- Trans-oesophageal echocardiography (TOE)

TOE is essential for safe conduct of minimally invasive surgery. Therefore, contraindication to TOE should also be assessed. These include oesophageal carcinoma, stricture, varices or prior oesophagectomy. This is discussed in more detail below.

Preoperative Preparation

Numerous methods have been attempted to help patients adequately prepare for cardiac surgery and ensure patients are in optimal condition prior to surgery. However, few of them have any real evidence-base to recommend them. Pre-operative physiotherapy [9] and respiratory exercises [10] have been shown to improve rates of post-operative pulmonary complications (atelectasis and pneumonia) after elective cardiac surgery. Pre-operative carbohydrate drinks close to surgery also have shown benefits in terms of reduced stays, but the Cochrane meta-analysis cautioned against the high risk of bias in these studies [11], although the risk of harm is low.

Perioperative Anaesthetic Considerations

MIMVS requires general anaesthesia. The choice of anaesthetic agent is individual and institute dependent. Sedative pre-medications should be avoided where possible and the anaesthetic agents should have as few 'hang over' effects as possible. The principles of the anaesthetic technique for MIMVS are similar to conventional MV surgery. There are, however, some differences:

1. Positioning: The patient is usually placed in a supine position with the right chest elevated (Figure 1). The right arm is moved slightly away from body to allow improved surgical access. External defibrillator pads are applied because the internal 'paddles' are too large to fit through the smaller access sites. It should be noted that if the defibrillator pads are applied through the deflated lung there won't be effective electric conduction. They should therefore be applied in the antero-posterior orientation on the left chest wall.

Figure 1. Positioning of the patient for MIMVS (with permission of Dr. Solinas).

2. Airway: One lung ventilation (OLV) is not essential for MIMVS. However, a non-ventilated right lung allows surgeons better operating conditions. Lung isolation techniques are individual and institute dependent and each technique has its own advantages and disadvantages. It is the opinion of the authors that a left sided double lumen tracheal tube facilitates isolation and independent drainage of both lungs. Lung protective ventilation strategies using limited tidal volumes and positive end-expiratory pressure should be used where possible. Care should be taken to avoid hypoxia and / or hypercarbia as this may increase the pulmonary vascular resistance as well as the raised pulmonary pressures present in mitral regurgitation (MR). This can precipitate right heart failure which can be diagnosed with the TOE.
3. Cannulation for CPB: Both arterial and venous cannulation for CPB can be achieved peripherally – usually via the femoral vessels. However, axillary as well as ascending aortic arterial cannulation and jugular venous cannulation can be employed. Adequate venous drainage can be obtained with the tip of the venous cannula lying in the superior vena cava and the multi-orificed side ports in right atrium (See TOE section for details). Suction-assisted venous drainage may be needed. Troubleshooting cannulation and the maintenance of CPB is discussed in Chapter XX.
4. Aortic cross clamping: This is achieved either in a conventional manner by a long external clamp (introduced via either the operative or separate incision) or via an endo-aortic balloon clamp (inserted via the femoral or subclavian artery). The endo-aortic balloon clamp is inflated in the proximal ascending aorta under TOE guidance (best seen in the mid-esophageal ascending aorta LAX view). Anterograde cardioplegia can then either be delivered via the distal port of the balloon clamp or via a separate aortic root cannula.
5. Weaning from CPB is no different than conventional MV repair. However, as CPB times for MIMVS are slightly longer than conventional MV surgery, this should be considered in the decision making about post-CPB cardiovascular support.

TOE FOR MINIMALLY INVASIVE MITRAL VALVE SURGERY

Peri-operative TOE is recommended by for all MV repair surgery [12, 13]. TOE is particularly important in MIMVS as the smaller the access sites for cardiac surgery, the more the surgeon becomes reliant on the TOE. Use of the TOE for MIMVS falls into two stages:

- Pre-operative
 - Severity of MR
 - Function of the mitral valve leaflets, apparatus and assessment of pathological segments
 - Risk factors for surgical repair
 - Correct placement of CPB cannulae and apparatus
- Post-operative
 - Ensure sufficient de-airing of the LV
 - Identify residual MR / stenosis and mechanism

- Identify potential complications of MV repair
 - Circumflex artery ligation / distortion
 - Systolic anterior motion (SAM)
 - Aortic dissection

Pre-Operative TOE

Severity of Mitral Regurgitation

Assessment of the severity of MR under general anaesthesia is problematic as the loading conditions of the heart are different to that of the awake, upright person. With this caveat, there are essentially three ways to judge the severity of MR and the overall weight of the evidence used to classify the severity of the MR. These methods are:

- Estimation of Effective Regurgitant Orifice Area (EROA) using proximal iso-velocity surface area (PISA). This is done at a Nyquist limit of 40cm/s (NL40). See Box 1.
- Measurement of the Vena Contracta

The vena contracta is the narrowest point (and therefore the highest velocity) of a colour flow doppler jet measured on the atrial side of the leaflet tips. Less than 3mm is classified as mild and over 7mm is classified as severe. It should be measured with the Nyquist limit between 50 – 60cm/s. This is very useful for single-orifice regurgitant jets, but less useful for multiple orifice jets.

- Assessment of pulmonary vein flow

A normal pulmonary vein flow (Figure 2) has a systolic and a diastolic wave in the same direction from the baseline, with the systolic wave larger than the diastolic wave. As the severity of the MR increases, the systolic wave gets smaller and in severe regurgitation can be retrograde (i.e., in the opposite direction to that of the diastolic wave). In the presence of eccentric jets of MR, both left and right sided pulmonary veins should be interrogated.

Box 1. Severity categories of mitral regurgitation [13]

Mitral Regurgitation	Mild	Moderate	Severe
EROA	<0.20cm ²	0.21 – 0.39cm ²	≥0.40cm ²
Vena Contracta	<0.30cm	0.31 – 0.69cm	≥0.70cm
PISA Radius (NL40cm/s)	<0.40cm	0.41 – 1.00cm	>1.0cm

Figure 2. Pulsed wave Doppler flow of the left upper pulmonary vein flow. Left – normal. Right – the systolic flow reversal seen in severe MR. Note the S and D waves are timed from the ECG.

Function of the Mitral Valve Leaflets, Apparatus and Assessment of Pathological Segments

The LV and the MV are inter-related and therefore assessment of one incorporates assessment of the other. Assessment of LV dimensions and function are required, along with assessment of the papillary muscles, chordae and leaflets. Trans-gastric short axis views at both the mid papillary and basal levels are supplemented with segmental analysis in the mid-oesophageal views. Live, real-time 3-Dimensional (3D) TOE helps in both diagnosis and communication of the lesion to the surgeon and may be superior in detecting some pathologies [14, 15], particularly those around the commissures.

Risk Factors for Surgical Repair

The two complications particular to MV surgery that peri-operative TOE can influence are those of SAM and distortion/damage to the circumflex artery. SAM occurs in around 10% of cases of MV surgery and can vary in severity from mild protrusion of chordae to left ventricular outflow tract obstruction (LVOTO). Several pre-operative factors have been suggested as markers of risk for post-repair SAM [16]. These are:

- Posterior leaflet height > 15mm
- Anterior-posterior leaflet height ratio <1.4
 - These heights should be measured in the mid-esophageal AV 5C view
- Coaptation point to septal distance (C-sept) <25mm

Distortion or damage to the circumflex artery occurs in around 1% of MV surgery and is more likely to happen in those with a left dominant circulation due to the proximity of the circumflex artery to the MV annulus. The circumflex artery can usually be visualised with colour flow doppler as it branches from the left main stem and followed as it runs posteriorly around the lateral side of the mitral valve annulus [17]. To document post-operative change, a pre-operative image is required.

Correct Placement of Cardiopulmonary Bypass (CPB) Cannulas and Apparatus

The correct placement of the arterial and venous CPB cannulae is of paramount importance to avoid complications. The guidewire for femoral placed arterial cannulae is best seen in both long and short axis views of the descending aorta. The wire must be seen in the lumen of the aorta before placement of the cannula itself. The guidewire for the femorally inserted venous cannula should be seen in the right atrium (RA) and is best seen in the bicaval view. The optimal position for a femorally inserted 2-stage venous cannula is with 2-3cm of cannula in the superior vena cava (SVC – See Figure 3). If an SVC cannula is inserted from the right internal jugular vein, then then the femorally placed single stage venous cannula should be entirely within the inferior vena cava. To ensure endovascular positioning of the venous cannulae, some units inject agitated saline that can be seen in the RA. For port-access MV surgery, an endo-aortic balloon is used instead of an aortic clamp. This must be in the ascending aorta and is best seen in the mid-esophageal AV LAX view.

Box 2. Severity of mitral stenosis graded by mean trans-mitral pressure pressure gradient [18]

Mitral Stenosis	Mild	Moderate	Severe
Mean Pressure Drop	<5mmHg	6 – 10mmHg	>10mmHg
Pressure Half Time	<139ms	140 – 219ms	≥220ms

Figure 3. ME Bicaval view of Femoral CPB cannula inserted with tip correctly positioned just inside the superior vena cava. RA – Right atrium. LA – Left atrium. IVC – Inferior vena cava. SVC – superior vena cava.

Post-Operative TOE

Pre-Weaning from CPB

After removal of the aortic cross-clamp (of deflation of the endo-aortic balloon) the circumflex artery should be examined to establish that there is no distortion or damage to the vessel. The heart should be checked for residual intra-cavity air before removal of the surgical vents.

Post-Weaning from CPB

After weaning from CPB the adequacy of the repair should be assessed, along with heart function.

Mitral regurgitation – residual MR should be assessed in the same way as pre-bypass and only after complete weaning. Attempts should be made to assess the adequacy of MV repair under as a close to physiological conditions as possible. This usually requires small boluses of vasoconstrictor.

Mitral stenosis – mitral stenosis after MV repair occurs in around 2% of surgeries. The pressure drop across the repaired mitral valve is Mitral stenosis is graded as in Box 2. Planimetry of the repaired MV can be done in the trans-gastric basal SAX view, or using real-time 3D TOE imaging.

Dynamic left ventricular outflow tract obstruction (LVOT) due to SAM is best seen in the mid-esophageal 5C LAX view and mid-esophageal LAX views. The characteristic findings of MR and a pressure gradient measured in the LVOT are seen. There is a characteristic “dagger” shaped velocity profile in the LVOT seen on continuous wave doppler due the peak gradient occurring in late systole. Other complications that occur after MV surgery that should be sought out by TOE examination are aortic dissection and tethering of the non-coronary cusp of the aortic valve leading to aortic regurgitation.

PAIN MANAGEMENT AFTER MIMVS

One of the advantages of MIMVS is *overall* less pain in the post-operative period. However, the first 24 – 36 hours after thoracotomy may be associated with increased pain when compared to sternotomy. Adequate pain relief during this time is essential [19]. Regional analgesia plays an important role after thoracotomy in addition to regular paracetamol and patient controlled opioids. The following nerve blocks are useful and can be effective adjuncts:

- Thoracic epidural
- Paravertebral continuous infusion with surgically placed catheter under direct vision.
- Intercostal nerve blockade
- Continuous intercostal nerve blockade
- Extra-pleural catheter and continuous local anaesthetic infusion

CONCLUSION

MIMVS presents a change in approach for the anaesthetist. As well as different surgical equipment and technique, an alteration in the equipment and approach for the anaesthetist is required. The two main differences are the instigation of one lung ventilation before and after CPB and the increased reliance on the TOE for both MV assessment and placement of CPB equipment. To yield maximum gain from MIMVS, the anaesthesia and surgery itself must form part of a comprehensive package of peri-operative care that delivers high standards throughout the patient care pathway.

Chapter 418

MINIMALLY INVASIVE APPROACHES TO MITRAL VALVE SURGERY

Kasra Shaikhrezai and Steven Hunter*

Chesterman wing, Northern General Hospital, Sheffield, UK

ABSTRACT

The emerging technology and the advent of the endoscopic camera revolutionised cardiac surgery introducing a novel and less invasive approach. Minimally invasive mitral valve surgery is now performed via mini-thoracotomy or port access, limited sternotomy and robotic surgery. The minimal invasive approach starts in the anaesthetic room and continues throughout the procedure. Exposure, cannulation, myocardial protection and the mitral valve are the cardinal targets of this approach. A rehearsed and well-planned approach at each stage will facilitate the smooth conduct of the operation and its progress from one stage to another. This shortens the learning curve and brings most of the procedure into the surgeon's comfort zone. The evolving technology is constantly changing and improving the current minimal invasive practice to create much less invasive approaches. Surgeons need to remain updated at all time and adopt new technology in favour of patient care and better outcomes. There are several ways of performing minimally invasive mitral valve surgery and it is the surgeon's task to set out a road map and strategy for each operation, which is always different from the last one.

Keywords: surgical approach, minimal invasive surgery, mitral valve surgery

INTRODUCTION

In Germany Eric Muhe and his colleagues performed the first laparoscopic cholecystectomy more than 30 years ago [1]. The described procedure revolutionised cholecystectomy however it took a fairly long-time to adopt the approach as the gold standard procedure. The evolving technology shortened the dormant period and new surgeon-friendly

* Corresponding Author's Email: steven.hunter@sth.nhs.uk.

instruments brought the approach into the surgeons' comfort zone. In our day laparoscopic cholecystectomy, which was once deemed as a fictional fantasy, is performed safely as a day-case operation. More than a decade later, Alain Carpentier performed the first successful minimal invasive mitral valve (MV) operation in man [2], which surgically and anaesthetically was a more demanding operation [3]. Twenty years on the minimal invasive approach has yet to become the gold standard for MV surgery in many institutions. In the United Kingdom since 2009, the number of isolated MV surgery has significantly increased to more than 2,300 cases per year in 2013 [4]. Although the outcome of MV surgery has improved nationwide during the past decade, a minimal invasive MV program is only run in a small number of institutions across the UK. In fact, the practice is quite skewed in Europe; in Germany alone the minimal invasive approach is considered as the first choice for nearly half of the isolated MV procedures [5]. The discrepancy is a multifactorial with a wide spectrum of confounding factors from logistical and technological setback to complex learning curve and adaptation problems. In many experiences a prolonged tortuous learning curve has been considered to be detrimental to the development of young programs. Centralisation of minimal invasive practice, which leads to the creation of high volume centres, has been proven to be a solution to this problem [6]. The difficulty in using single shafted instruments for minimal invasive mitral valve surgery (MIMVS) can be lessened by frequent handling of these instruments in cases via a median sternotomy approach [7]. Program failure may be largely attributed to a breakdown in the axis of team working – communication – performance. Young programs are vulnerable to demise at an early stage if the program is not set up and governed prudently. Teamed surgeons, full interaction with the anaesthesiology team and constant equipment check facilitate the smooth progress of the program. More importantly the surgical team should be aware of their limitations and overcome their ego at all stages of the program. The surgeon can start with a 10 to 12cm incision and consider staged reduction of the incision size as the program moves forward with good results. It is imperative to start the program with straightforward MV repairs (MVr) which allows the team to familiarise themselves with the set up. In addition, easy cases may create more comfort zones for the surgeon who is at the beginning of his learning curve. "Approach" terminology in minimal invasive surgery has a broad definition, which ultimately mandates the medical and surgical strategies from bed to table. There are multiple approaches at different levels of MIMVS, which need to be adopted as per individual cases of MV disease. A wisely chosen approach will shorten the learning curve and is pivotal to the survival of the program in providing the best treatment and care for the patients.

APPROACH

A comprehensive approach embraces crucial domains of a minimal invasive mitral valve surgery program, which can be categorised as: Exposure, Cannulation, Myocardial protection and Mitral valve.

Exposure

Positioning

Surgeons should not underestimate the importance of positioning in anaesthetic room. This obviously has already been confirmed at the briefing and all members of the team should familiarise themselves with the positioning of patient. The patient's right chest needs to be tilted up at a 30 degree angle with the table. The right arm should be extended at 45 degree with the elbow flexed at 90 degree resting on an arm board. This manoeuvre is the first important step for a desirable surgical exposure. At this stage the inguinal area (usually on the right side) needs to be scanned by ultrasound to make sure the femoral vessels are of good quality and acceptable calibre for cannulation, irrespective of pre-operative CT scans. Our minimum cut-off for femoral artery is 8 mm in diameter. Obviously any abnormality of femoral vessels such as localised dissection or calcified plaques will be a contraindication for femoral cannulation.

Thoracic Surgical Exposure

There are two main surgical minimal invasive approaches to MV surgery: limited incision on the sternum and limited incision on the right thoracic wall known as port access surgery. There are numerous concepts on how to establish the exposure as least invasive as possible. The sternotomy approach includes an upper limited sternotomy, which usually requires a trans-septal approach to the left atrium [8] and lower limited sternotomy, which is accompanied by an incision through the Sondergaard groove [9]. Although both approaches have succeeded to provide a good exposure as well as an acceptable cosmesis, the port access approach gained popularity as a standard approach in the field of MIMVS [10]. Therefore, in this chapter, we will be more focused on port access approach. As per our definition a port access approach includes a 4 – 5 cm right sub-mammary mini-thoracotomy with soft tissue retraction only. Rib spreading and using of a rib retractor will automatically disqualify an operation to be registered as port access MV surgery, however it is recommended to start the program with larger than 5 cm incision and occasional use of a mechanical rib retractor [7]. The incision size and abandoning the rib spreading techniques can be optimised when a surgeon is fully comfortable with the exposure. Generally, the chest exposure is categorised into external and internal exposure. For external exposure the incision is usually in the 4th intercostal space (ICS), however it may vary between patients with different chest anatomy. After performing the incision and applying the soft tissue retractor surgeon needs to use his index finger to check the distance from diaphragm, which may require the extension of initial incision for another 1 – 2 cm in lateral or medial direction. We usually use a 10 mm, 30 degree, 3D camera, which is inserted through a port with CO₂ connection in the same intercostal space as the main incision and 2 – 3 cm lateral to it. The camera holder is attached to top right-hand side of the table and will keep the camera steady throughout the procedure. A Sump sucker is inserted through a 4mm stab incision two to three spaces below the incision, which will be one of the drain locations at the conclusion of the operation. The left atrium (LA) retractor is inserted through a 3 mm stab incision in same intercostal space as the main incision 4 – 5 cm away from sternum. The surgeon should take extra care during the insertion of the LA retractor as this may injure the right internal thoracic artery. This is achieved by using the thoracoscope to visualise the inside of the chest wall and the course of

the internal thoracic vessels. A sternal wire is passed through a large bore needle above the main incision and is brought through the main incision and clipped. This is a crucial step as the mitral annular stitches at A_1 and P_1 location will be in front of the camera and hamper the view. If aortic occlusion is to be performed by a transthoracic aortic cross-clamp (AoX), this needs to be inserted one ICS above the camera port. At this stage the clamp must be tested to make sure that the grip and occlusion is satisfactory. All the above steps are demonstrated in Figure 1.

For internal exposure initially the pericardium is opened transversely between inferior vena cava (IVC) and superior vena cava (SVC). Pericardial retraction plays an important role in a desirable exposure. Sometimes it is inevitable to look through the incision rather than using the camera, for example in pericardiotomy and applying traction sutures; however, it is recommended to use the camera and the front screen as much as possible. The pericardial traction sutures are usually three and the sutures are taken out and affixed to the chest through the following holes: 1- Sump sucker hole (below the incision) which retracts the posterior border of pericardiotomy inferiorly 2- Camera port (below the incision) which retracts the posterior border of pericardiotomy superiorly. The third traction suture is placed in the anterior border of pericardiotomy and is brought through the main incision without cutting the needles. The latter traction suture will be used, following the left atriotomy, to retract the anterior border of atriotomy. Following institution of cardiopulmonary bypass (CPB) and administration of cardioplegia the final stage of internal exposure is the left atriotomy through the Sondergaard groove (Figures 2 and 3) and retracting the atriotomy (Figure 4).

Figure 1. External thoracic exposure, A: Incision and soft tissue retractor B: Camera and the port with CO₂ entry valve C: Sump sucker (future drain location) D: Left atrium retractor E: Sternal wire as annular stitch retractor F: Transthoracic clamp known as the Chitwood clamp.

Figure 2. The Sondergaard groove (arrow).

Figure 3. A: Forceps holding the upper border of the groove B: size 11 blade C: Sump sucker ready to be inserted into the atriotomy.

Inguinal Surgical Exposure

We believe that if the MV surgery is straightforward with no concomitant procedure prolonging the operation, femoral artery cannulation is less invasive with acceptable flow during the CPB. It is imperative to scan the inguinal area prior to operation and mark the incision site.

There are two approaches to femoral vessels cannulation: percutaneous and incisional. In percutaneous approach the cannulation of femoral vein and artery is performed contralaterally. The key instrument to cannulate the femoral artery is The Prostar (Abbott Vascular, Abbott Park, IL, USA) which is a closure device. Following venous decannulation and administration of protamine, temporary manual pressure would suffice to stop the bleeding. Femoral artery decannulation and application of Prostar requires a minimum of 24 hours compression on the cannulation site with pneumatic compression devices.

Figure 4. Final internal thoracic exposure: T: Trigone, AMVL: Anterior Mitral Valve Leaflet, PMVL: Posterior Mitral Valve Leaflet.

Figure 5. Surgeon's view of inguinal incision: A: Femoral vein purse string, B: Femoral artery purse string, C: Femoral artery and the cannulation site surrounded by four pledgets. The femoral vein should not be denuded and a small area of dark blue would suffice to insert the needle, guide wire and cannula (arrow).

The percutaneous cannulation has been proven to be safe with less inguinal wound complication [12]. During incisional approach it is imperative to expose the femoral sheath. Therefore the 3cm incision should not be on the inguinal crease, which may limit the exposure and miss the femoral sheath. The incision should be on the inguinal ligament, which is invariably superior to the crease. After fat dissection the retractor is positioned then and the

index finger is used in a sweeping manoeuvre is to clearly expose the inguinal ligament superiorly as well as femoral sheath inferiorly. Following a T incision on the femoral sheath the vessels will be sufficiently exposed underneath. It is recommended not to denude the femoral vein as the tissue surrounding the vein plays a role in haemostasis after femoral vein decannulation (Figure 5.). As mentioned previously we believe that not all diameters are suitable for femoral artery cannulation therefore our threshold is 8mm of the internal diameter. Sometimes the arteries are constricted masking the true size of the lumen in these cases we use a swab soaked in nitroglycerin, which will be packed into the inguinal wound for few minutes while the operation is progressing at the chest. We use two pledgeted CV5 GORE-TEX (W.L. Gore, AZ, USA) sutures as the femoral artery purse strings. The sutures are placed longitudinally with four pledgets defining the cannulation area (Figure 5). This minimal dissection of the femoral vessels decreases the chance of post-operative lymphocele formation.

Cannulation

Although in many minimal invasive programs, the inguinal approach for both arterial and venous cannulation has been adopted as a routine practice, there are different approaches for cannulation and institution of CPB. Arterial cannulation can be performed directly on the ascending aorta with antegrade flow or on femoral artery with retrograde flow. Femoral artery cannulation is considered a less invasive approach with good control of cannulation site following decannulation. Direct cannulation of ascending aorta requires an extra hole in the chest or it may hamper the exposure. Large bruises on a fragile aorta are another shortcoming of direct ascending aorta cannulation, which may cause a some difficulty following decannulation and repair of the cannulation site. On the other hand, prolonged operation with femoral artery cannula and retrograde flow may cause ischaemia of the lower limb and deleterious shear stress and sand blasting effect on the arterial wall. Although there is no randomised trial comparing these two cannulation techniques, large cohorts have demonstrated that both approaches are acceptable with good results [11, 12]. Cannulation of the ascending aorta should be performed with extra care and usage of pledgeted sutures. During decannulation the inner purse string is best secured by Cor-Knot (LSI Solutions, NY, USA) and the outer purse string can be tied with a knot pusher. A routine over-and-over stitching of the cannulation site is also recommended to reduce the risk of dissection.

As a general rule, with the inguinal approach, the femoral vein is cannulated first followed by femoral artery. The venous cannula is a standard two-stage cannula which must be positioned carefully with the holes in the IVC, right atrium (RA) and SVC. Femoral vein cannulation can be disastrous and the surgical team should have a clear routine for cannulation with the help of the surgical scrub nurse. This requires pre-operative rehearsal and equipment check. If the needle after insertion into the dark blue area (Figure 5) did not aspirate enough blood do not be discouraged as patient might be hypovolaemic. Transoesophageal echocardiography (TOE) is an important adjunct to the operation by which the correct position of the wire in IVC – SVC view is confirmed. Cannula insertion does not always require pre-dilatation therefore surgeons should be cautious not to push the cannula in over the guide wire if there is any resistance. Always wet the cannula with a swab as this facilitates the insertion through the vessel wall. With the IVC – SVC view the cannula

location can be confirmed by TOE, at this stage the surgeon withdraws the trocar and the guide wire; the cannula holes in SVC and the RA can be clearly counted. This manoeuvre is our gold standard for confirmation of desirable cannula position (Figure 6).

Surgeons need to aware that while the LA is retracted after the atriotomy, the tip of the venous cannula if not in the right position or not well-advanced, may be pulled out of SVC. The mitral retractor occludes the SVC impeding the venous drainage. This manifests itself by a sudden rise in central venous pressure. Femoral artery cannulation requires 3-4 incremental dilators. It is recommended to insert the cannula with wrist rotating similar to handling a screw driver. In the event of using an endoballoon, the insertion of an antegrade cardioplegia cannula into the ascending aorta would not be necessary. In this situation the femoral artery cannula has a side arm, which allows the insertion of the endoballoon following cannulation of femoral artery (Figure 7). The surgeon should make sure that the side arm stays towards the surgeon (the right side of the artery).

Figure 6. Femoral vein cannulation demonstrated by SVC (Superior Vena Cava) – IVC (inferior Vena Cava) TOE (Transoesophageal echocardiography) view. The distal cannula holes are demonstrated (arrows).

Figure 7. The side arm of the femoral artery cannula (arrow) containing the endoballoon with the blue locker cap visible at the tip of the side arm.

Figure 8. SVC cannula.

If there are concomitant procedures requiring access to RA (tricuspid valve surgery, atrial septal defect, cardiac tumors and Cox Maze IV) the cannulation strategy needs to be on the basis of separate cannulation of SVC and IVC. For these procedures the anaesthetist will cannulate the SVC before draping the patient (Figure 8).

Figure 9. Insertion of a long antegrade cardioplegia cannula into the ascending aorta.

If a transthoracic clamp is used with femoral vessels cannulation, a long antegrade cardioplegia cannula needs to be inserted into the ascending aorta for the delivery of the cardioplegia (Figure 9).

Because the cardioplegia cannula is thin it is possible to pass it through the main incision without the need to create a new hole in the chest wall. It does not affect the view or exposure. As explained previously for direct ascending aorta cannulation it is safe to use pledgeted sutures and secure the first purse string with Cor-Knot after removing the antegrade

cardioplegia cannula. This decannulation needs to be done prior to femoral decannulation while patient is still on CPB. Femoral decannulation must be performed when all checks with the perfusionist and anaesthetist are done including TOE images confirming a good mitral valve repair. Decannulation always starts with the femoral vein cannula followed by the femoral artery cannula after administration of protamine. Femoral vein cannulation site usually does not require over-sewing particularly if the vein is not denuded. Following femoral artery decannulation, the CV5 sutures are tied and the ridge of the cannulation site is over sewn with a running suture. Groin compression following this technique, is not required.

Myocardial Protection

MIMVS and in particular the port access approach has been recognised as an operation with longer CPB and AoX times compared to conventional surgery via a median sternotomy [13]. Despite the longer ischaemic time, there are several studies confirming that port access approach is associated with favourable results and satisfactory post-operative course [14, 15, 16, 17, 18, 19, 20]. As a general principle all protection strategies such as beating heart and ventricular fibrillation used in sternotomy cases can be deployed in port access surgery. It has been demonstrated that ventricular fibrillation with cooling and beating heart surgery have provided satisfactory myocardial protection in complex redo cases of MIMVS where conventional approaches to myocardial protection were too difficult or not possible [21]. At present there is a consensus to use cardioplegia solution in order to achieve diastolic myocardial arrest as the gold standard approach [22]. The cardioplegia solutions have significantly evolved through time providing a better myocardial protection in the modern era of cardiac surgery [23]. There is no consensus on the type of cardioplegia used for port access approach. Because in the United Kingdom some solutions are not yet licensed, we use hyperkalaemic cold blood cardioplegia with a loading dose followed by maintenance doses every 20 minutes. In Germany, crystalloid Bretschneider solution has gained popularity and is used in MIMVS which provides the surgeons with 120 minutes window period between the loading dose and the next maintenance dose [17, 24]. The current practice of hypothermia is also quite skewed where the hypothermic protection varies from a simple temperature drift to run the CPB at 30-32 degrees C [17, 22]. Delivery of cardioplegia in port access MV surgery is antegrade with two main routes of administration; cardioplegia cannula inserted into the ascending aorta or cardioplegia delivered through the lumen of an endoballoon. Either of these can be combined with retrograde coronary sinus cardioplegia. The latter is administered through a cannula that can be placed via the right internal jugular vein using TOE guidance. The deployment of the endoballoon requires specific consideration. The endoballoon is a multi-purpose device, which provides aortic occlusion as well as delivery of cardioplegia and venting of the aortic root. The design of the endoballoon started before the first MIMVS was performed in humans [25] but soon became a less invasive and safe method for administration of cardioplegia and aortic occlusion [26, 27, 28]. A pre-operative contrast chest and abdomen CT-scan is advised, especially, if an endoballoon is to be used. The large diameter of ascending aorta more than 38 mm would be in favour of transthoracic occlusion and not using the endoballoon. It is also safer not to use endoballoon if the patient has large calcified plaques in the aorta, pulmonary hypertension, right ventricle failure or poor ejection fraction. The device needs to be de-aired and prepared while patient is still in the anaesthetic room. All

the staff should receive training on how to prepare the endoballoon. The device contains multiple channels, which need to be monitored by the perfusionist, the anaesthetist and the surgeon (Figure 10). The perfusionist's end will be used for monitoring the balloon pressure (around 400 mmHg), running cardioplegia and venting the aortic root. The anaesthetist monitors the aortic root pressure and both right and left radial pressures. The surgeon with the help of the scrub nurse has control over handling the built-in guide wire for positioning the balloon and balloon inflation for aortic occlusion.

Figure 10. Endoballoon kit and the balloon occluding aortic (arrow).

The endoballoon is inserted through a side arm on the femoral artery cannula. When the balloon is still in the femoral artery cannula the guide wire is advanced and the location is confirmed by TOE with a descending aorta view. The guide wire with the appropriate TOE window is positioned in the ascending aorta. Then the device is driven over the wire until it reaches the ascending aorta, which is confirmed by TOE. The guide wire is withdrawn. The balloon is inflated with TOE guidance to optimise the position (1cm distal to the sinotubular junction). The device is locked when the desirable location is achieved. It is important to monitor the cardioplegia delivery on TOE images, which provides conformation of the safe delivery with no balloon displacement. All patients with the endoballoon should have an arterial line placed in right and left radial arteries. Migration of the balloon during cardioplegia delivery may occlude the right brachiocephalic artery. This occlusion is confirmed by damping in the right radial artery trace which requires TOE-guided repositioning of endoballoon. In some cases, the LA retractor may tent up the right coronary artery with temporary occlusion and also may cause aortic regurgitation. It is recommended to loosen the retractor while delivering the cardioplegia. In the event of mild aortic regurgitation we advocate a manoeuvre to overcome this problem in our practice. The manoeuvre constitutes the placement of a curved clamp through the transverse sinus with a gentle pressure towards the posterior aortic annulus. In our experience this manoeuvre significantly reduces the regurgitation, which can be easily observed through the mitral valve or by TOE images. Moderate aortic regurgitation is a relative contra-indication for MIMVS. Balloon rupture is a rare complication but the surgeon and his team should be prepared to deal with

this complication. Hard, calcified plaques or deep annular suturing at A1 area may rupture the balloon. The perfusionist reports a sudden drop in balloon pressure and the surgical field will be flooded with blood. In this situation particularly when LA is open, heart contractility may lead to catastrophic air emboli if the mitral valve is competent. Therefore, in all endoballoon cases, a transthoracic clamp and fibrillator must be available in theatre at all time. The best course of action following balloon rupture when LA is open would be ventricular fibrillation. This manoeuvre provides more time to establish a proper transthoracic occlusion.

Mitral Valve

The principles of approach to MV surgery remain similar to those of the conventional median sternotomy approach and are beyond the focus of this chapter. Surgeons should not try to change the MVr techniques that they have already adopted in conventional surgery while embarking on minimal invasive program [7]. All valve repair techniques such as triangular resection, neo-chordae attachment (Figure 11), chordal transfer and commissuroplasty are reproducible in minimal invasive setting with satisfactory outcomes [15, 17, 29]. It also has been demonstrated that port access MVr in complex cases such as Barlow's MV disease in large volume centres is associated with satisfactory results [30].

We believe that the foundation of a desirable MVr is proper annular plication. The plication requires an accurate suturing without damaging the adjacent structures. Proximity of coronary sinus and circumflex artery to the annulus may result in damage these structures during the annuloplasty or interrupted sutures for MV replacement. In order to avoid these complications and to optimise the visualisation we advocate switching to 3D mode of camera while suturing the annulus. One of the critical approaches to annular suturing with single shafted instrument is needle positioning. Fine hand movements tend to be exaggerated at the tip of the instrument because of the long shaft, which may create jerky needle shots. We have adopted an all-backhand approach to mitral annulus suturing. In this technique nearly all shots are performed by a needle, which is mounted backhand on the needle holder (Figure 12). The needle insertion site should be on the annulus however the backhand shot will drive the needle towards the LV and then back through the annulus into the LA. This manoeuvre almost guarantees the structures adjacent to the annulus will not be damaged. We usually use incomplete rings for annular plication and the sutures will be secured using Cor-Knot.

Figure 11. Attachment of neo-chordae to posteromedial papillary muscle.

Figure 12. Backhand needle shot for annuloplasty suturing.

We have recently moved on from saline test to check the valve competency prior to atriotomy closure. For this a fine rubber catheter is attached to the cardioplegia line and placed in the left ventricle through the MV. The perfusionist starts to administer the blood cardioplegia while the root vent is stopped until the left ventricle is full. Usually the LV is well pressurised with 120 to 150 ml cardioplegia demonstrating a desirable repair (Figure 13). This manoeuvre also plays a role in final de-airing prior to closure of the atriotomy.

Figure 13. Mitral valve repair tested by blood cardioplegia. The sutures clipped down by Cor-Knot are visible across the incomplete ring.

Robotic Technology

The robotic approach to MVr started to evolve in late 1990s just a few years after the first minimally invasive MV operation [31]. Satisfactory results have been reported for the robotic approach, which in practice uses the port access approach principles [32, 33]. The robotic

approach requires more time to gain popularity as the primary approach to MV surgery. This is probably due to the costs, availability and training. This is discussed in more detail in another chapter.

CONCLUSION

MIMVS has rapidly progressed to become a safe modern operation offering one of the best treatments for MV disease. Port access surgery as one of the most recognised approaches constitutes several steps and phases. There are multiple instruments for each phase of the operation, which necessitates training for all the surgical and non-surgical team members prior to starting a program. On the other hand there are multiple approaches at different levels of the operation, which have been proven to be safe and reproducible in large published cohorts. The surgical team should be familiarised with all of these alternative approaches, as this would provide more options when the usual approach is not possible. TOE is a precious adjunct and surgeons need to master the interpretation of the images, which have a profound effect on planning and choosing the right approach. This also facilitates the learning curve while having more options on board automatically creates peace of mind. The rapid advance of technology is introducing new horizons and approaches to perform the operation as least invasive as possible. In the world of minimal invasive cardiac surgery the future is everyday!

Chapter 419

CANNULATION AND CARDIO-PULMONARY BYPASS FOR MINIMALLY INVASIVE MITRAL VALVE SURGERY

M. Pozzi* and J. F. Obadia

Department of Cardiac Surgery, “Louis Pradel” Cardiologic Hospital,
“Claude Bernard” University, Lyon, France

ABSTRACT

A growing number of technological improvements have made minimally invasive mitral valve surgery (MIMVS) safe, easier and routinely performed in several experienced centers. Different cannulation techniques have been used over time in the specific setting of MIMVS. Direct aortic cannulation could represent a possible option to institute cardiopulmonary bypass. Moreover, femoral vessel cannulation has been progressively performed through smaller incisions and minimal dissection limited to the anterior face of the vessels. More recently, percutaneous femoral vessels cannulation became possible using closure devices with several potential advantages. Myocardial protection is of utmost importance in the outcome of MIMVS patients but the optimal cardioplegic solution remains still controversial. Some authors also suggested to perform MIMVS on a beating or fibrillating heart when aortic cross clamping is not technically feasible. So, the aim of the present chapter is to offer a description of our cannulation technique in MIMVS.

Keywords: complications, femoral artery, mitral valve, minimally invasive, percutaneous

INTRODUCTION

Minimally invasive mitral valve surgery (MIMVS) using various approaches was first performed in the second half of the 1990s by different surgical teams [1-3]. Then, a growing

* Corresponding Author's Email: mpozzi1979@gmail.com; Fax: +33472357383.

number of technological improvements have made MIMVS safe, easier and routinely performed in several experienced centers. Moreover, it has become the first-line surgical approach to treat mitral valve (MV) diseases in various centers [4, 5].

Different cannulation techniques have been used over time in the specific setting of MIMVS. Direct aortic cannulation could represent a possible option to institute cardiopulmonary bypass (CPB). Moreover, femoral vessel cannulation has been progressively performed through smaller incisions and minimal dissection limited to the anterior face of the vessels. More recently, percutaneous femoral vessels cannulation became possible using closure devices with several potential advantages. Percutaneous femoral vein cannulation is technically easy and already widely used in many surgical and interventional procedures. On the arterial side, the closure of the vessel is more difficult, requiring a specific closing device. Prostar (Abbott Vascular, Abbott Park, IL, USA), a percutaneous arterial access closure device, consists of a sheath containing four needles connected to two braided sutures. It has proven to be safe and effective in the setting of endovascular treatment of thoracic and abdominal aortic aneurysms [6-8] and transcatheter aortic valve implantation [9-11]. Our surgical team has already reported its application in the setting of MIMVS [12].

Myocardial protection is of utmost importance in the outcome of MIMVS patients but the optimal cardioplegic solution remains still controversial. Some authors also suggested to perform MIMVS on a beating or fibrillating heart when aortic cross clamping (AoX) is not technically feasible [13, 14]. The primary aim of the present chapter is to offer a description of our cannulation technique in MIMVS.

PREOPERATIVE EVALUATION

Preoperative evaluation starts with a meticulous history and a careful physical examination (in particular femoral arterial pulse). The history of the patient and chest x-ray evaluation should search for the presence of right pleural adhesions. Doppler ultrasound evaluation of the femoral vessels is no more performed on a routine basis but only if indicated by the physical examination. The presence of lower limb arteriopathy represents a formal contraindication to peripheral CPB. Preoperative echocardiography should detect possible aortic regurgitation, which could undermine myocardial protection with antegrade cardioplegia. Finally, diagnostic coronary angiography must be ideally performed through the radial artery in order to preserve femoral approaches. In young patients a non-invasive assessment of the coronary arteries by computed tomography (CT) is also an excellent option. Patients with MV disease are so operated in accordance with the current recommendations [15].

PATIENT PREPARATION AND POSITIONING

After conventional anaesthesia, a single-lumen intubation is introduced. Double-lumen intubation was systematically performed at the beginning of our experience but now it is used only in case of concomitant atrial fibrillation (AF) ablation in order to reduce CPB duration. The patient is positioned in supine decubitus with a gel bolster under the shoulders. The right

arm is slightly folded with the palm of the hand looking at the table (figure 1). Defibrillation paddles are placed on the back of the patient.

Figure 1. Patient positioning.

Asepsis is aimed to expose two surgical zones: the groins and the right chest with the sternum. The sternum must always be kept in the sterile zone in order to allow for conversion to a full sternotomy if needed. The sterile adhesive films are settled in order to pull up the breast and so to lift the inframammary groove in front of the fourth intercostal space (ICS). A 10mm 30° endoscope is installed and connected to the self-retaining Endoboy arm.

FEMORAL VESSEL CANNULATION

CPB is instituted through the cannulation of the femoral vessels with total percutaneous approach. This cannulation technique has been previously described [16]. Our technique begins with arterial cannulation. Infra-inguinal puncture carefully targets the anterior wall of the mid-common femoral artery before venous cannulation to avoid arterial puncture under systemic heparinization. In our opinion ultrasound-guided femoral artery puncture could be helpful in complex cases like severe obesity but is not necessary on a daily basis.

A guidewire is introduced and the correct position verified in the descending aorta with transesophageal echocardiography (TEE). Heparin is administered into the patient. Blunt dissection of the subcutaneous tissue all the way down to the femoral artery with a mosquito clamp is of utmost importance to allow a perfect introduction of the Prostar (Abbott Vascular, Abbott Park, IL, USA; figure 2).

Subsequently, an arterial cannula (usually 17 Fr; Maquet, Orleans, France) is inserted. The percutaneous venous cannulation is performed on the contralateral side (usually the right) to reduce the risk of arterio-venous fistula (figure 3).

Figure 2. Introduction of Prostar.

We utilize a 23/25 Fr two-stage single cannula (Estech Inc., Danville, CA, USA) placed up to the superior vena cava (SVC) using TEE guidance, with satisfactory venous drainage achieved using a centrifugal pump (Medtronic Biomedicus, Eden Prairie, MN, USA). The percutaneous cannulation of the right internal jugular vein was performed only at the beginning of our experience.

Figure 3. Total percutaneous femoral vessels cannulation with the arterial cannula on the left side of the patient and the venous cannula on the right side.

SURGICAL TECHNIQUE

The surgical access is represented by an anterolateral right minithoracotomy (3-5 cm) at the fourth ICS. The optic is introduced in the same ICS at the level of the mid-axillary line. The soft tissue retractor is inserted over the insufflating CO₂ line (flow of approximately 2 l/min without pleural pressure control) (figure 4). CPB is commenced before opening the pericardium at the theoretical flow according to patient's body surface area. The ventilation is then stopped. The pericardium is so opened and exposed by two or three stitches while a transparietal stitch retracting the diaphragm is used only if necessary. The SVC and inferior vena cavae (IVC) are mobilized in order to facilitate the atriotomy subsequently and, if needed, to place the radiofrequency belt necessary for the AF ablation. A 3/0 polypropylene U-shaped purse string is realised on the ascending aorta.

Figure 4. Right anterolateral minithoracotomy (3-5 cm) in the fourth intercostal space. 1 = percutaneous left atrium retractor, 2 = soft tissue retractor, 3 = CO₂ line, 4 = left ventricular vent line, 5 = optic, 6 = cardioplegia cannula.

Figure 5. Aortic cross-clamping.

The cardioplegia cannula is placed on the ascending aorta and connected to the cardioplegia line. In our institution we utilize cold crystalloid cardioplegia for every type of minimally invasive MV operation. A transthoracic clamp is inserted through the fifth ICS in the mid-axillary line and directed toward the transverse sinus (figure 5). It is of paramount importance to check that the distal part of the transthoracic clamp does not engage the left atrial appendage. Specific, long-shaft surgical instruments are introduced through the soft tissue retractor. The left atrium (LA) is opened through the interatrial groove during the administration of the cardioplegia in order to unload the left ventricle (LV). One or two Ethibond 2/0 stitches are used to pull the upper portion of the atriotomy. A left atrium retractor is placed through the fourth ICS in the mid-clavicular line and then the left ventricular vent is positioned in the superior right pulmonary vein. The quality of this video-assisted approach allows performing either different repair techniques specifically addressed to the anterior and posterior leaflet or MV replacement. At the end of the MV operation, the LA retractor is removed and the LA is closed by two 3/0 polypropylene running sutures. The AoX is also removed after purge manoeuvres and deairing is accomplished through the cardioplegia cannula which is now an aortic root suction line. Epicardial pacing wires are placed on the anterior face of the right ventricle (RV) and it is strongly suggested to place them on CPB with an unloaded RV. TEE finally checks the quality of the deairing, optimal filling conditions, RV and LV function and the result of MV operation.

DECANNULATION

After weaning from CPB, the venous cannula is removed first. Local haemostasis is obtained with a simple skin stitch and manual compression on the right groin.

On the other side, after protamine administration, the left femoral cannula is removed and artery closure is assured by pulling down the two braided sutures of the Prostar (figure 6).

Figure 6. Percutaneous arterial hemostasis assured by Prostar device.

During this manoeuvre, it is very important to irrigate the sutures in order to help slide the knot down. A 24-hour compression was applied on both sides. Intrathoracic haemostasis is carefully controlled before removing the endoscope. Two 24 French thoracic drains are positioned through two different ports: the pleural drain through the optic port and directed to the posterior and lower part of the right pleural cavity and the pericardial drain through the AoX port towards the lateral face of the LV. Finally, the pericardium is closed, the ICS is approximated, superficial planes are closed in routine manner and local, long-acting anaesthesia is infiltrated before wound dressing.

CONCLUSION

Total percutaneous femoral vessels cannulation technique is particularly suitable for MIMVS with a high success rate and few complications after a short learning curve. With the advent of this percutaneous approach, the traditional complications of the groin incision have completely disappeared in modern operations with no groin infection, haematoma or lymphocele.

Chapter 420

MINI-STERNOTOMY MITRAL VALVE SURGERY

Ludwig C. Müller*

Department of Cardiac Surgery, Medical University,
Innsbruck, Austria

ABSTRACT

A minimally invasive approach to the mitral valve nowadays is increasingly becoming the procedure of choice for mitral valve surgery. If, however, a right mini-thoracotomy and video assisted mitral valve surgery is contraindicated or in cases when simultaneous aortic valve replacement ($\pm$ tricuspid surgery) is necessary, upper hemisternotomy is a valuable and safe alternative. Indications, technique and results are delineated in this chapter.

Keywords: mitral, ministernotomy

INTRODUCTION

Since introduction of video-assisted surgery for mitral valve (MV) operations, right mini-thoracotomy has evolved as the most used access route by surgeons and in centers interested to reduce incisional size and thereby surgical trauma. In 2014 in Germany, 45% of isolated MV surgeries were performed through this approach [1]. However, these numbers were treated mainly in few high volume centers. As the intricate technical aspects of this technique may not be solved properly in lower volume centers and/or by lower volume surgeons, many still rely on full sternotomy to operate on the MV. Furthermore, there are patients in whom the mini-thoracotomy approach may be contraindicated or at least not recommendable. Finally there are still well renowned surgeons with excellent technique and results who find the mini-thoracotomy approach not well suited for their surgical requirements [2]. In all of these situations there is still an option for reduced surgical trauma by avoiding full median

* Corresponding Author's Email: ludwig.mueller@i-med.ac.at.

sternotomy with the promise of shorter recovery and of course better cosmesis which should be preferably addressed as superior preservation of body integrity. Upper hemisternotomy (UHS) provides excellent access to the MV and of course also to the aortic (AoV) and tricuspid valves (TV) as well as to the main stem of the right coronary artery in case a single bypass to this vessel is required.

TECHNIQUE

The patient is positioned in a supine position as for median sternotomy and a longitudinal skin incision usually 8-10 cm long originating from two centimeters below the sternal notch to the level of the 4th intercostal space is performed (figure 1). Attention must be given to identification of the correct intercostal space (ICS). Then a midline sternotomy is performed from the sternal notch downwards into the left ICS using a common jigsaw like in full sternotomy. To avoid sternal fracture, it helps to softly curve the sternotomy into the 4th ICS (figure 2). After insertion of a small thoracotomy retractor, the procedure is continued as usual. Pericardiotomy is performed as an inversed T and multiple - usually 6 - pericardial stitches are used to fix the pericardium to the skin. The thoracotomy retractor is repositioned within the pericardium. Exposure is still very limited and concern may arise if the MV would be approached properly. It will!

Figure 1. Skin incision.

Figure 2. Upper hemi-sternotomy.

After full heparinisation the ascending aorta is cannulated in standard fashion and the superior vena cava (SVC) is cannulated using a 22 Fr right angled venous cannula with a short leg. After connection to the tubing ECC can be started. IVC cannulation may be performed at this time using a 24 Fr straight cannula through the right atrium (RA). Alternatively (our preferred practice) femoral venous cannulation is employed. The right femoral vein is cannulated using Seldinger's technique with a 21-25 Fr femoral venous cannula. A two-staged femoral venous cannula (Livanova RAP cannula) may also be used to avoid any venous cannulae in the limited working space. When the heart is fully emptied and the lungs are deflated, exposure now inspires much more confidence to address the MV properly. A soft venting catheter is inserted into the left atrium (LA) via the right superior pulmonary vein. The caval veins can be encircled easily using vessel loops and the aorta is crossclamped and antegrade cardioplegia is given. After installation of total CPB, the RA is opened longitudinally and kept open with two stay sutures (4-0 polyethylene). If required, a coronary sinus catheter for retrograde application of cardioplegia is inserted and fixed with a 4-0 purse string suture within the coronary sinus ostium. The interatrial septum is incised at the level of the fossa ovalis and the incision extended into the roof of the LA to the desired level (figure 3). Care should be taken not to hit the posterior left atrial wall since due to suction the LA is collapsed. Most times division of the sinus node artery is not avoidable. At this point one must care to incise the LA not too close to the MV, otherwise exposure will be difficult. A 2 cm distance should be respected. Pledgeted mattress sutures right at the junction of the right and left atrial wall with the interatrial septum keep the LA open and later help at reconstruction of the septum and the LA. While the table is elevated head up and slightly rotated to the left, the MV is exposed by the assistant using two small (peanut) sponge sticks (figure 4). Up to now, no suitable mountable retractor for valve exposure is known to the author. Alternatively, the trans-septal approach through the roof of the LA is a viable solution. This may be the preferred access when simultaneous aortic valve replacement is needed. The ascending aorta is transected immediately above the sinotubular junction and the LA is entered without opening the RA and/or damaging the sinus node artery. Exposure of the MV is accomplished by the use of two sponge sticks.

Figure 3. Trans-septal incision extended into the left atrial roof.

Figure 4. Exposure of the mitral valve using sponge sticks.

The operation is continued in a standard fashion using conventional instruments. Repair techniques or valve replacement can be performed as usual. In certain cases (as in full sternotomy also) use of long shafted instruments can be helpful if manipulation of the subvalvular apparatus is required. Of course, left atrial ablation using cryo or radiofrequency energy can be achieved if required. After the mitral valve repair (MVR) or replacement, the interatrial septum and the roof of the LA are reconstructed using two layers of running 4-0 polypropylen suture. Procedures on the AoV and/or TV can be accomplished now. Surgery of the TV can be performed on the beating heart after releasing the aortic cross clamp (AoX) if regarded helpful. However, attention should be paid to the aortic root. The aortic root may well impinge onto the RA and make TV surgery on the beating heart very challenging. The RA is closed in a standard fashion. A subxyphoidal pericardial drain should be inserted before releasing the AoX to minimize the risk of laceration of the heart.

As the sinus node artery is divided in most cases bradycardia may occur and temporary dual chamber pacing leads are mandatory in patients with sinus rhythm (SR). Normal SR usually is reestablished within a few days. Weaning off CPB is completed and the operation finished. The sternum is fixed by conventional methods.

INDICATIONS

As mentioned above, indications for the UHS approach depend on patient and surgeon/center related factors:

- 1) If the surgeons feels uneasy with the video assisted or totally endoscopic lateral mini-thoracotomy approach for any reason or if there is simply no such equipment available, a UHS is a valuable alternative.
- 2) Patients with a (relative) contraindication for lateral thoracotomy like severe bullous emphysema, expected severe pleural adhesions or fibrosis may definitely benefit from a limited sternotomy approach. The same is true if retrograde perfusion through the femoral artery should be avoided in patients with severe aorto-iliac

atherosclerosis and when axillary artery or direct aortic cannulation is not desired (figure 5). Other conditions like pulmonary hypertension or restricted renal function are not regarded as a contraindication to video assisted MV surgery. Also concomitant ablation for atrial fibrillation (AF) or TV repair can be performed through the mini-thoracotomy approach. However, if AoV replacement has to be performed simultaneously upper partial sternotomy is ideal. Also coronary artery bypass grafting to the RCA is possible. Patients in SR bear a certain risk of postoperative rhythm disturbances so the indication for an extended transseptal approach should be considered seriously. If chronic AF is present, the choice of this approach is more obvious.

- 3) Contraindications: Patients who have had already cardiac surgery in the past are not ideal candidates for UHS redo surgery since isolation and encircling of the caval veins may be tricky. If very extensive annular calcium has to be resected and annular repair is planned, a full sternotomy will be the safer approach.

Figure 5. Calcified abdominal aorta.

SPECIAL CONSIDERATIONS

Choice of UHS length and shape: Using a J-incision into the 3rd ICS may do sufficiently, especially in women, however, the procedure can become really demanding and will need much more time. Even conversion to full sternotomy may become necessary. Therefore, the 4th ICS is the level of choice and we have not needed conversion due to inadequate access to and exposure of the MV. A softly curved 'J' shaped incision usually does fine and fracture of the sternal bone is no big issue. Although division of fibrous structures in the ICS close to the sternum is necessary, injury to the internal thoracic vessels is rare and division of these vessels usually is not required. The sternal incision is always carried to the left side since it gives better access to the MV and the left side of the sternum is elevated somewhat by the sternal retractor which gives even better exposure. As always in a UHS (also for AoV) before

institution of full CPB, emptying of the heart and deflation of the lungs, surgery of the MV virtually appears impossible. The contrary is true: due to the extended transseptal approach and dedicated exposure of the valve by the assistant, access is excellent and all procedures can be performed comfortably, except extensive resection of annular calcium and the following annulus reconstruction. Advantages of the UHS approach, of course, include the application of conventional techniques: no video, no screen, no long shafted instruments, no limited angulation of the instruments due to a very limited, few centimeters measuring hole in the thorax and finally no learning curve of a new surgical technique.

In our practice video assisted minimally invasive surgery is the technique of choice for MV repair and outnumbers the UHS cases by far. However, in certain situations, we are glad to have an alternative to full sternotomy and have not seen any disadvantages. Of course a limited approach makes surgery not easier but with dedication to surgical improvement and reduction of surgical trauma it can be achieved very well.

RESULTS

Since the introduction of UHS for MV surgery from May 2011 until June 2016, 71 (18.3 %) of 387 minimally invasive mitral valve procedures have been performed with this approach including 42 MVr and 29 MVR with additional 15 AoV replacements and 22 TV repairs. No mortality was observed and no conversions to full sternotomy were required. The high proportion of MV replacements (40.8%) reflects the underlying severe pathology of this patient cohort. No conversions to MV replacement for a failed repair was necessary.

CONCLUSION

UHS is a valuable minimally invasive approach for mitral and tricuspid valve surgery if contraindications for a lateral mini-thoracotomy with video assistance are present. Except a certain familiarity with limited access to the heart and a clear concept of the procedure, neither specialized training nor equipment are required. Definite indications for full sternotomy for isolated MV surgery have become rare.

Chapter 421

TOTALLY ENDOSCOPIC MITRAL VALVE SURGERY

Martin Misfeld*, MD, PhD and Friedrich W. Mohr

Heart Center, University of Leipzig,
Leipzig, Germany

ABSTRACT

Totally endoscopic mitral valve surgery (TE-MVS) represents a technique, which is part of the armamentarium of innovative minimally-invasive procedures. These procedures have gained increasing popularity over the last decade, not only due to the high patient demand and satisfaction, but also because of the proven safety and efficacy of this technique that is comparable to conventional procedures. It is associated with a lower risk of morbidity, improved patient comfort, shorter hospital stay and excellent cosmetic results. The totally endoscopic approach requires specific surgical skills, which involves the use of modified surgical instruments. In addition, establishment of extrathoracic cardio-pulmonary bypass and use of videoscopic guidance shifts direct vision of the heart, which the surgeon has during conventional mitral valve surgery through a standard median sternotomy to more indirect tools such as intra-operative transesophageal echocardiography. Standardization of the technique in TE-MVS increases the safety of this approach and results in excellent patient outcomes.

Keywords: minimally-invasive cardiac surgery, mitral valve surgery, endoscopic-surgery

INTRODUCTION

Mitral valve (MV) disease is the second most prevalent valve disorder in western countries [1]. Increasing lifespan of the general population is expected to escalate the number of patients with MV disease, which will further increase morbidity and mortality. In 2006, an age and sex-adjusted analysis reported a prevalence of 0.1% of mitral valve stenosis and 1.7% of mitral valve regurgitation (MR) in North America. It is estimated that the prevalence of

* Corresponding Author's Email: martinmisfeld@yahoo.com; Fax: +49 341 8651452c.

severe primary MR will increase up to 6.4% in the age group between 65 to 75 years and up to 9.3% in the age group older than 75 years [2]. MV surgery offers excellent results for various pathologies of the MV. The commonest surgical approach for MV surgery is still median sternotomy, as minimally-invasive techniques have not yet been adopted by the majority of cardiac surgeons so far. This chapter describes totally endoscopic mitral valve surgery (TE-MVS) in the context of minimally-invasive techniques. Following an overview of the history of MV surgery and the evolution of TE-MVS, the surgical techniques will be described in detail. Information on clinical outcomes of TE-MVS in comparison to conventional MV surgery through a median sternotomy will be followed by the description of potential pitfalls of this technique and the role of transesophageal echocardiography (TEE) in TE-MVS.

DEFINITION

‘Minimally-invasive cardiac surgery’ has been defined by the Society of Thoracic Surgeons (STS) database as ‘any procedure not performed with a full sternotomy and cardio-pulmonary bypass support’ [3]. As cardiopulmonary bypass (CPB) is mandatory for the performance of MV surgery today, minimally-invasive mitral valve surgery can be defined as any procedure performed without a full sternotomy as per this STS definition. Alternative surgical accesses and approaches are listed in Table 1.

Table 1. Surgical accesses and approaches in minimally-invasive mitral valve surgery

Partial sternotomy
transsternal incision
V incision
upper sternotomy
inverted T mini-sternotomy, J incision, L incision, inverted J incision, interved L incision
T mini-sternotomy, inverse L incision
Thoracotomy
right anterior mini-thoracotomy (forth to fifth intercostal space)
right parasternal incision
Video-assisted (endoscopic = videoscopic = thoracoscopic)
direct vision
via monitoring
2D, 3D
Robot-assisted
Da Vinci (Intuitive Surgical, Inc., Sunnyvale, California, USA)
Zeus (Computer Motion, Goleta, California, USA)
Telemanipulator (voice-activated) assistance
Aesop 3000 (Computer Motion, Goleta, California, USA)

HISTORY

Sir Lauder Brunton was probably the first physician to publish about the possibility of surgical treatment of MV stenosis in 1902. Following his experimental work, Elliot Carr Cutler performed the first successful MV operation in 1923. Together with the cardiology colleague Samuel Levine, a closed transventricular MV commissurotomy was performed on a 12-year-old patient with rheumatic MV stenosis at the Peter Bent Brigham Hospital [5]. Two years later, on May 6, Sir Henry Souttar was the first surgeon to dilate a stenotic MV by a digital manoeuvre through the left atrial appendage [6].

In the mid 1990s the success of laparoscopic operations in general surgery transferred this concept into the field of cardiac surgery. J. L. Navia and D.M. Cosgrove reported their results of minimally-invasive MV surgery through the right parasternal incision in 1996 [7], followed by L.H. Cohn, who performed MV surgery through the same access [8]. The first video-assisted mitral valve repair (MVR) through a mini-thoracotomy using ventricular fibrillation was described by Carpentier in 1996 [9]. Two years later, Carpentier also performed the first successful computer assisted MV surgery using the Da Vinci Surgical System [10].

Several important developments have facilitated TE-MVS. This includes peripheral CPB, endo-aortic clamping, introduction of retrograde cardioplegia catheter under echocardiographic guidance and the use of carbon dioxide (CO₂) in the operating field. In addition, developments of minimally-invasive valve surgery instruments, progress in perfusion technology and the importance of routine TEE participated to the growth of TE-MVS [11].

SPECIAL EQUIPMENT FOR TE-MVS

Various manufacturers have designed and developed instruments to meet the specific demands of TE-MVS. These instruments may also be used in conventional surgeries, when the lengths of standard instruments fall short in some patients. Soft tissue retractors, longer cannulae or catheters for cardioplegia delivery into the aortic root or the coronary sinus (retrograde cardioplegia) respectively are examples how developments in TE-MVS have improved patient safety and surgeon comfort. Advances in extrathoracic CPB with port-access systems, smaller and non-kinking arterial and venous cannulae and the routine use of CO₂ have further improved outcomes and safety of TE-MVS.

The introduction of 3-D systems into TE-MVS has enabled the surgeon to have a three-dimensional view of the operative field and a better perception of depth through the viewing monitor, resulting in enhanced tissue handling.

PATIENT SELECTION

Appropriate patient selection is a key factor for successful TE-MVS. In specific scenarios, TE-MVS can even be more beneficial than a complete sternotomy to reduce the

risk of operative complications. However, absolute and relative contraindications do exist for this technique (Table 2).

Table 2. Indications for TE-MVS

Absolute contraindications	Relative contraindications	Potential advantages of TE-MVS in specific co-morbidities
Significant untreated coronary artery disease	Obese patients	Reoperations following • Valve surgery • Coronary artery bypass surgery • without grafts to the right coronary artery previous • reconstructive surgery of an • infected sternum
Concomittant aortic or aortic valve pathology requiring surgical intervention	Reoperations	Obese patients
Prior right chest surgery	Mitral valve endocarditis	
Severe right lung adhesions	Pathologies of the descending aorta	
Aortic valve regurgitation > I°	Unsuitable femoral arteries to initiate CPB	
Severe mitral valve calcification or abscess formation requiring extensive mitral annulus remodeling		
Severe chest deformities with shifting of the heart to the left side		

Patients suitable for TE-MVS undergo isolated MV replacement or repair. Complexity of the underlying MV pathology should not be a contraindication for TE-MVS as all repair techniques can be performed through this approach. However, it is advisable that complex cases (i.e., Barlow's disease, combined mitral and tricuspid valve procedures) should be performed by experienced surgeons.

The following procedures can be performed in addition to MV surgery: tricuspid valve surgery, ablation therapy for atrial fibrillation, ligation/ closure of the left atrial appendage, PFO/ASD- closure and myectomy for hypertrophic obstructive cardiomyopathy.

SURGICAL TECHNIQUE

The most common surgical access in TE-MVS is a right lateral mini-thoracotomy. This technique will be described in detail. It is important to note, that a sternal saw be available at all times in case of an emergent conversion to a sternotomy approach.

Patient Preparation

The preparation of the patient for TE-MVS is the same as for a conventional MV operation performed through a sternotomy incision. However, due to the establishment of peripheral CPB, assessment of the femoral vessels is important. In cases in which port-access technology is used, further assessment of the descending aorta by computer tomography (CT) is routinely performed in some centers. It is also advisable to monitor the arterial pressure in both radial arteries to facilitate the proper position of the endo-balloon.

Depending on the surgical strategy, single or double lumen endo-tracheal tube can be are used. The latter enables preparation of the situs without early initiation of CPB and, therefore, helps reducing CPB time. If the ascending aorta is cannulated directly, a double lumen tube is mandatory. On the other hand, a single lumen tube and initiation CPB before thoracotomy, simplifies the procedure.

An example of an operation room set-up for TE-MVS is shown in Figure 1. Besides standard monitoring used during cardiac operations, additional monitors used for viewing images transmitted by the thoroscopes are positioned opposite the operating table for the surgeon and behind the surgeon for the assistant surgeon. The anesthetist, perfusionist and scrub nurse are also able to follow the steps of the procedure. Training of residents and medical students in MV repair and replacement is much superior with this set-up as compared to the limited view observers/assistants have of the MV through a median sternotomy during conventional MV procedures.

Figure 1. Operation room set-up for TE-MVS.

Patient Positioning

The patient is placed in a supine position with slight anterior-rotation of the right chest (30°). This can be achieved by placing a bolster under the right scapula of the patient,

enabling improved exposure for right mini-thoracotomy and adequate space for placement of the TE-MVS instruments and equipment.

It is advisable to mark out the desired location of the skin incision for the mini-thoracotomy and the sternal midline before application of the incise drapes, which should be used to further improve surgical field exposure, especially in women. Marking the submammary fold and pushing the breast cranially and to the left with the incise drape aids in achieving optimum cosmetic results. The marked sternal midline will also enable the surgeon perform a straight skin incision in rare cases in which the patient requires conversion to a sternotomy approach.

Initiation of Cardiopulmonary Bypass

Femoro-femoral CPB through the right groin is the commonest access site in patients undergoing TE-MVS (Figure 2). Therefore, coronary angiograms through the right groin should be avoided if performed immediately prior to surgery. Following a small, oblique skin incision (2–3 cm), the femoral vessels are dissected free of the surrounding tissues. Following heparinisation, a purse-string or pledgeted 4.0 monofilament U-stitch is passed through the anterior wall of each vessel. It is often easier to insert the venous cannula first, due to the anatomical position of the vessels. The guide wire is passed through the right femoral vein into the right atrium and superior vena cava (SVC) under TEE guidance using the Seldinger's technique. Following pre-dilatation of the opening in the femoral vein, the venous cannula is also passed cranially through the femoral vein so that its tip lies in the superior vena cava. Thereafter, femoral artery cannulation is similarly performed. In single lung ventilation, CPB is initiated at this stage in patients with a single-lumen endotracheal tube. In patients with a double lumen endotracheal tube, CPB can be initiated after opening the pericardium.

Vacuum suction will improve venous drainage. An additional jugular venous cannula can be inserted into the SVC under TEE guidance in obese patients or in those requiring additional right atrial interventions, either in the induction room after induction of anesthesia or in the operating room after prepping and draping the patients. As a bailout maneuver in patients with insufficient venous drainage via femoral cannulation, direct cannulation of the SVC through the mini-thoracotomy or a separate incision may be an option.

Figure 2. Femoro-femoral cardiopulmonary bypass for TE-MVS.

Operations are performed under mild hypothermia. Crystalloid or blood cardioplegia can be used. However, repeated delivery of blood cardioplegia interferes with the surgical set-up and work flow, thereby prolonging aortic cross-clamp (AoX) and CPB time.

MV reoperations can be performed under mild-moderate hypothermia (30°C) and ventricular fibrillation without aortic clamping, thus avoiding dissection of the ascending aorta. A competent aortic valve and preserved left ventricular function are the prerequisites for safe execution of this technique.

Mini-Thoracotomy

The skin incision should be made to facilitate the best cosmetic results after the operation. This is particularly important in women. An antero-lateral small thoracotomy is performed, following skin incision and dissection of the subcutaneous tissue. The 4th intercostal space (ICS) is the commonest entry site into the chest. Some surgeons use the areolar margin to enter the chest for cosmetic reasons. If additional right atrial procedures have to be performed, the incision should be slightly more anterior compared to an incision for isolated MV surgery.

It is advisable, at first, to make a small opening (finger's breadth) in the ICS and palpate the diaphragm through it with a finger. The distance of the diaphragm from the opening gives the surgeon a very good idea of whether the ICS is appropriate for entry into the thorax. Once the desired site of entry is confirmed the appropriate ICS is widely opened. The use of a soft tissue retractor provides adequate space through which the surgeon can work comfortably. The endoscope is inserted through a 5 to 10 mm portone intercostal space superior to the mini-thoracotomy. A small incision (3-4 mm) medial to the thoracotomy can be used to exteriorise the cardioplegia cannula and insert the left atrial retractor.

The pericardium is opened parallel and preferably 3-4 cm anterior to the phrenic nerve to avoid too much traction on the latter in case of using pericardial stay sutures. If necessary, excessive pericardial fat pads should be excised for better visualization. Additional retraction sutures may be used to pull the diaphragm inferiorly. These sutures can be brought out directly through the lateral edge of the skin incision. Cardioplegia can be delivered either through a metallic needle or a standard long plastic cannula inserted into the aortic root or through a retrograde cardioplegia cannula inserted under TEE guidance.

An additional retraction suture is placed in the interatrial groove at the level of the right superior pulmonary vein and is brought out of the thorax through the same incision through which the cardioplegia cannula is exteriorized. Gentle traction on this suture facilitates the opening and closure of the left atrium.

The aorta can be clamped with a transthoracic clamp, which is inserted posteroinferior to the thoracoscope. Interference between both instruments should be avoided. Another option is the use of an endo-balloon, the placement and position of which is facilitated by TEE. CO₂ can be insufflated of 3-5 L/min into the thorax via the cannula through which the endoscope is inserted or via an additional tube.

An example of the access to the chest and positioning of additional TE-MVS equipment is depicted in Figure 3.

1. mini-thoracotomy, 2. incision for left atrial retractor, 3. position of thoroscopes, 4. insertion of X-clamp, 5. access to the femoral vessels for CPB

Figure 3. Example of the access to the chest and positioning of equipment for TE-MVS.

Following aortic clamping and delivery of cardioplegia, left atrium is open and the MV is exposed and assessed. Appropriate techniques for MVr such as neochordal replacement or resection techniques are performed according to the type of valve pathology, when the valve is deemed repairable. If not repairable, MV replacement can be performed in standard fashion. The left atrium is closed in 2 layers following repair or replacement of the MV. The pacemaker wire inserted preferably before removal of the AoX. The heart is then deaired and the AoX is removed. The patient is then weaned from CPB to assess the MVr or replacement on TEE. Once the findings are as desired, CPB is resumed so that the cardioplegia cannula can be removed. The needle vent site should be securely oversewn with a pledgeted monofilament suture. Hemostasis is confirmed. The pericardium may be closed before or after weaning from CPB. One or two drains are inserted according to surgeon's preference. The femoral vessels are decannulated followed by protamine. The chest and groin wounds are then closed in layers.

CLINICAL OUTCOMES

In 2014, 47.3% of the 5913 isolated MV procedures were performed with the minimally-invasive approach in Germany [12]. Data is still limited. However, systematic reviews have shown, that minimally invasive MV surgery is safe and effective and shows no differences in outcomes when compared to conventional MV surgery via median sternotomy [13-15]. Although the minimally-invasive approach and especially TE-MVS requires longer CPB and AoX times, this technique has shown to have significant advantages with regard to decreased postoperative pain, reduced surgical trauma, better respiratory function, fewer transfusions, and, therefore, greater patient satisfaction [16-18].

The quality of valve surgery, especially repair has been at par with standard MV surgery. Depending on the complexity of MVr, repair rates greater the 90% can be achieved in experienced centers [16, 19-22]. TE-MVS is associated with low morbidity and mortality similar to the conventional approach. Long-term survival and freedom from valve-related complications and reoperations are also comparable to standard MV surgery.

Table 3. Concepts of TE-MVS

Endoscopy	Initiation of CPB	Cardioplegia	Aortic clamping	Varia
5 or 10mm camera system with various camera angles	Femoral vein with/without additional jugular vein cannulation	Cristalloid or blood cardioplegia	External clamping (transthoracic, endothoracic)	CO ₂ -application into the operative field
2D-videoscope	Femoral artery	Administration via aortic root	Port Access technology with endo-aortic clamp	Bi-radial artery line when endo-aortic clamp system is used
3D-videoscope	Ascending aorta	Retrograde cardioplegia (TEE guided insertion)		Single or double lumen ventilation
Computer guided videoscope (AESOP 3000, voice controlled robotic arm)	Axillary artery	Cardioplegia administered via endo-aortic clamp system		Soft tissue retractor with/without metal retractor

Even procedures requiring complex MVR, (i.e., Barlow's mitral valve disease), can be performed with TE-MVS [23]. With the introduction of simplified techniques such as the 'Leipzig Loop Technique', complex MVr has been made feasible with this approach [20].

It has been demonstrated that TE-MVS may be advantageous and lead to better outcomes especially in higher risk patients. This is true for selected cases of reoperations and elderly patients [24, 25].

POTENTIAL PITFALLS

TE-MVS has become the standard technique for MV surgery in some centers. There is still a lack of adopting this approach in other institutions. Reports published so far represent high volume centers with a broad experience with this technique. It has been shown that TE-MVS requires a learning curve, which varies between individual surgeons [26]. Awareness of potential pitfalls and avoidance of complications helps to increase the adoption of TE-MVS in more centers.

Potential pitfalls include improper patient selection and preparation, mistakes during establishment of CPB, insufficient patient set-up and complications associated with MV surgery per se. A list of potential pitfalls, their detection and avoidance are listed in Table 4.

Table 4. Potential pitfalls, complications and how to avoid them

Potential pitfalls	Possible complications	Potential solutions
Improper patient selection	Too complex mitral valve pathology or reoperation Right chest adhesions Thorax deformations Severe obese patients Severe calcification or abscess formation of the mitral valve annulus	Every mitral valve pathology can be repair with TE-MVS. Depending on the surgeons expertise, pathology may be too complex or reoperation may be too challenging for the minimally approach See also relative/absolute contraindications (table 2)
Inadequate patient preparation	Insufficient patient positioning Bad cosmetic result	Adequate elevation of the right chest and positioning of the right arm to ensure enough space for the set-up of TE-MVS Mark skin incision line and use foil for proper retraction of the breast, especially in women In obese patients (especially women) pushing the breast downwards and performing a thoracotomy anterior to the breast may be an alternative
Wrong establishing of CPB	Complications of arterial/venous vessels during cannulation (e.g., aortic dissections, retroperitoneal hematoma, local dissections of femoral artery) Insufficient venous drainage	Control of adequate guiding wire position by TEE in the vena cava superior during venous cannulation and in the descending aorta during aortic cannulation Avoid oversizing of arterial cannula Use of vacuum suction, additional venous neck cannula in obese patients

Potential pitfalls	Possible complications	Potential solutions
	Aortic dissection during X-clamping Malpositioning of endo-clamp Complications from cardioplegia line	If necessary insert an additional venous line through the TE-MVS access Stop CBP during application and release of X-clamp TEE control of adequate endo-balloon positioning and bilateral arterial pressure control Apply an additional reinforced suture, applied with X-clamp is still on or under short run of low flow perfusion Avoid TE-MVS access in patient with aortic valve regurgitation > 1°
Insufficient set-up	Improper administration of cardioplegia via the aortic root Wrong intercostal space entered Elevated right diaphragm interfering with access to the pericardium Damage of phrenic nerve Damage of internal mammary artery by left atrial retractor	Check chest X-ray for position of right diaphragm Enter chest with left index finger first an check for position of diaphragm “Enter the chest in women always one intercostal space higher than you think” retraction suture placed in the center of the diaphragm (pledged reinforced or pure-string suture, should be knotted to avoid bleeding), beware of liver damage incise pericardium at least 2 cm above the phrenic nerve check with thoracoscope for position of IMA before entering the chest Change angle/access of intercostal space for thoracoscope Avoid interference with thoracoscope and change position if necessary

Table 4. (Continued)

Potential pitfalls	Possible complications	Potential solutions
	Wrong position of thoracoscope	
	Wrong position of X-clamp	Retract left atrial appendage (LAA) to avoid damage by the X-clamp If the LAA is damaged, repair may be performed with the X-clamp still on through the transverse sinus. Use of special external closure devices for the LAA may be helpful
Complications associated with mitral valve surgery	Improper presentation of the mitral valve by left atrial retractor	Special devices are available to push the inferior part of the left atrium downwards Place annuloplasty suture in the posterior part for improved mitral valve exposure
	Damage of circumflex artery	Use temporary retraction sutures on mitral valve leaflet or insert sizer for mitral valve replacement placed in the annulus to explore subvalvular apparatus
	Damage of conduction system	Still on CPB: Check circumflex artery for flow before and after mitral valve surgery by TEE, check for wall motion abnormalities with TEE after mitral valve surgery
	Damage of aortic valve or aortic root	Place pace maker wire with X-clamp still on Check for aortic valve competence and exclude aortic root hematoma with TEE

Potential pitfalls	Possible complications	Potential solutions
Varia	Re-expansion pulmonary edema	<i>Remark: Mechanism is unclear. Long CPB time, pulmonary hypertension, use of fresh frozen plasma, diabetes and chronic obstructive lung disease may be risk factors</i>
	Air embolism	Steroids may be used De-air via a separate line connected to a three-way cock of the cardioplegia root line. Change position of the table during de-airing maneuvers of the heart with the X-clamp still on Use Carbon dioxide insufflation into the chest with a flow of 3 L/min. Inspect every stab wound for hemostasis with thoracoscope, before chest is closed
	Bleeding from the chest wall	

LEARNING TE-MVS

To overcome the learning curve of TE-MVS, it is advisable to become aware of the potential pitfalls of this technique. The minimally invasive instruments should be used in the wet-lab to gain familiarity. They may also be beneficial in certain cases of median sternotomy, when standard instruments fall short due to inadequate length.

Practicing in a wet-lab on cadavers and attending wet-lab courses should be followed by visiting experienced centers in TE-MVS. It is also advisable to have a proctor while performing the first few cases. It is important to carefully select the first patients. Simple MV pathologies, ASD-closure, left atrial ablation procedures or left atrial myxomas may be cases to be chosen in the initial phase.

ROLE OF TRANSESOPHAGEAL ECHOCARDIOGRAPHY IN TE-MVS

TEE plays an important role in TE-MVS. It is mandatory for the evaluation of MV pathology and to assess the final operative result. In addition, verification of appropriate position of guide wires during venous and arterial cannulation and detection and exclusion of potential pitfalls should be routinely performed. This includes demonstration of the circumflex artery and its flow, evaluation of biventricular contractility, assessment of the aortic valve function, especially for its competency and the aorta and aortic root (see also table 4).

Adequate deairing should be performed under TEE control. Weaning from CPB and volume management in the initial phase after coming off pump is dependent on TEE, as cardiac filling cannot be judged by direct vision.

CONCLUSION

TE-MVS has grown significantly over the last decade. It has been shown to be equivalent to conventional MV surgery through a median sternotomy, whilst reducing ventilation and hospitalization time, decreasing blood loss and postoperative pain. The cosmetic results are excellent. This is why TE-MVS is frequently demanded by patients.

As specific surgical skills and the use of modified instruments and surgical equipment is necessary to perform TE-MVS, a learning curve still exists. To shorten the learning curve and to decrease the risk, surgeons should be aware of potential pitfalls associated with this procedure. It is hoped that with increasing expertise in a larger surgical community, TE-MVS will become the standard of care for MV surgery in selected patients within the next few years.

Chapter 422

ROBOTIC ASSISTED MITRAL VALVE SURGERY

***Arman Arghami, Richard C. Daly*, Simon Maltais
and Joseph A. Dearani***

Cardiovascular Surgery Department of Mayo Clinic,
Rochester, MN, US

ABSTRACT

Robotic mitral valve (MV) repair is now routinely and safely performed for complete anatomic correction of all categories of MV leaflet prolapse, regardless of complexity. Robotic repair can be undertaken with or without concomitant tricuspid valve repair and atrial fibrillation ablation procedures, or even mitral valve replacement. The approach can be used to excise benign tumors from the mitral valve or left atrium. Compared with conventional sternotomy, this procedure offers patients the advantages of reduced blood loss, lower risk of incisional infection and atrial fibrillation, shorter hospital length of stay, quicker return to normal activities, and a superior cosmetic result. Midterm quality outcomes after robotic MV repair are excellent, and thus the procedure may be particularly appealing in asymptomatic patients with preserved LV function undergoing correction of severe MR according to ACC/AHA class IIa Guideline recommendations to optimize long-term survival and decrease late heart failure risk.

Keywords: robotic surgery, minimally invasive, mitral valve, mitral regurgitation, mitral valve prolapse

INTRODUCTION AND HISTORY

Although it was one of the first intracardiac procedures to be performed (valvotomy in 1925), mitral valve (MV) surgery has evolved significantly in the last century. Since the invent of cardiopulmonary bypass (CPB) in the 1950s, MV procedures have been done routinely through median sternotomy. In 1995, surgeons started focusing on benefits of

* Corresponding Author's Email: rdaly@mayo.edu.

smaller sternal incisions and short CPB time. Soon thereafter mini-thoracotomy and video assisted minimally invasive operations were introduced. Special instruments were made to assist with the newly emerging field including the transthoracic aortic cross clamp (AoX) [1].

Robot-assisted MV repair (MVr) was introduced in the late 1990s with the goal of improving the technical precision of less-invasive surgical MV reconstruction. In 1998, Carpentier [2] in France and Mohr [3] in Germany serially performed the first cardiac surgical procedures using the da Vinci Surgical System (Intuitive Surgical, Inc, Sunnyvale, Calif). Later, Lange's group in Munich [4] performed the first closed chest endoscopic MVr. In May 2000, under the first Food and Drug Administration (FDA) robotic investigational device protocol (G000023), Dr. Chitwood and Dr. Nifong and colleagues performed the first Robotic Assisted repair of MV using the da Vinci surgical system in the United States [1]. Their team then completed the the first FDA trial involving 20 patients to investigate the safety and efficacy of robotic MV procedures [1]. Ever since the utilization of this new technique has been increasing. Among 8814 MVr procedures reported to the Society of Thoracic Surgeon Database in 2013, 1132 (12.84%) were performed using robotic assistance [1, 5].

Recently, new information supporting the advantages of prompt surgical correction of primary severe mitral regurgitation (MR) to both prevent excess long-term mortality and diminish heart failure risks [6, 7] has led to a further evolution in thinking regarding the ideal timing for MVr. Further, MVr is now reproducible with approximately 99% certainty; it is effective, durable, and safe with very low risks of postoperative mortality and morbidity, particularly in high-volume centers [8, 9]. This has placed pressure on procedures providing better cosmetic results and pain and discomfort, and shortened hospital stay and recuperation, while maintaining benefits and results of a more traditional open approach.

There are several potential advantages of robotic MVr versus standard thoracoscopic approaches. First, enhanced surgical dexterity is allowed, facilitating precise movements of instruments in the closed chest and avoiding the fulcrum effect characteristic of long shafted endoscopic instruments experienced during minimally invasive procedures. Second, high-definition 3-dimensional visualization places the surgeon inside the left atrium with the line of vision parallel to the flow of blood into the valve. Visualization of the subvalvular apparatus is superior to that obtained using other approaches, so that any type of myxomatous pathology including fibroelastic deficiency and Barlow's disease can be treated with the standard techniques of triangular resection, insertion of artificial chordae, edge-to-edge repair or commissural plication. Third, the cosmetic results are appreciated by both female and male patients, particularly in patients with prior breast reconstruction. Because of the reduced surgical trauma and avoidance of the median sternotomy, the requirement of heterologous blood products (7%) and the incidence of atrial fibrillation (AF) (odds ratio, 0.79) and postoperative pain have been reported to be lower in minimally invasive mitral procedures [5, 10, 11].

In this chapter we review (1) indication and contraindication for robotic MVr, (2) the surgical technique, and (3) describe the early postoperative and long-term outcomes and advantages of this technology.

EVALUATION

Workup

All patients undergo an ECG gated computed tomography (CT) angiography of the chest, abdomen and pelvis. This screens out significant coronary artery disease and also allows the surgeon to determine the left or right dominance coronary system which would be of great importance in regards to suturing around the mitral annulus. The CT angiogram also screens for and assesses the extent of aortoiliac atherosclerosis for peripheral cannulation. These findings along with cardiac multidetector CT looking for MV annular calcification could potentially change the recommended surgical approach from minimally invasive robotic surgery to standard sternotomy-based surgery [12]. The CT scan is also helpful in patients with sternal or thoracic deformities to help determine whether robotic instrument trajectories will be compromised. Patients with significant risk factors for carotid/peripheral vascular disease should be screened by CT/ultrasound/Magnetic Resonance Imaging (MRI). If there is any concern about significant coronary artery disease on the CT scan, formal coronary angiography is performed. A right heart catheterization may be indicated in patients who have significant pulmonary hypertension, especially with depressed right ventricular (RV) function. An excellent transthoracic echocardiography or transesophageal echocardiography (TEE) study should be performed to evaluate valve anatomy, pathology, suitability for repair, left ventricular (LV) function, ascending aortic size, aortic valve disease and competency, tricuspid valve (TV) competence and presence of patent foramen ovale. A TEE would be necessary if there are questions regarding the mechanism of mitral insufficiency and ability to repair. In the operating room, TEE to delineate MV anatomy and pathology as well as postoperative evaluation of the repair is essential [5].

Indications

As for many other surgical procedures, robotic MVR was initially reserved for a very selective group of patients. The selection criteria has widened as surgeons have refined the techniques and gained confidence. Robotic MVR is appropriate for both degenerative and functional MV disease. Furthermore, MV replacement, concomitant Cox-Maze IV procedures using cryoablation, TV repair and tumor resection (papillary fibroelastoma) all have been reported and can be performed with relative ease [5, 13-15].

Although we won't discuss the indications for MVR in this chapter, it's worth noting that there is a recent interest in early referral for MVR. Large series have shown excellent late outcomes of MVR using standardized surgical techniques [7, 8] along with reduction annuloplasty support [16, 17]. There may be a few contraindications to performing robotic assisted MV surgery. Patient selection involves assessment of operative risks and mitral anatomy/pathology. Minimally invasive approaches, including robot assisted approaches, inherently involve less access to the heart. Factors such as significant aortic insufficiency, LV dilatation, reduced LV and/or RV function may increase the risk for LV distension or difficulty with cardioversion and may have a more profound impact on risk than these conditions would have in an open procedure.

It should be kept in mind that the goal of patient evaluation and selection, as well as preparation for and conduct of the operation should all be done with the intention to keep surgical risk as low as it is for a standard open procedure. Attention to detail throughout the process is critical.

The contraindications for robotic MV surgery can be broken down into four categories; (1) Difficulty with access through the right chest: this can include previous right thoracotomy, poor lung function with intolerance to single lung ventilation, chest wall deformity and body habitus including severe obesity (2) Need for concomitant operation: such as CABG or other valve surgeries excluding TV repair (3) Difficulties with cannulation or retrograde aortic perfusion: significant aortoiliac atherosclerotic disease. The cannulation site of the proximal ascending aorta for cardioplegia and venting is more risky and can be more difficult to repair if there is significant aortic root/ascending aortic dilation (4) General contraindication for MVr.

Table 1. Contraindications to robotic mitral valve repair

Right chest access	Contraindication
Previous right thoracotomy	Strong
Severe pulmonary dysfunction	Strong
Moderate pulmonary dysfunction	Relative
Chest wall deformity and body habitus	Relative
Previous sternotomy	Relative
Need for concomitant operation	
Coronary artery bypass	Strong
Severe aortic valve insufficiency	Strong
Mild to moderate aortic valve insufficiency	Relative
Additional heart valve disease	Relative
Cannulation	
Sever peripheral arterial disease	Strong
Limited peripheral vascular disease	Relative
Significant aortic root/ascending aortic dilation	Strong
Calcification of aortic root/ascending aorta	Strong
MV repair	
Mitral annular calcification	Strong
General	
Myocardial infarction or ischemia < 30d	Strong
Symptomatic cerebrovascular disease or stroke < 30d	Strong
Right ventricular dysfunction	Strong
Pulmonary hypertention (fixed >60 torr)	Strong
Severe liver or renal dysfunction	Strong
Significant bleeding disorder	Strong
Asymptomatic cerebrovascular disease	Relative
Poor LV function (EF<50%)	Relative
Pulmonary hypertention (variable >50 mmHg)	Relative

TECHNIQUE

Although a few variations exist in robotic MV surgery technique, such as totally endoscopic technique, herein we describe the robotic technique that is used in our institution.

Patient Positioning

The patient is placed in a supine position with a roll under the right scapula, elevating the right chest to approximately 30-45 degrees above the horizontal plane in order to achieve optimal exposure of the right anterolateral hemithorax for direct access to the MV. The right arm is allowed to drape posteriorly and secured at a level below the posterior axillary line to allow the shoulder to fall back and expose the right axilla [18] (Figure 1).

Figure 1. Patient positioning: A roll is placed under the right shoulder and right arm is allowed to drape posteriorly and secured at a level below the posterior axillary line to allow the shoulder to fall back and expose the right axilla.

Port Placement

With single left lung ventilation the right lung is deflated and right thoracic access ports are fashioned. A 2-3 cm working port is created lateral to the right nipple in the fourth intercostal space (ICS) (Figure 2 and 3). A camera port is placed between the working port and the nipple areaola in the same (fourth) ICS. Alternatively, the working port can be extended anteriorly a short distance and the camera placed through the working port. If the right hemidiaphragm is interfering with the exposure, a pledgeted 2-0 silk suture is passed through the central fibrous portion of the diaphragm medial and posterior to the dome of the diaphragm and exteriorized using a laparoscopic suture passer, through the right chest anteriorly about the 6th ICS under tension.

Figure 2. Schematic drawing of the port placement and their relation to the chest wall.

Figure 3. Working port placement, lateral to the nipple (rib numbers have been marked).

Figure 4. Intraoperative photo with all ports in place prior to docking of the robot. Note the location of the diaphragm (anterior) and pericardial (posterior) retraction sutures.

The pericardium is opened longitudinally under direct vision 4 cm anterior to the phrenic nerve and its posterior edge is suspended on stay sutures, which are exteriorized through the fourth ICS posterior to the working port. A site is selected in the right third ICS lateral to the right internal thoracic vessels to allow direct trajectory of a long cardioplegia/vent catheter to the ascending aorta. A grasper is passed through this site and a long vent catheter (Medtronic, Minneapolis, MN, USA) is pulled through the chest wall. The catheter is then flushed in a retrograde manner to clear fat or soft tissue debris. We also employ a cap over the cannula to further minimize chances of fat and debris getting into the tubing. The position of this catheter is important. The ideal location should allow for a perpendicular position to the desired aortic vent site. A common mistake is to have the cannula come in from further cephalad which may direct the cannula insertion needle toward the aortic valve. This is a concern because the cardioplegia/vent cannula is placed low on the ascending aorta because the cephalad space for placing the AoX is limited by the right pulmonary artery in the transverse sinus. The snare for the cardioplegia/vent catheter is brought out through the working port. With direct palpation through the working port, a 0.8-cm port for the left robotic arm is placed two interspaces above the working port and about 3 cm anterior to the anterior axillary line. Another 0.8-cm port for the right robotic arm is placed two interspaces below the working port (6th intercostal space) at the anterior axillary line. The left atrial retractor port is placed about 4 cm medially to the camera port in the fourth interspace, in a manner that avoids injury to the internal mammary artery/vein, usually in the inframammary crease. The Alexis soft tissue retractor (AppliedMedical, Rancho Santa Margarita, CA) (size XX-Small, 1–3 cm) is then positioned inside the working port (Figure 4). This facilitates repetitive movements of instruments into and out of chest also prevents tissue debris from entering the heart [18].

Cannulation, Cardiopulmonary Bypass and Myocardial Protection

The right common femoral vessels are exposed through a 1- to 2-cm oblique incision 2 cm cranial and parallel to the inguinal crease. The incision should not extend lateral to the femoral artery to avoid injury to the superficial cutaneous nerve which can affect sensation in the medial thigh territory. Two purse-string sutures are placed in the right common femoral artery and a single purse-string in the right common femoral vein.

A 22-F or 25-F multistage venous cannula is inserted using the Seldinger technique with echocardiographic guidance and advanced 4 cm superior to the junction between the superior vena cava (SVC) and right atrium. Another 16-F or 18-F cannula is percutaneously exchanged over a wire inserted through the previously placed 8.5-F right internal jugular sheath into the SVC. TEE is used to confirm the final position and ensure the absence of overlap between the two venous cannulae. A 17- or 19-F femoral arterial cannula is placed via the right common femoral artery. Echocardiographic guidance assures position of the arterial guidewire in the descending aorta before full femoral artery cannulation. Once the activated clotting time is adequate and the robot is docked (Figure 5), CPB is initiated while monitoring the descending thoracic aorta by TEE to confirm normal flow and the absence of a dissection flap. Patient temperature is allowed to drift to 34°C. With the right atrium empty, the pericardiotomy is extended cranially over the ascending aorta. A 3-0 polypropylene purse-

string suture with a felt pledget is placed in the ascending aorta. The previously placed cardioplegia tack vent is inserted through the purse-string and snared into place.

Figure 5. Intraoperative photo with robotic arms docked in place.

The transthoracic AoX is inserted through a small stab wound in the right axilla. A superior and posterior position of the cross clamp will help to avoid conflict with the left robotic arm. The AoX is positioned through the transverse sinus, taking care to avoid injury of the right pulmonary artery and left atrial appendage. The heart is arrested with 1 liter of cold blood high potassium cardioplegia, which is repeated every 20 min throughout the AoX time. Recently, we have used a single dose of del Nido cardioplegia solution.

The left atriotomy is carried out at the interatrial groove allowing a sufficient cuff on the anterior surface of the right pulmonary veins to permit closure. The oblique sinus is opened posterior to the inferior vena cava to reduce blood pooling and help with exposure. The robotic left atrial retractor is positioned and the MV is analysed [18].

Leaflet Repair and Annuloplasty Band

Our philosophy is that the highest quality MVr techniques with proven durability should not be altered to facilitate performance of the operation through small incisions. We therefore employ exactly the same standard techniques of MVr regardless of the surgical approach as previously published [19, 20]. For posterior leaflet disease, we typically perform standard triangular resection with two-layer running polypropylene reconstruction. For anterior leaflet prolapse, we use artificial chords with polytetrafluoroethylene (Gore-Tex; W.L. Gore & Associates, Inc., Flagstaff, AZ, USA). Patients with bileaflet prolapse undergo prolapse correction utilizing a combination of these techniques. Repair adjuncts include commissural or leaflet plication, leaflet shortening/ ventricularisation and posterior leaflet neochord placement - all of which are employed as indicated. All repairs are supported with a standard length 63 mm posterior annuloplasty band inserted in the standard manner with 2.0 Ethibond or Prolene interrupted sutures, anchored at the left and right fibrous trigones, that are tied by the bedside surgeon. Once the repair is tested with saline insufflation and found to be perfect, the left atrium is closed with running 3.0 prolene sutures starting at both ends of the left atriotomy and the sutures are tied in the middle. After deairing of the left heart, the AoX is removed. The patient is separated from CPB and TEE is performed to assess the adequacy of the repair and atrial suture line is inspected for hemostasis. CPB is temporarily resumed for safe removal of the cardioplegia/vent tack, tying of the stitch and placement of a reinforcing stitch. Decannulation and reversal of heparin are then performed following which, meticulous haemostasis is ensured. A 19-F soft silicone (Blake; Ethicon) pericardial drain inserted through the oblique sinus after which the pericardium is closed, and a 32-F right pleural chest tube is positioned in the posterior thorax and secured in place. Incisions are closed in the standard manner [18].

OUTCOMES

Recent data point to increasing number of MV procedures being done by minimally invasive and robotic techniques. In a recent report amongst 8,814 MVr operations in USA, 1,132 (12.84%) were done using robotic assistance in 2013; similar to a previously reported trend [21, 22]. There is an abundance of published literature on outcomes of robotic MV surgery. Although a randomized clinical trial is missing, the outcomes are undeniable.

In 2015, outcomes were published from our institution of 487 robotic MV procedures. We reported a 99.5% 5 year survival, 94.6% 5 year freedom from MR and 97.7% freedom from reoperation at 5 years. The stroke risk was 0.8%. The complexity of technical repair did not appear to influence MR recurrence or MV reoperation risk [17]. In 2015, Murphy and colleagues [23], reported their experience with 1257 robotic mitral valve procedures. Their operative mortality was 0.9% and at a mean of 50 months followup, overall survival was 97.2%, and stroke risk of 0.7%. In their series 3.9% required reoperation. They commented that with increasing experience, the reoperation rate dropped to 0.9% in the second half of the study period with mean followup of 29 months. More than half of the recurrence and reoperations were due to prolapse or ring dehiscence. The latter decreased after abandoning the nitinol clips.

In earlier studies as in the report by Chittwood and colleagues in 2008 of 300 consecutive robotic MV operations, outcomes reported were 30-day mortality of 0.7%, 5 year survival of 96.6% and 93.8% freedom from reoperation at 5 years. Stroke risk was 0.7% and transient ischemic attack of 1%. Myocardial infarction (MI) occurred in 2.3% [24]. In 2014 Ramsey and colleagues [25] reported on their 300 consecutive robotic MV procedures. Thirty day mortality was 0.3%, risk of stroke 1.7%, reversible neurologic injury 0.7%, and MI occurred in 0.3%. All of their results improve in the second half of their cohort as the operative experience increased [25].

Several studies have demonstrated that although initial AoX, CPB and total operative times were longer as programs began, there were no differences between groups undergoing robotic versus non robotic MVr as the program gained experience [8]. The overall median AoX time of 53-82 minutes, and perfusion time was 76-114 minutes. Ramsey and colleagues demonstrated that implementing a vigorous regimented stepwise approach of training new surgeons, resulted in shortened learning curve with added benefit of preventing complications that are seen with novice surgeons. Their results reduced operating time by 25% and CPB time by 40% compared to first case of each surgeon [25].

Other than the discussed complications, there are few other less common complications, some specifically related to robotic MV operations. These include CPB access complications such as iliofemoral artery dissection, aortic dissection, groin hematoma, infection or nerve damage during dissection. Each of these complications has been reported in less than 1% in the reported literature [23, 26]. MI with involvement of the circumflex artery especially in left coronary dominant system patient has been reported 0-3% [8]. Another unique complication reported in some series is unilateral pulmonary edema up to 1.4%. Moss and colleague suggested a modification to patient positioning and perfusion and ventilation and have significantly limited this complication [27].

Comparison with Open Mitral Repair

Recent landmark open MVr outcomes published by David et al. [28] detailed long-term outcomes of 840 patients undergoing MVr for MR attributable to degenerative disease with 10.4-year median follow-up. Freedom from recurrent moderate or severe MR at 20 years was 69.2%. The risk of mitral reoperation was 5.9%. As mentioned before, robotic outcomes at least until 5 years followup in recent publications are similar [17]. In 2011, Mihaljevic et al. [29], in their series of 759 patient with MV procedures, compared robotic MVr to sternotomy, mini sternotomy and mini thoracotomy. Their repair results were similar between the groups and overall complication rates were also similar. CPB time was longer (42 min longer) for robotic compared to sternotomy, and AoX time was 26 minutes longer. The complication rate was mostly the same. Robotic MV surgery patients had the lowest incidence of AF and had shorter hospital stay. They concluded that longer procedure time is compensated by less invasive approach and shorter hospital stay [29].

Besides obvious cosmetic benefit and perhaps less discomfort, robotic MVr has been shown to be associated with a shorter hospital length of stay (3-4 days) and quicker return to work and perhaps improved quality of life [8, 10, 17, 23].

LIMITATIONS AND RISKS

Surgery using robotic instruments has 2 notable limitations. First, the robotic surgeon has no sense of proprioception. Robotic surgeons must be highly disciplined to avoid moving a robotic instrument unless it is in the endoscopic visual field to avoid inadvertent injuries to intra-thoracic structures with unwanted movements of robotic arms especially outside of the visual field. Newer model robotic systems have visual aids to allow the surgeon to locate instruments outside the endoscopic field without invoking the help of the patient-side assistant. Second, the robotic instruments have no tactile feedback. In practice, this has not been a practical limitation. Robotic surgeons also develop an “ocular tactility” as they learn to use visual cues to guide their tissue handling, similar to that used by professors in the training of younger surgeons [5]. Limitations related to minimal incisions and reduced cardiac access have been discussed above.

Reduced tactile feedback is especially important during annular suturing and avoidance of circumflex artery injury or kinking which have been reported. So special attention should be made to ECG changes post-op and cardiac catheter should be performed immediately if there is any hint of coronary artery injury. Kinking and not a complete blockage is common and this is usually amenable to stenting. As is always the subject of debate, robotic surgery has some upfront expenses but studies have shown that by reduction of ICU stay and hospital stay and efficiency of the high volume centers, robotic surgery has reduced the cost to similar levels of open operations (\$30,606 vs \$31,310). In addition these patients return to work sooner which results in overall better economic sense [5, 9, 30].

Chapter 423

REDO MINIMALLY INVASIVE MITRAL VALVE SURGERY

Marco Solinas, MD and Michele Murzi*, PhD

Adult Cardiac Surgery Department,
Fondazione Toscana Gabriele Monasterio,
Massa, Italy

ABSTRACT

In recent years, less invasive procedures have emerged as the new trend in mitral valve surgery. The conviction that minimally invasive mitral valve surgery (MIMVS) could be performed with similar hospital mortality versus standard approach, but with less blood transfusion, earlier recovery of daily activities and with higher patient satisfaction, have driven its diffusion in most centers worldwide. In 2003, we started our minimally invasive mitral valve surgery program and from the beginning of our experience a video-assisted right thoracotomy approach has become our first choice for re-operative mitral valve surgery. In the present chapter we review and discuss potential advantage and pitfall of minimally invasive approaches for re-operation on the mitral valve.

Keywords: mitral valve, minimally invasive cardiac surgery, re-operation

INTRODUCTION

An increasing number of patients require redo-mitral valve surgery because patients continue to live longer post-operatively and bioprosthetic valves have become increasingly popular. Furthermore, a large proportion of patients treated with restrictive annuloplasty for functional mitral valve disease, develop recurrence of mitral regurgitation (MR) requiring

* Corresponding Author's Email: michele.murzi@fgm.it.

surgery. Re-operative mitral valve (MV) operations can be particularly difficult in patients with patent coronary bypass grafts, where the risk of graft injury is a significant concern, or previous aortic valve replacement, where exposure of the MV through a sternotomy can be very challenging. Redo sternotomy may also be difficult in patients with vascular structures (brachiocephalic vein, ascending aorta, RV) that lie directly behind the sternum or in patients who had previous sternal wound infections or chest radiotherapy. To improve patient care and reduce the perioperative and intraoperative risk of re-sternotomy, new treatment strategies may be required for such patients. At our center, a video-assisted right mini-thoracotomy (MIMVS) has become the approach of choice for redo MV operations, since 2003 [1]. Early in our experience, we recognized the advantages of this technique in re-operative procedures. Indeed, with this access, the heart, great vessels, and patent bypass grafts are far away from the working field. Less need for surgical dissection can prevent post-operative bleeding, transfusion requirements and need for re-exploration. Furthermore, this approach produces less tissue trauma, less post-operative pain and greater stability of the bony thorax that usually translates in an early mobilization and recovery of the daily activities [2, 3].

PATIENT SELECTION

Contraindication to Redo MIMVS

Clinical evaluation of candidates for redo MIMVS should start with a careful clinical history and assessment of patients. Despite the fact that MIMVS approach can be offered to the vast majority of the patients requiring redo-MV intervention, surgeons embracing this technique should be aware of few conditions that must be considered as potential contraindications:

1. Chest wall abnormalities such as pectus excavatum, or pronounced scoliosis: in these cases exposure of the MV can be extremely difficult.
2. Patients with osteogenic disorders, i.e., osteogenesis imperfecta, should be avoided.
3. Known disease of the pleura or the lung, such as previous pleuritis, pleural calcifications or moderate-severe chronic obstructive pulmonary disease (COPD),
4. Previous right chest surgery.
5. Previous right chest radiotherapy.

All these cases should be evaluated on an individual basis.

PRE-OPERATIVE IMAGING

Chest X-Ray

Chest radiography is a simple yet informative tool for patients' evaluation. In the postero-anterior projection, along with classical radiological signs, we evaluate the ascending aorta

profile, calcification of the aorta, size of the intercostal spaces, pleural calcifications or adhesions, hilar congestion, diffuse lung disease or elevated hemidiaphragm; also abnormalities of ribs or severe deformations of the spine are evident. In lateral projection, the antero-posterior diameter of the thorax and the height of the diaphragm are assessed and it is important to correlate the actual location of abnormalities seen on the postero-anterior view.

Computed Tomography

Computed tomography (CT scan) is a fundamental tool for preoperative planning of the surgical access. In our institution, all the patients scheduled for a redo MIMVS routinely undergo contrast enhanced 64-slice CT scan (Toshiba Aquilon ONE; Toshiba Medical System, Tokyo, Japan) to evaluate the anatomic relationship between the intercostal spaces (ICS), sternum, ascending aorta and MV. Three-dimensional reconstruction of contrast-enhanced CT scan can easily give the surgeon an idea of the operative field. Furthermore it allows to better understand the course of patent bypass grafts and their relationship to the heart.

Ascending aorta calcification is not considered an absolute contraindication for redo MIMVS, but it should be dealt with, with special caution. The CT should visualize the entire vascular tree up to the femoral artery and/or a femoral arterial duplex may be obtained to elucidate the quality of the femoral vessels. Lung and pleural imaging are of utmost importance; CT scan can identify pleural adhesions, plaques, lung bullae, blebs and also lung parenchymal disease; all these features must be taken into account and not overlooked by the surgeon planning redo-MIMVS.

Echocardiography

Standard preoperative trans-thoracic echocardiogram is obtained for all patients, according to the current guidelines [4]. Taking in mind that in a large proportion of this subset of patients, myocardial protection is obtained with hypothermic ventricular fibrillation (VF), information on the status of the aortic valve is crucial. The presence of more than moderate aortic regurgitation (AR) is considered a relative contra-indication for redo MIMVS because of the risk of inadequate cardioplegia delivery and left ventricular distension. Hence, accurate assessment of AR is mandatory to avoid unplanned conversion to a sternotomy during the procedure.

Lung Anatomy and Pulmonary Function

In our experience, the majority of redo MIMVS operations have been carried out without single lung ventilation; mainly to avoid potential complications from lung reperfusion, atelectasis and laryngo-tracheal trauma. Severe COPD, bullous emphysema, adhesions, pleural plaques or parenchymal disease, are considered as contraindication for redo MIMVS. During screening of patients as potential candidate for redo MIMVS, we

recommend CT scan with lung window and pulmonary function tests, due to the fact that breach of pleura is associated with an early decrease in lung function, but with significant improvement after three months.

Angiography

All the patients undergo standard coronary catheterization to visualize the anatomy of the native coronary arteries. In case of disease of one or more coronary arteries, a hybrid treatment strategy consisting of percutaneous treatment for coronary lesions followed a month later, by MIMVS may be performed. The exact timing would depend on clinical, anatomical and angiographic factors. In case of previous CABG, all the grafts are injected during angiography to determine their patency.

SURGICAL TECHNIQUE

Anesthesia and Patient Preparation

The procedure is performed in a standard operating room with each team member positioned according to existing protocols for conventional surgery. General anesthesia is provided according standard protocol for MV surgery. Blood pressure monitoring is obtained through cannulation of radial artery; a standard 4-lumen IV catheter is placed in the right internal jugular vein and a percutaneous sheath (8.5 Fr) introducer is placed to secure an access for endo-cavitary pacemaker lead, if needed. We usually use a single lumen normal tube for intubation. A double lumen endotracheal tube can be used for single (left) lung ventilation if some difficulties during preparation are expected. Transoesophageal echocardiography (TOE) probe is positioned to obtain a clear anatomic image of the MV and its functional morphology, monitor the venous cannula correct insertion/placement, de-airing manouveres and to evaluate the valve function pre- and postoperatively. Two defibrillator pads are placed across the chest wall with the right pad placed under the patients' right shoulder and left pad over the anterior left chest wall to guarantee effective electrical conduction. The patient is placed in a supine position and an air sack is placed under the right scapulae, to allow the patient's right chest to be elevated slightly according to the need of the surgeon for a better working field exposure (Figure 1). This can be useful, particularly in patients with deep chest. This sack can be inflated/deflated enough to lift the right chest upwards/downwards, if required. Patient's right arm should be deviated slightly from the body by shoulder extension and elbow flexion to permit enough space for the placement of the working ports.

The patient's skin is prepared with antiseptic solutions according to the local intra-operative protocol. Draping is accomplished with care to expose: (a) superiorly the right clavicular edge and the pectoral muscle (b) laterally the right anterior axillary line (c) towards the right limb to expose the anterior superior iliac spine and the groin (d) on the left side the sternal notch is exposed and draping continues parallel to the left sternal edge, then laterally

to include the anterior superior iliac spine and the groin. An adhesive aseptic strip is then applied to the exposed areas, thus, minimizing the possible risk of contamination.

Figure 1. Patient position: the right chest is slightly elevated with the use of an air suck.

The Right Minithoracotomy

The procedure is carried out through a mini-thoracotomy in the 3rd or 4th ICS. The decision to pass through the 3rd or the 4th ICS is based on 3D CT scan reconstruction. Access through the fourth ICS usually allows a better exposure of the MV while an incision in the 3rd ICS gives more control on the ascending aorta. The subcutaneous tissue is divided with electrocautery towards the pectoralis major fascia that is incised; careful spread of tissue allows respect for the muscle, less post-operative pain, ease of reconstruction and better functional recovery. The intercostal muscle is then divided in the lateral part of the incision; the surgeon asks for lung deflation and the pleural space is entered gently, taking care to avoid lung injury. At this time, limited adhesion release is performed in an effort to gain enough space to insert a soft tissue retractor and two auxilliary working ports. One 5.5-mm working port is used for a video assistance and for passing the pericardial stay sutures. We prefer to use the same port to avoid further risk of intercostal arteries injury. The port is placed in the same ICS in the mid-axillary line where the thoracotomy incision is made. Another 10.5 mm port is placed two intercostal spaces lower in the mid-axillary line. This port is used for the cardiotomy vent, CO₂ insufflation and for other pericardial stay sutures. Consecutively in order to enhance direct vision, a surgical metallic multi-use retractor (Estech, San Ramon, CA, USA) is inserted and rib spreading is accomplished in a graded manner. At this time, if pleuro-pericardial adhesions are not excessively dense, we prefer to continue surgical dissection before going on cardio-pulmonary bypass (CPB). However, in the event of severe lung adhesions, any attempt to dissect away the lung and the pleura from the thoracic wall may be very cumbersome time-consuming. In these cases, we immediately establish CPB through the femoral vessels, the lungs are deflated and surgical dissection is continued on pump.

Cardiopulmonary Bypass

Based on the conviction that antegrade perfusion is associated with less incidence of neurological complications [5, 6], we prefer to cannulate the ascending aorta directly, whenever possible. In case of a contraindication for ascending aorta cannulation (ascending aorta calcification, ascending aorta far from the incision, patent saphenous vein grafts, severe aorto-pulmonary adhesions, giant right atrium covering the ascending aorta), femoral artery cannulation is chosen as the second alternative. Cannulation of the femoral vessels eliminates issues relating to exposure of the aorta and right atrium and allows CPB to be initiated before the chest is opened. If the ascending aorta as well as the femoral artery are not suitable for cannulation, axillary artery or common carotid artery are used.

Central Aortic Cannulation

Direct aortic cannulation is accomplished using an Easy-flow™ cannula (LivaNova Biomedica Cardio Srl, Sallugia, Italy). Two concentric 2-0 polyester purse string sutures for direct arterial cannulation are placed in a standard fashion into the ascending aorta. The purse string may be reinforced with pledgets, if needed. During the purse-string suture placement, the aorta can be kept steady using locking forceps to reduce the physiological motion. The cannulation site is generally chosen proximal to the transverse sinus, which is the level where the aortic cross-clamp is placed. It is preferable to choose the cannulation site at some distance above the cross-clamp level. After medical induced hypotension, the aortic adventitia is opened progressively with a number 11 blade until intimal layer is exposed; at that point a small incision is made and the cannula is inserted. The Easy-flow™ cannula has an obturator that allows stiffening during insertion and the cannula becomes pliable once the obturator is removed; also a stop ring is available to control the depth of aortic cannulation. This is placed at the marker nearest the tip. After cannula deployment, whilst the assistant still holding the cannula, the first operator secures the cannula with two tourniquets using a silk suture. However, this can be difficult in cases of a deep chest and distant cannulation sites. In these cases, a silk suture previously placed through the tourniquet can facilitate knot-tying inside the chest.

Femoral Artery Cannulation

Exposure of the femoral artery is gained through a 1.5 cm incision placed in the right groin crease. Minimal dissection of the femoral vessels is performed without encircling the vessels. This usually translates in a less probability of groin seroma. A 5/0 prolene pursestring is performed on the superior aspect of the femoral artery and cannulation is performed with Seldinger's technique under TOE guidance. We prefer to cannulate femoral artery employing small wire-wound Bio-Medicus® arterial cannula (17 fr to 19 Fr), (Medtronic, Minneapolis, MN, USA).

Percutaneous Venous Cannulation

Femoral vein is usually percutaneously cannulated with a 7 Fr sheath for later CPB. In our center, this maneuver is done before skin incision and heparin administration in order to minimize bleeding in the event of femoral artery puncture. Femoral vein should be punctured at 4-5 cm lower than inguinal ligament line. This permits a straighter introduction of the

venous cannula into the right femoral vein. A 260 cm guidewire is placed through the venous introducer sheath and is advanced to the right atrium and over the superior cavo-atrial junction under visualization with the TOE probe adjusted to a bicaval view (90–120°). In this particular view, the superior vena cava is on the right and the inferior on the left of the screen; at the top of the screen near the probe is the interatrial septum and left atrium. With the guidewire held in place, the introducer sheath is removed. With a number 11 blade, the puncture site is enlarged and progressive dilators passed to ensure adequate space for venous cannula insertion. It is then advanced into the femoral vein and its tip should be 3–4 cm beyond the superior cavo-atrial junction. The guidewire is slowly withdrawn while holding the cannula in place. The venous cannula sheath is then removed and de-airing accomplished by partially unclamping and expelling blood and any residual air from the lumen before connecting to the venous line of the CPB circuit. One silk stay suture is placed on the skin as a tourniquet over the cannula body to fix it in place and prevent dislodgement. This tourniquet may be easily released and refixed if we need to adjust (push or pull) the cannula during the procedure. The choice of venous cannula gauge is based on patients' weight and surgeons' preference; in our institution we use a range of 22–25 Fr depending on patient's specific nomogram; rarely 19 Fr is used for small patients. Our cannula of choice is the Bio-Medicus® multistage cannula (Medtronic, Minneapolis, MN, USA).

In patients who require additional tricuspid valve or atrial septal defect closure surgery, we use a specifically designed venous cannula. The Remote Access Perfusion Femoral Venous™ cannula (LivaNova Biomedica Cardio Srl, Sallugia, Italy), is a wire-reinforced polymer venous cannula which has two perforated distal sections, separated by a non-perforated segment of 15 cm in length (Figure 2). The two distal sections have multiple holes at multiple stage to allow increased fluid flow and to drain simultaneously both the superior and inferior vena cavae. Appropriate positioning of the perforated sections into both the caval veins is confirmed under TOE guidance [7]. This cannula achieves satisfactory bloodless working field also without occluding the venae cavae and this is of particular importance in redo patients, where placement of caval snares may be particularly challenging through a very small incision. If backflow from the unsnared caval veins is present, a small increase in negative pressure usually results in a relatively bloodless operative field.

Myocardial Protection

Myocardial preservation techniques are key elements for the success of these operations. Frequently, these patients present a variable degree of left ventricular impairment and assuring good myocardial protection is mandatory. At the beginning of our experience we used endo-aortic balloon occlusion but we have gradually abandoned this strategy and use mainly two strategies for myocardial preservation. If the ascending aorta can be safely dissected and clamped, we prefer to do this with a flexible trans-thoracic clamp followed by delivery of antegrade cold crystalloid cardioplegia. In case of patent left internal mammary artery (LIMA) and saphenous vein grafts, ascending aorta calcification, previous ascending aorta replacement and severe adhesions around the ascending aorta, hypothermic ventricular fibrillation (VF) or beating heart is used. A diagram of our operative set-up is showed in Figure 3.

Figure 2. The Remote Access Perfusion Femoral Venous™ cannula (LivaNova Biomedica Cardio Srl, Sallugia, Italy), with two perforated distal section.

Figure 3. Diagram of our favored operative setup.

Endoarteric Balloon

Early in our experience, endoarteric balloon occlusion with antegrade cardioplegia delivery was our preferred strategy for redo MIMVS. If this strategy is chosen, the femoral artery is cannulated with a dedicated “Y” shaped cannula that allows the insertion of the balloon through an additional branch. The balloon is advanced into the ascending aorta and inflated 2 cm above the sinotubular junction under TOE control. Cold crystalloid cardioplegia is delivered through the tip of the balloon. Currently, in our practice, the endoclamp is used only in those cases where the aorta cannot be clamped and moderate AR is present. Achieving aortic occlusion with the endo-balloon still represents a challenge. The occlusive balloon must be positioned under TOE guidance just above the sinotubular junction and the catheter tip must be controlled continuously. Balloon dislodgment can cause innominate artery occlusion, potentially causing neurologic injury or prolapse into the left ventricle (LV) with suboptimal myocardial reservation. In addition when stitching on the mitro-aortic continuity, inadvertent balloon injury is possible.

Direct Aortic Cross-Clamping with Cold Crystalloid Cardioplegia

For most redo MIMVS, myocardial protection is obtained with direct transthoracic clamping and antegrade cold crystalloid cardioplegia. We use the Cygnet® flexible aortic clamp (Novare Surgical Systems, Inc., Cupertino, CA). The rigid shaft of the clamp enables tunnelling and accurate clamp jaws placement. Once properly placed, the rigid shaft retracts

leaving a flexible neck, which can be manoeuvred to a place remote from the surgeon's working field. After reducing the pump flow, the transverse sinus is gently dissected and with the aid of an external sucker, the aorta is gently elevated and the inferior jaw of the clamp is advanced. It is of particular importance to avoid inadvertent injury to the left atrial appendage and pulmonary artery during this step. Once the correct position of the jaws is verified, the aorta is clamped and full CPB flow is reestablished. Cardioplegia is delivered antegradely with a long dedicated catheter placed in the ascending aorta.

Hypothermic Ventricular Fibrillation

If VF heart surgery is used instead of aortic cross-clamping, the patient is cooled down to 28 C°. If the heart does not fibrillate spontaneously, when the target bladder temperature is reached, VF is induced with an electrical fibrillator. The left atrium is opened and an additional pump sucker is inserted into the LV to prevent distension and inadvertent ejection. In patients with mild AR or previous mechanical aortic valve replacement, a variable volume of blood can return from the aorta, obstructing the surgical view. In these cases additional cooling with reduction of pump flow represents a successful strategy to reduce blood return and speed up the procedure. The main risk associated with VF is represented by inadvertent air embolization. For this reason we vent the aorta whenever possible.

In patients with impaired ejection fraction, a beating heart strategy is employed. The patient is cooled to 32C°, aorta is vented and after pharmacologically-induced bradycardia the left atrium is opened. A second trans-mitral vent is immediately inserted into the LV to avoid inadvertent ventricular distension and air embolization.

Management of Patent LIMA to LAD Graft

Redo MIMVS in the presence of patent LIMA graft, represents a particular challenge because these cannot be isolated through a right mini-thoracotomy. In this subset of patients, we routinely use systemic cooling and VF and we are satisfied with this strategy. However in few cases we have used cross-clamping with cold crystalloid cardioplegia and moderate systemic cooling to 32C°, leaving the mammary graft patent. As reported by other authors, we have not experienced significant problems with this strategy [8].

Mitral Valve Exposure

The MV is exposed through a standard left paraseptal atriotomy, with the aid of an atrial retractor supported by an external mechanical arm. The arm is inserted in the thorax through a right parasternal hole performed in the fourth ICS. After left atrial retraction, it is important to monitor the central venous pressure and the position of the venous cannula, to detect inadvertent cannula obstruction or dislodgement. In presence of an aortic valve prosthesis, exposure of the MV can be difficult. In these cases we prefer to insert the arm of the atrial retractor through a parasternal hole in the fifth or sixth ICS. This allows to retract the left atrium more caudally and to avoid conflict between the atrial retractor blade and the aortic prosthesis.

Mitral Procedure

The right mini-thoracotomy permits to obtain a straight access to the MV and guarantees safe and excellent view of all the valve apparatus allowing all types of repair techniques such as neochordal placement and anterior leaflet repair (Figure 4). The right chest approach does not impede the replacement of a mitral prosthesis or the repair of paravalvular leak.

Figure 4. Surgeon's view of the mitral vave.

In our center, this technique has been employed routinely in patients with active endocarditis. However, in this subset of patients, it is extremely important to confirm the absence of any trigone or aortic valve involvement pre-operatively.

De-Airing the Heart

Meticulous cardiac air removal is extremely important in redo MIMVS, because the heart can not be manipulated and frequently the apex is attached to the thoracic wall by adhesions. Frequently the air tends to be retained into the cardiac apex and along the ventricular septum. In effort to reduce the amount of cardiac air, we routinely use CO₂ insufflation into the thorax through a small cathether inserted via the 10.5 mm thoracic port. The CO₂ released is started before the opening of the left atrium. The volume of CO₂ insufflation is 1 liter/m.

At the end of the mitral procedure, a cathether vent is placed into the LV through the MV. Deairing the heart is obtained with a two-stage procedure. First, the table is lifted head up, the heart is filled, both lungs are ventilated and air is removed from the left atrium with a small forceps inserted through the suture line. Consecutively the bed is then placed head down, the aortic calmp is released and air is removed with suction on the tran-smitral vent and the aortic vent. The trans-mitral and aortic root vent are left in place until the heart is fully beating and no more air is seen on TOE.

Pacing Wires

In all patients, a preoperative percutaneous sheath (8.5 Fr) introducer is placed through the jugular vein, to secure access for endo-cavitary pacemaker lead. However, if needed, epicardial pacing wires can be positioned on the right ventricle (RV), with the heart empty on full CPB. The wires are then exteriorized through the parasternal hole, used for left atrial retractor stabilization. In case of tricuspid valve procedure, an endocardial wire can be positioned into the RV through the tricuspid valve and exteriorized through the right atriotomy suture line.

Institutional Experience

Between 2003 and 2016, 197 patients underwent a reoperative MIMVS at our institution. Mean time to redo surgery was 7.2 ± 3.6 years. For 24 patients this was the third intervention, in 6 was the fourth and in 1 the seventh. Mean preoperative Euroscore was 12.4 ± 4.2 . The operation was performed with direct ascending aorta cannulation in 74 patients, femoral artery cannulation in 121 and axillary artery in 2. Myocardial protection was achieved with aortic clamping (transthoracic clamp in 61 patients and endo-aortic balloon occluder in 73) and cold crystalloid cardioplegia. The remaining patients underwent operations during hypothermic VF ($n = 41$; 13.2%) or beating heart ($n = 22$; 11.5%). Mean cardiopulmonary bypass and aortic cross-clamp times were 160 ± 48 min. and 82 ± 49 min. Conversion to sternotomy was required in 3 patients during the procedure: in one patient due to atrioventricular disruption and in 2 due to extensive adhesions on the chest wall. A MV repair was performed in 66 patients and MV replacement in 131. The 30-day mortality rate was 5% ($n = 10$). Causes of death were low cardiac output syndrome in 3 patients, multiorgan failure in 1, neurologic complication in 2 and sepsis in 1. Stroke was observed in 13 patients (6.5%). This was transient in 10 and permanent in 3. Early reoperation (<30 days) was necessary in one patient due to valve repair failure. The operation was re-performed through the right mini-thoracotomy and the valve was re-repaired. Blood transfusions were required in 79 patients (40%) and the mean unit transfusion/patient was 1.3 ± 1.1 . Mean follow-up was 3.8 ± 2.4 years and 100% complete. Late death occurred in 21 patients. There were 2 late re-interventions at for mitral prosthesis endocarditis. Survivals at 1, 5 and 10 years was $92.8 \pm 1.8\%$, $85.3 \pm 2.1\%$, and $77.3 \pm 3.2\%$, respectively.

CONCLUSION

A right mini-thoracotomy permits direct access to the MV without the need of extensive cardiac mobilization which is required in conventional redo procedures. The minimally invasive approach guarantees safe and excellent view of the entire valve apparatus allowing all types of repair techniques such as neochordal placement and anterior leaflet repair. The avoidance of extensive surgical dissection, good exposure of the valve, low requirement of blood transfusion and low hospital stay are the main advantages of this technique.

Chapter 424

VALVE REPAIR TECHNIQUES IN MINIMALLY INVASIVE MITRAL SURGERY

Loris Salvador, MD and Tommaso Hinna Danesi*, MD

Cardiac Surgery Unit, San Bortolo Hospital,
Vicenza, Italy

ABSTRACT

Over the past 15 years, minimally invasive cardiac surgery (MICS) has been increasingly adopted, especially with mitral valve (MV) surgery. A variety of different surgical approaches are described as minimally invasive, but may be substantially different one from another. More recently, the trend of surgical wound reduction requires surgery performed with indirect vision techniques where the application of the thoracoscope has become pivotal. This is the era of endoscopic minimally invasive cardiac surgery (endoscopic MICS). This surgery requires specific surgical skills and a complete knowledge of the mitral valve apparatus, pathology and repair techniques. All aspects of cardiac surgery are involved in this innovative procedure, including the anesthesiological and cardiopulmonary by-pass setups. Performing surgery using videoscopes with long shafted instruments requires reassessment of and adaptation to the different MV repair techniques aimed at approaching the mitral apparatus in a simpler way. Good experience in MV repair using e-PTFE artificial chordae with an associated annuloplasty may facilitate the developing of an endoscopic MICS program in MV repair and can be the optimal solution in about 90% of patients with degenerative mitral regurgitation.

INTRODUCTION

Over the past 15 years, minimally invasive cardiac surgery (MICS) has been increasingly used, especially for mitral valve (MV) surgery. This growth has been driven by a desire to translate the benefits observed in other types of minimally invasive surgery, such as decreased pain, reduced surgical trauma, faster recovery and meeting the patient's needs, to cardiac surgery. The initial enthusiasm was tempered by the difficulties of performing complex operations through a small incision, a reduced operating field with no dedicated technology, rudimentary minimally invasive instruments and the compelling need of avoiding longer cross clamp time. However, innovation in perfusion techniques and devices and the development of dedicated instruments has made way to establish minimally invasive valve surgery (mitral, aortic and tricuspid) the standard of care in high volume centers in the current era.

MICS has undergone several changes with regards to techniques and philosophy. Surgical incisions, valve repair techniques including cardio-pulmonary bypass (CPB) and surgical instruments have been continually evolving, making MICS easier and reproducible, with surgical results comparable to the-conventional surgical approach. In this chapter, MV repair (MVr) techniques in minimally invasive surgery will be explored. In the context of this chapter, minimally invasive mitral valve repair refers to surgery that is performed totally endoscopic under indirect vision where the use of a thoracoscope is mandatory; we define this surgery as Endoscopic MICS.

MINIMALLY INVASIVE CONCEPT: MICS AND ENDOSCOPIC MICS

There are several interpretations of the minimally invasive concept (Figure 1, Figure 2 and Figure 3).

Figure 1 shows a right anterior thoracotomy (RAT), in which the divarication of the ribs provides a larger operative field and surgery can be performed under direct vision. Figures 2 and 3 show a minimally invasive right anterior mini-thoracotomy (MRAT). Both approaches are intended as minimally invasive but there are several differences. First of all in the MRAT, the thoracoscope is mandatory to perform surgery, otherwise the reduced incision size does not allow to preserve the natural stereo-vision and often the MV itself cannot be directly visualized. This chapter will discuss only surgery performed under MRAT in which the small skin incision serves only to introduce endoscopic surgical instruments and cardiac devices as annuloplasty rings or prosthetic valves. This is done without any excessive rib spreading with the aid of a soft tissue retractor. The use of thoracoscope with indirect vision, the minimal skin incision, and no rib spreading are characteristics of endoscopic minimally invasive mitral valve repair (MIMVr). Rib spreading leads to post-operative pain ignoring one of the key principles of MIMVr which is pain avoidance.

Figure 3.

GENERAL CONSIDERATIONS

From the Society of Thoracic Surgeons database, a minimally invasive valve surgery approach is defined as “any procedure not performed with a full sternotomy and CPB support” [1]. According to Chitwood et al. [2], MICS should not be defined in terms of a specific procedure, but rather a “philosophy” that requires an operation-specific strategy. Each minimally-invasive strategy introduces alternatives for CPB cannulation (central or peripheral), aortic occlusion (endovascular or transthoracic), and cardioplegia delivery (antegrade, atrial retrograde or transjugular retro-retrograde) [2, 3]. The concept of surgical access avoiding full sternotomy or a “philosophy” that requires specific surgical strategy translates into a wide range of surgical procedures in which a partial sternotomy and a full right thoracotomy are both considered minimally invasive surgery.

Preoperative assessment of MIMVr patients is still debated i.e., several centers consider a full aortic CT scan mandatory to assess the feasibility of femoro-femoral cannulation, the possibility to change surgical strategy or consider other options than surgery [4, 5]. Considering the risk factors of the population undergoing MIMVr and that 60-70% of mitral regurgitation (MR) is due to degenerative disease in a relatively younger age group, a preoperative CT scan could be considered useful to detect ascending aortic calcification affecting aortic cross-clamping as well as prediction of peripheral cannulation-related complications [6]. To establish a new surgical procedure as routine all non-surgical and surgical steps must be standardized to achieve consistent outcomes.

Anesthesiological set-up is not very different from conventional cardiac surgery. Although double lumen endo-tracheal intubation is widespread, this is often not mandatory. A retrospective review on 96 pts who underwent MICS using a single lumen tube or double lumen tube did not show any difference in intensive care unit stay or failure in fast track protocols [7]. Double lumen endo-tracheal intubation should be considered in patients with previous sternotomy and is mandatory in redo patients with a previous right thoracotomy. Central venous cannulation can be achieved through either the right or the left internal jugular veins. The right subclavian vein should be generally spared in order to avoid any interference with the thoracoscope which may be placed at the 2nd intercostal space (ICS). The right internal jugular vein may need to be avoided if percutaneous superior vena cava venous drainage is needed for CPB. Cannulation techniques for MIMVr have constantly evolved over the last few years. Until 2010, cannulation strategy evolved in our experience to favor central ascending aortic over peripheral femoral cannulation, percutaneous dual-stage bicaval venous drainage over percutaneous neck access and direct external aortic cross-clamp (AoX) over the endo-aortic balloon occlusion [8]. To have a clear consensus on the exact cannulation approach to CPB and aortic occlusion is not simple because there are not clinical randomized trials and the retrospective series published to date include a large variety of surgical approaches defined generically as minimally invasive. Currently, the commonest MIMVr approach is port-access, performed through a RAT or a MRAT depending on the center preference or experience (direct vs indirect vision). Because the endoscopic MIMVr is more attractive for both patients and surgeons, CPB institution through peripheral cannulation with the utilization of the endo-aortic balloon occlude is a growing-option.

MITRAL VALVE ACCESS IN ENDOSCOPIC MIMVr

In MIMVr, the choice of the skin incision and the ICS in the RAT is crucial, in order to achieve comfortable surgical procedure. In port-access surgery the 4th or 5th ICS is usually entered through a submammary skin incision performed laterally and posteriorly from the anterior axillary line (Figure 4). This approach allows direct vision surgery in which the thoracoscope serves mainly as light source and assists with the surgical procedure. Typically, this is known as *video-assisted mitral valve surgery*. The incorrect ICS or a very medial mini-thoracotomy can result in an uncomfortable setup and may lead to conversion into a median sternotomy. In male patients undergoing endoscopic MIMVr, the skin incision is performed following the lateral half of the areola of the nipple and the ICS used to enter the pleural space is immediately under the pectoralis and intercostal muscles (Figure 5). Usually this is the 3rd or the 4th ICS and if the diaphragm is not too high, this is the best approach to the MV. A soft tissue retractor is enough to obtain an adequate separation of the ribs needed in order to handle surgical instruments and insert an annuloplasty ring or valve prosthesis.

Figure 4. PortAccess MV surgery landmarks. From Jacobs S., Sündermann S. H. *Ann Cardiothorac Surg* 2013;2(6):818-824.

In female patients, the skin incision is performed in the right submammary line and the glandular tissue is gently dissected at its base to enter in the right ICS that usually lies 5-6 cm cephalad to the skin incision. It is preferable to enter the ICS lateral to the mid-axillary line, to achieve a straight trajectory to the MV annulus. Here, the 30° thoracoscope is essential which provides a magnified surgical view (Figure 6) and allows to “navigate the mediastinum” and access cardiac structures which are sometimes hard to display in conventional surgery i.e., pulmonary veins and the Sondergaard groove. The thoracoscope is very useful in left atrial access; in endoscopic MIMVr, the MV is accessible through a left atriotomy performed on the Sondergaard groove at the conjunction between the right upper pulmonary vein with the left atrial wall just below the interatrial septum. The atriotomy should be cranially extended just below the superior vena cava (SVC), and downwards 1 or 2 cm from the origin of the inferior vena cava (IVC). Once the left atrium (LA) has been

opened an atrial retractor can be inserted and the MV is exposed. Careful attention must be paid to avoid any injury to the right internal mammary artery during insertion of the trans-thoracic shaft to which the atrial retractor is fixed. When retracting the LA, it is important to check that the venous drainage is satisfactory, as the venous cannula could dislodge during this maneuver.

VALVE REPAIR TECHNIQUES IN MIMVr

MV repair (MVr) has become the procedure of choice for degenerative MR, with superior results compared to MV replacement (MVR) [9-10]. MVr is feasible in as many as 95-99% of cases of degenerative MR, [11-14] despite the presence of complex lesions. The aim of MVr is to restore sufficient coaptation surface. This is the essence of Carpentier's lesson from his "French Correction" article [12]. The Carpentier quadrangular resection, with or without concomitant sliding plasty has been considered the standard surgical technique to correct posterior leaflet prolapse (Figure 7). New paradigms have risen for the reconstruction of the posterior leaflet: the "respect rather than resect" approach in which the MV apparatus is respected and any resection is avoided, is now frequently adopted. As leaflet tissue is the basic component of the coaptation surface, the logical corrective approach is to preserve the valve tissue and transform it into a large, regular and smooth coaptation surface [15]. Various types of reconstructive procedures, including triangular resection, chordal transfer, chordal shortening, edge-to-edge technique and papillary muscle repositioning have been used to repair anterior leaflet prolapse [13, 14-23].

Figure 7. Carpentier's Quadrangular resection of P2 with sliding annuloplasty.
From www.mitralvalvrepair.org.

Posterior Leaflet Prolapse Management

In the setting of posterior leaflet prolapse (PLP), the repair techniques proposed by Carpentier are the classical quadrangular resection of the prolapsing P2 segment with annular plication [16] or the sliding leaflet plasty [17]; several variations of this technique have been

adopted to answer questions arising from the complex world of MVr, such as ‘how large should the resection be?’ ‘what if the prolapse involves the entire P2 in a very large P2?’ ‘what about two tiny leaflets remnants after P2 resection?’ ‘what if the prolapse involves an additional scallop?’ ‘should the annular plication give a risk of circumflex artery kinking?’ The results were a variety of complex resection patterns from a simplified triangular resection of prolapsing P2 to a “The Fleur De Lys” technique for PLP. This technique has been designed to repair only the pathological components of the typical “floppy” mitral valve which include a thinning of the belly of the prolapsing scallop, whereas the basal region of the leaflet is thick and normal. the technique is founded on the ascertainment that there is typically an absence of secondary chords in the prolapse belly and the neighboring primary chords are either ruptured or thin and elongated and thus failing to control the affected leaflet edge. The technique is a variation of the “triangular resection.” The fleur De Lys concept, visualizing each scallop as a “Fleur De Lys,” does give the surgeon the sense of the curves rather than straight-line V resection to be performed as well as the areas of more normal tissue as represented by the right and left fronds (Figure 8) [18].

Figure 8. Conceptually each scallop can be visualized as a Fleur de Lys. The resection of the abnormal middle component of the middle scallop is curvilinear and the obverse to the middle Fleur de Lys frond. In actuality, the resection does not come to a point but is really more trumpet-shaped.

While the resecting technique excises the redundant valve tissue, the conservative technique employs expanded polytetrafluoroethylene (ePTFE) sutures (GORE-TEX sutures; W.L. Gore & Associates, Inc, Flagstaff, Ariz) to replace ruptured or elongated native chordae reducing the prolapsing segments. e-PTFE was introduced experimentally by Frater and colleagues in the early 1980s. Current use in clinical practice has permitted repair of complex mitral lesions, including anterior leaflet or bi-leaflet prolapse. This has now been widely adopted in clinical practice [21-22]. The commonest caliber of artificial chordae used to replace the native MV chordae is the 5/0 CV Gore-Tex suture. Long term results of MVr with artificial chordae are excellent and this has become the standard repair technique in many experienced centers. Figure 9 and 10 show 15 year survival and freedom from re-operation of patients treated with e-PTFE neochoord implantation [84% (95% CI 75-90%) and 92% (95% CI 87-95%), respectively]. The freedom from moderate MR recurrence was 85% (95% CI 78-91%) (Figure 11). At 12 years from first operation the artificial e-PTFE chordae are seen to be similar to the native chords in Figure 12 [23]. This efficient technique is particularly

suitable for the endoscopic MIMVr approach. After many years of MVr with artificial chordae implant, the number of implanted neochords have been progressively reduced in our experience. In the study from Salvador et al. [23], which included patients from 1986 to 2006, an average of 6 pairs (4-8) of e-PTFE neochords were placed. Nowadays perform MVr routinely using 2 or 3 pair of neochords. This number is able to reduce prolapsing segments and give a smooth and regular coaptation surface, allowing the anterior leaflet to evenly release the forces along the coaptation rim.

The length of the implanted e-PTFE neochords is still a matter of concern for some surgeons. Many published papers have proposed a variety of instruments and techniques in order to assess the adequate length of the artificial chordae. This can be estimated pre-operatively on echocardiographic basis with the healthy natural chordae as the reference point and/or intraoperatively with specific calipers [24-25].

Figure 13. Techniques for the repair of the posterior or both mitral leaflets. The figure panel shows the essential steps of the techniques detailed in TABLE 1 for the repair of the posterior (or both) MV leaflet(s). From M. Ibrahim et al. / *Interactive CardioVascular and Thoracic Surgery* [25].

Figure 13 shows the essential steps in posterior or bileaflet MV repair detailed in Table 1. It is immediately apparent as many of the aforementioned techniques may not be easily reproducible in an endoscopic MIMVr setting. Our experience in conventional MVr lead us to adopt a simplified technique, in which only 2 or 3 pairs of e-PTFE artificial chordae are placed to reduce the PLP segment. The artificial chordae are passed through the papillary muscle with an e-PTFE pledget parallel to the long axis of the muscle itself (Figure 17 and

18) in order to avoid any injury to the vascular system of the papillary muscle. The two tips of the neochoord are passed twice at the level of the free edge of the prolapsing segment to obtain a modifiable but stable provisional fixation of the neochoord. In this way the length of the e-PTFE chord can be easily modified during the saline test (Figure 19-20). Once the valve repair has been completed and the saline test is satisfactory, the artificial chordae are tied. If the P2 segment is too long and there is a real risk of systolic anterior motion (SAM) of the anterior MV leaflet, the free edge of the prolapsing segment of P2 is excised. In this way the posterior leaflet will be lower in height. The e-PTFE neochoordae are then implanted at the resected zone of P2.

Figure 17. Under filled left ventricle the length of the e-PTFE neo-chord can be easily adjusted.

Anterior Leaflet or Bileaflets Prolapse Management

Anterior leaflet (ALP) or bileaflet prolapse (BLP) are deemed to require a more complex correction in comparison with PLP which is reflected in the associated valve repair durability in the long term [11-31]. A large armamentarium of surgical techniques is available for repairing these lesions, such as chordal transfer or shortening, e-PTFE neo-chordae implantation, papillary muscle repositioning, leaflets resection and edge-to-edge technique. The choice of the right “height” of the anterior leaflet remains the crucial discussion point-of ALP repair to the extent that trans-aortic approaches have been proposed to correct this [32]. Due to the difficulties in its management, the use of e-PTFE neo-chordae was first studied in the treatment of the PLP and its application was then extended to ALP and BLP [33]. We

know that isolated ALP or BLP are independent predictors of MR recurrence [19]. Hence, to solve the complexity of treatment of these type of lesions, a large number of operative techniques, instruments and calipers have been purposed. Table 2 show several methods of anterior leaflet repair.

From M. Ibrahim et al. / Interactive CardioVascular and Thoracic Surgery [25].

In Figures 18A, B, C are shown the essential steps of the techniques detailed in Table 2 for repair of the anterior mitral valve leaflet. In our experience of MVr, isolated ALP is quite rare. BLP is more common, consisting of around 30% of degenerative MR [33]. Usually precise reduction of PLP with e-PTFE neochordae implantation completed with a posterior annuloplasty can yield a perfectly competent MV without any intervention on the prolapsing anterior leaflet. This is due to the realization of a large and smooth coaptation surface after the “repositioning” of the posterior leaflet with artificial chordae and to the shifting forward the septum of the coaptation line that does not allow the anterior leaflet to prolapse again. If the native chordae relative to the anterior leaflet are elongated, reduced in number or too thin, a sentinel pair of e-PTFE neochord can be placed. The height is determined by referring to the native annulus.

Figure 18A. Techniques for the repair of the anterior mitral leaflet.

Figure 18B. Techniques for the repair of the anterior mitral leaflet.

Figure 18C. Techniques for the repair of the anterior mitral leaflet.

Native MV Annulus Management

The management of the native MV annulus is fundamental in the setting of MVr. It is well known that lack of mitral annuloplasty [19] or no use of annuloplasty ring during MVr surgery are independent predictors of recurrent MR [20]. Other independent predictors of MV reoperation are shown in Table 3.

Several prosthetic rings are available for use in MVr in degenerative MR. Characteristics varies from model to model: open or closed; soft, rigid or semirigid; planar or saddle shaped. The device of choice depends on the surgeon's preference and experience. We usually employ soft open rings in order to preserve the physiological function of the mitro-aortic junction and to leave the mitro-aortic continuity undisturbed. Soft bands or semirigid closed rings can also be reshaped once they have been implanted to correct for instance asymmetrical annular enlargements. The development of precise 3D echocardiography has provided us with a new tool for MV analysis. For instance real-time three-dimensional TEE has increased our understanding of the distinct mechanisms underlying functional, ischemic or degenerative MR. In case of fibro-elastic deficiency (FED) or in Barlow's Disease (BD), the annular motion is substantially different. In FED, the saddle-shape and contractile function is relatively preserved, while in BD the annulus is remarkably flattened and hypodynamic. these findings may influence the choice of the repair technique and the selection of a particular annuloplasty ring [62]. The ring type and the size is related to the underlying MV disease (i.e., FED, BD) and is crucial in the position and reshaping of the MV coaptation that is due to the coaptation surface, the repositioning of the coaptation point among the antero-posterior MV diameter, and the coaptation depth (the distance from the annular plane to effective point of coaptation into the left ventricle). All these aspects are involved in a successful MVr (Figure 19).

Table 3. Independent predictors of MV reoperation

	Hazard Ratio (95% CI)	P value
Isolated anterior leaflets prolapse	5.04 (2.51-10.9)	<0.001
Myxomatous degeneration (per level)	1.54 (1.02-2.32)	0.04
Duran ring annuloplasty	3.23 (1.67-6.25)	0.001
Independent Predictors of recurrence of moderate/severe MV regurgitation		
Age by 5-y increments	1.33 (1.20-1.46)	<0.001
Isolated anterior leaflet prolapse	2.86 (1.66-1.90)	<0.001
Myxomatous degeneration (per level)	1.57 (1.19-2.07)	0.002
Repair without annuloplasty ring	2.13 (1.21-3.75)	0.009
CPB time (per 10 min)	1.11 (1.03-1.98)	0.007

From David TE, Armstrong S, McCrindle BW, Manlhiot C. 2013. Late outcomes of mitral valve repair for mitral regurgitation due to degenerative disease. *Circulation*. 127(14):1485-92. [19].

Anterior shifting of mitral leaflet coaptation toward the left ventricular outflow tract (LVOT) may lead to systolic anterior motion (SAM) and LVOT obstruction (LVOTO). The position of the coaptation line of the mitral leaflets is a dynamic condition and hence a potential target and end point for surgical strategies to prevent SAM/LVOTO post MV repair [63]. Some valvuloplasty techniques are more suitable to increase the risk of SAM in the post CPB period; for instance, the residual leaflet length strictly correlates with the degree of SAM. According to this study and that of Lee et al. [64], it should be expected that the “sliding leaflet technique,” associated with quadrangular resection, as proposed by Jebara et al. [65], should reduce the incidence of SAM and LVOTO. By decreasing the size of the posterior mitral leaflet, coaptation will occur closer to the tip of the anterior leaflet and more posteriorly in the ventricular cavity, leaving less mitral tissue near the LVOTO [66].

AL = anterior leaflet length; Ann Diam = annular diameter; CoaptAnn = distance from the mitral coaptation point to the annular plane; CSept = distance from the mitral coaptation point to the septum; LVIDs = left ventricular internal diameter in systole; PL = posterior leaflet length.

Figure 19. Schematic demonstrating the transesophageal echocardiographic measurements performed prior to and after mitral valve repair. The image was obtained from the esophageal location at zero degrees (horizontal) plane. Structures included the left atrium, left ventricle, mitral valve and the left ventricular outflow tract. Lengths of the anterior and posterior leaflets were obtained using the central scallops. From Adrew D. et al. [63].

In endoscopic MICS, performing surgery may be technically more challenging. However, the assessment of the valve is better than the standard sternotomy approach due to thoracoscopic magnification. The new generation of 3D systems for thoracoscopic surgery provide the feeling of depth that is lost with the traditional two-dimensional systems. Furthermore, the analysis of prolapsing segments, leaflet length and mobility and the determination of artificial neochordae length is facilitated by the use of videothoracoscopy.

Figure 20. A, B, C Preoperative Echocardiogram - D, E, F postoperative Echocardiographic result [68].

Figure 21. A: Anterior MV leaflet (AML) detachment from its base, B-C: LVOTO excision; D: reconstruction and elongation of the AML with a xeno pericardial patch; E: final result AML [68].

As mentioned above, we are used to implant open soft mitral band in order to leave the mitro-aortic junction free and also to preserve the ability of subsequent modification of the ring size, if needed. The ring size choice is based on the annular diameter and shape (symmetrical or asymmetrical dilatation), on the posterior and anterior leaflet length and on their motility during the cardiac cycle and on the LVOT diameter and shape. The risk of SAM drives the choice towards an oversized ring, whereas the length of the posterior and anterior leaflets and the need for reduction of the antero-posterior annular diameter to achieve

coaptation may lead to an undersized ring. In the setting of degenerative MV disease a closed ring is usually chosen when a subsequent MV replacement may be contemplated. The MEMO 3D and MEMO 3D Rechorde (Sorin-Livanova; London, UK) are semirigid closed mitral rings, that are very suitable for a valve-in-ring transapical procedure because of their ability to assume a perfect circular shape once the expandable valve has been released [67]. More complex techniques involving MV leaflets can be performed in endoscopic MICS; for example closure of pseudocleft with 6/0 GORE-TEX (GORE-TEX sutures; W.L. Gore & Associates, Inc, Flagstaff, Ariz) between two scallops to seal the coaptation surface; or a more complex extension of the anterior leaflet with pericardial patch and enlargement of the LVOT achieved by transmitral myectomy in order to avoid SAM and give a more natural movement of the leaflet during the cardiac cycle. The elongation of AMVL with patch is also used to “stiffen” the anterior leaflet thus reducing leaflet laxity, Figure 20A,B,C,D,E,F is representing pre and post-operative echocardiographic assessment Figures 21A, B, C, D, E represent intraoperative pictures [68].

ABSTRACT

During the past two decades, the increasing popularity of minimally invasive techniques has had a dramatic impact on the surgical treatment of cardiac disease. Advances in endoscopic imaging and surgical instrumentation have enabled cardiac surgeons to perform complex procedures through small incisions. This chapter will summarize the current guidelines for surgical management of tricuspid valve disease and demonstrate our minimally invasive atrial fibrillation ablation (Cox-Maze IV procedure) technique for both stand-alone atrial fibrillation ablation and for patients undergoing concomitant tricuspid valve and/or mitral valve surgery. We will also discuss surgical results.

Keywords: tricuspid, atrial fibrillation, ablation

INTRODUCTION

Tricuspid valve (TV) disease often coexists with other valvular disease [1]. Functional incompetence of the TV, the most common condition, is commonly asymptomatic but progresses with time and may lead to annular and right ventricular (RV) dilatation. TV disease has been considered less clinically important than mitral or aortic valve pathology, and its management remains controversial [1]. Patients are only occasionally referred for isolated TV surgery, and most procedures are performed concomitant with other cardiac

* Corresponding Author's Email: damianor@wustl.edu.

operations. A minimally invasive surgical approach is feasible in most patients and is a very good approach to re-operative TV surgery in patients with a prior sternotomy and patent bypass grafts.

Table 1. Primary causes of tricuspid valve disease [2]

Tricuspid valve regurgitation
– Ebstein’s anomaly
– AV canal defect
– Myxomatous degeneration
– Endocarditis
– Trauma (including iatrogenic)
– Tricuspid valve stenosis
– Congenital tricuspid atresia

Table 2. Secondary causes of tricuspid valve disease [2]

Tricuspid valve regurgitation
– Left-sided heart lesions (aortic valve disease, mitral valve disease)
– Congestive heart failure
– Pulmonary embolism
– Pulmonary hypertension
– Rheumatic heart disease
– Marfan’s syndrome
– Right-sided ventricular infarction
– Tricuspid valve stenosis
– Carcinoid syndrome
– Rheumatic heart disease
– Right atrial myxoma
– Lupus erythematosus
– Endomyocardial fibrosis

INDICATIONS FOR TRICUSPID VALVE SURGERY

Tricuspid valve disease can arise from a variety of primary (Table 1) and secondary (Table 2) mechanisms. However, the management of the diseased TV is primarily determined by whether the primary physiology is stenosis or regurgitation.

Tricuspid Valve Regurgitation (TR)

TR is common and can arise from various causes. Primary TR is seen with congenital anomalies or acquired leaflet defects. Secondary TR develops in the setting of pressure

overload (primary or secondary pulmonary hypertension) or RV cardiomyopathies (infarction). Functional TR, defined as TR with an anatomically normal valve, is the most common form of tricuspid dysfunction. When the degree of regurgitation worsens, progressive volume overload distends the RV and the tricuspid annulus, producing more severe TR.

Because TR can vary in response to preload, afterload, and RV function [3], echocardiography and pulmonary artery pressure estimation are central to determining its management. It has been suggested that a tricuspid annulus diameter >40 mm (or 21 mm/m^2 measured in the 4-chamber view) indicates the need for TV repair (TVr) [4]. According to the European Society of Cardiology's (ESC) Guidelines on the Management of Valvular Heart Disease, "adding a tricuspid repair, if indicated during left-sided surgery, does not increase operative risks." [4]. The 2014 American Heart Association/American College of Cardiology guidelines recommend performing TV annuloplasty or replacement in patients with severe TR at the time of left-sided valve surgery (Class I) and TV annuloplasty for less than severe TR in patients with pulmonary hypertension or tricuspid annular dilatation undergoing left-sided valve surgery (class IIB) [5]. Tricuspid annuloplasty or replacement is reasonable for patients with severe primary TR who are symptomatic (Class IIa) and may be considered in asymptomatic patients with progressive right ventricular dysfunction (Class IIB).

Late onset TR can reflect intrinsic RV dysfunction or tricuspid annular dilatation. Functional TR has been found in up to 67% of patients undergoing left-sided valve surgery and is thought to be caused by increased afterload from left-sided heart pathology [6]. TR may progress after surgery if the TV is left untreated in patients with less than severe TR. Matsuyama et al. [7] reported significant TR (at least grade 3) on echocardiography performed late after mitral valve replacement (MVR) in 37% of patients with preoperative grade 2 TR. The incidence of echocardiographically moderate or severe late TR in rheumatic patients is even higher (68%) [6]. TR is diagnosed late after MVR, 10 years on average, but can appear as late as 24 years after the initial surgery [6, 8]. The ACC/AHA guidelines recommend considering reoperation for TR only if the regurgitation is severe and symptomatic, RV function is preserved, and severe pulmonary hypertension does not coexist (Class IIB) [5].

Although late TR has been reported most often in patients with rheumatic heart disease, it is not confined to rheumatic patients [9, 10]. Moderate or severe TR was reported in as many as 74% of patients three years after surgical repair of ischemic mitral regurgitation (MR) [10]. Dreyfus et al. [9] reported 34% late TR (grade 3 or 4) in a group of 163 patients with mixed MR etiology who were followed for five years after MV repair (MVR).

Tricuspid Valve Stenosis (TS)

TS produces a mechanical obstruction to right ventricular (RV) filling [11]. TS can be caused by rheumatic inflammation and accompanies rheumatic mitral stenosis in up to 30% of patients and can be associated with TR [12]. TS also may be secondary to carcinoid syndrome, intracardiac tumors or infective endocarditis. Clinically, TS is not well tolerated. Impairment to RV filling may produce symptoms of right-sided heart failure [11, 12]. Carcinoid valve lesions manifest as fibrous white plaques located on the valvular and mural endocardium. The valve leaflets are thickened, rigid, and reduced in area. Fibrous tissue

proliferation is present on the atrial and ventricular surfaces of the valve structure [13]. Surgical reports have recommended TV replacement (TVR) with a mechanical prosthesis in patients with carcinoid syndrome based on the assumed damage to bioprosthetic valves from vasoactive substances, but this has not been well established [14-16]. Mukhopadhyay et al. [17] reported a case producing features of TS because of an unusual presentation of primary antiphospholipid antibody syndrome presenting as intracardiac thrombus over the tricuspid valve. The ACC/AHA guidelines recommend TV surgery for patients with severe TS at the time of operation for left-sided valve disease (Class I, Level of Evidence C) and for symptomatic patients with severe TS (Class I, Level of Evidence C) [5].

Rheumatic Tricuspid Valve Disease

Rheumatic heart disease is still common in developing countries. Although the TV usually is not involved in rheumatic heart disease, its involvement is associated with mitral and/or aortic valve dysfunction and the TV is frequently both stenotic and regurgitant [18]. The TV will have diffusely thickened leaflets with or without fusion of commissures. Chordae tendinae will be thickened and shortened. Deformity of the valve tissue can lead to TS with coexisting TR.

ATRIAL FIBRILLATION IN PATIENTS WITH TRICUSPID VALVE DISEASE

Atrial fibrillation (AF) is a common complication in advanced valvular heart disease. Isolated severe TR is a rare disease, and the literature describing the natural history and management of this condition is sparse. The Framingham Heart Study found the prevalence of moderate or greater TR to be 0.28% in adult men and 1.44% in adult women [19]. However, the clinical impact of TR is very significant. Severe TR is associated with markedly reduced survival ($38 \pm 7\%$ for severe TR vs. $70 \pm 6\%$ for less than severe TR at 10 years) [20]. As a result, the 2014 ACC/AHA guidelines state that surgical repair of symptomatic severe primary TR is reasonable (Class IIa recommendation), although this recommendation is not supported by randomized controlled trials or robust clinical data (level of evidence C) [5].

A history of AF is common in patients with both isolated primary and functional TR, with a prevalence of 40% and 44%, respectively [20, 21]. As many as 25% of patients with severe TR are in AF at the time of diagnosis, and primary TR due to a flail leaflet is associated with a 2.8% annual incidence of new AF [21]. AF in patients with TR is associated with a significant excess risk of mortality (hazard ratio 1.77, CI 1.14-2.79, $p = 0.01$) [20]. As a result, it is reasonable to treat AF at the time of TV surgery. However, evidence for a survival advantage in patients undergoing AF ablation at the time of surgery is lacking.

Surgical Ablation for AF Concomitant to Tricuspid Valve Surgery

For patients undergoing cardiac surgery, more than 50% of AF surgery is performed concomitant with MV surgery. AF is associated with reduced survival and increased risk of stroke [22-24]. The Cox-Maze procedure was originally designed as a concomitant procedure by Dr. James Cox for the treatment of AF in patients undergoing MV surgery. However, the complexity of the operation and the time required to complete the procedure limited its clinical application for many years to patients with lone AF. The ablation-assisted Cox-Maze IV procedure (CMIV) was introduced in 2002. The CMIV simplified the procedure by replacing most of the atrial incisions of the Cox-Maze lesion set with linear lines of ablation, making the operation technically easier and faster to perform [25]. Currently, more than 80% of these procedures are completed with the assistance of ablation technology, and more than 95% are performed as concomitant operations to other cardiac surgical procedures [22]. Our group has demonstrated that, for low-risk patients, the addition of a concomitant CMIV procedure does not increase the operative risk greater than that expected for MV surgery alone and produces a high degree of freedom from AF and antiarrhythmic medications in these patients [26].

Indications for Surgical Ablation of Atrial Fibrillation

The indications for catheter and surgical ablation of AF are detailed in the 2012 Expert Consensus Statement of the Heart Rhythm Society Task Force on Catheter and Surgical Ablation of Atrial Fibrillation [27]. Concomitant surgical ablation of AF at the time of other cardiac surgical procedures is indicated for 1) all symptomatic AF patients undergoing other cardiac surgical procedures, regardless of prior treatment with antiarrhythmic medications, and 2) selected asymptomatic AF patients undergoing cardiac surgery in which the ablation can be performed with minimal additional risk.

CRITERIA FOR USE OF A MINIMALLY INVASIVE APPROACH

The selection of a minimally invasive as opposed to a traditional surgical approach should be based on the presence of concomitant cardiac pathology, patient-specific anatomy, and the experience of the operating surgeon. Our practice is to perform a full biatrial Cox-Maze IV procedure through a minimally invasive right thoracotomy approach in patients undergoing concomitant mitral or tricuspid valve surgery. The Cox-Maze IV procedure is performed through a standard median sternotomy when combined with other concomitant procedures such as aortic valve replacement and coronary artery bypass grafting (CABG). Median sternotomy is reserved for patients with contraindications to a minimally invasive right mini-thoracotomy approach such as peripheral vascular disease that precludes femoral cannulation for cardiopulmonary bypass (CPB), a history of previous right thoracotomy, severe left ventricular dysfunction, or chest wall deformities.

TRICUSPID VALVE REPAIR TECHNIQUES AND APPROACHES

The principles of therapy for secondary TR include elimination of increased afterload to the RV (by correction of left-sided heart disease and restoration of left ventricular function) and correction of tricuspid annular dilatation, by tricuspid valve annuloplasty (suture or prosthetic ring annuloplasty). With rigid or semi-rigid prosthetic ring annuloplasty, the annulus is permanently fixed in a systolic position and the physiologic shape of the tricuspid valve is restored [28]. Flexible rings also may be used, but even though they decrease the size of tricuspid annulus, they are unable to restore its normal morphology. If severe valve tethering is present, the use of an adjunctive procedure such as enlargement of the anterior leaflet or TVR should be considered.

After an initial right atriotomy, the tricuspid valve should be inspected for asymmetrical dilatation in the posterior region and fixation of the septal annulus to the fibrous skeleton of the heart. In 1972, DeVega introduced a partial annuloplasty in the posterior region of annulus that consisted of a double continuous suture starting from the anteroseptal commissure and ending at the posteroseptal commissure [29]. The annuloplasty was nearly circumferential and ended in the region of the atrioventricular node. When TR meets criteria for repair, the current technique of choice is ring annuloplasty although suture annuloplasty is still performed by some surgeons. This technique utilizes a structured band to reduce the antero-posterior diameter of the tricuspid annulus. The ring is sized to the septal leaflet and carefully secured to avoid injury to the conduction system. Ring types most commonly used are those described by Carpentier-Edwards and colleagues (Carpentier-Edwards semirigid ring, MC3 3D ring, Carpentier-Edwards physio tricuspid ring, Edwards LifeSciences, Irvine, CA [28]; Duran and Ubago (Duran flexible ring, Medtronic, Dublin, Ireland)[30]; McCarthy and Cosgrove (Cosgrove-Edwards flexible band, Edwards LifeSciences, Irvine, CA) [31]; and Kshetry and Kanda (Carbomedics Annuloflex ring, Sulzer Carbomedics, Inc., Austin, TX) [32].

Tricuspid valve ring annuloplasty improves long term survival, event-free survival, and survival free of recurrent TR compared with De Vega suture annuloplasty in a large series by Tang et al. of 702 patients who underwent TVr [33]. They also showed that TV ring annuloplasty was an independent predictor of long-term survival [33]. Among the different types of prosthetic rings, semi-rigid or rigid rings (either standard or 3D) have been associated with the best results and the lowest rate of recurrent TR. In two large series published by groups at Cleveland Clinic, the degree of postoperative grade 3+ or 4+ TR remained stable over time with the Carpentier-Edwards ring (12% at 5 years and 17% at 8 years) and rose constantly with De Vega procedure, with an overall rate of 24% at 5 years and 33% at 8 years [33, 34]. Evidence for the utility of TV ring annuloplasty during MV surgery and the tricuspid annulus diameter as a guide for TVr comes from a study by Dreyfus et al. [9] of 311 patients who underwent MVr. The TV annulus was measured intraoperatively with a ruler, from the anteroseptal commissure to the anteroposterior commissure. The TVr with a Carpentier-Edwards ring was performed regardless of the degree of TR if the tricuspid valve annulus diameter was >7 cm. TVr was performed in 48% of the patients, despite the fact that 88% had mild TR (grade <1 TR).

Tricuspid valve annuloplasty has been shown to add little time and complexity to MV surgery and has been associated with few additional complications [9, 33, 35]. In functional

TV disease, Singh et al. [35] showed that repair is better than replacement. If the TV needs replacement, the surgeon should excise or imbricate the anterior and posterior leaflets in order to retain the subvalvular apparatus. Sutures should be placed in the septal leaflet proper to avoid the conduction system. Bioprosthetic valves degenerate with time, and mechanical valves in the tricuspid position tend to thrombose. They reported a 5-fold risk of early death during the perioperative period with TVR, which also was an independent predictor of poor survival after surgery. Chang et al. [36] reported a large series of 360 patients with severe TR who underwent TVR (27%) or TVr (73%) [36]. Their study showed no difference in early mortality between the two approaches (TVR:TVr, 3.1%:3.4%, $p = 0.877$). Ten-year overall survival (TVR:TVr, 72%:70%, $p = 0.532$) and ten-year freedom from cardiac death (TVR:TVr, 76%:77%, $p = 0.715$) were not significantly different between the two groups. They concluded that TVR had acceptable early and late outcomes in patients with severe TR. TVR can be considered as a valid option with acceptable clinical outcomes in patients who are not suitable candidates for TVr [36]. Mechanical valve replacement may require permanent epicardial pacing lead placement later because percutaneous leads cannot be placed through a mechanical valve. In the Chang series, a mechanical prosthesis was used in 69 patients (71%) and a bioprosthesis in 28 patients (29%). They preferred a mechanical prosthesis when the patients had a previously implanted mechanical prosthesis in the left heart. A bioprosthetic valve was chosen when the patient life expectancy was less than 15 years [36].

MINIMALLY INVASIVE TRICUSPID VALVE REPAIR RESULTS

The increasing popularity of minimally invasive procedures has affected every surgical specialty. Advancements in cardiac imaging and special surgical instrumentation have enabled cardiac surgeons to perform complex cardiac surgery through small incisions. Minimally invasive approaches to the MV and the aortic valve either through a right mini-thoracotomy or a partial sternotomy have been well described. In addition to improving cosmesis, minimally invasive mitral valve surgery was pioneered with the intent of reducing morbidity, postoperative pain, postoperative blood loss, hospital length of stay, and the time required for patients to return to normal activity. However, there is a paucity of studies regarding minimally invasive TV operations. Kypson et al. [37] reported 33 consecutive patients who underwent TVr or TVR performed via a right mini-thoracotomy with 6% perioperative mortality and 3% conversion to median sternotomy. The largest reported series of 141 patients who underwent a TV operation via mini-thoracotomy was at Duke University between 1997 and June 2008 and revealed a 30 day mortality rate of 2.1%, a rate of conversion to median sternotomy of 3%, and a mean CPB time of 216 minutes [38].

Minimally invasive right mini-thoracotomy is an alternative approach for use in reoperative cases. Reoperative median sternotomy carries the potential for two different iatrogenic insults to the RV: 1) traumatic injury during surgical dissection of the heart, and 2) irreversible distention of an extremely thin and chronically volume overloaded RV, resulting in continuing right heart failure after removal of adherent scar tissue. A right lateral minithoracotomy approach in patients requiring reoperative RV surgery is the technique of choice at our institution. Pfannmuller et al. [39] reported the results of 48 patients who

underwent isolated TV operations after previous cardiac operations with minimally invasive access through a right lateral thoracotomy and showed a 30 day mortality rate of 0% in patients undergoing elective surgery and an early mortality rate of 4.2% for all patients. Five-year survival for patients after elective reoperative TV repair via minimally invasive access was $72.2\% \pm 10.0\%$, and five-year freedom from tricuspid valve-related reoperation was $88.1\% \pm 6.7\%$.

THE COX-MAZE IV PROCEDURE: SURGICAL TECHNIQUE

At our institution, bipolar radiofrequency energy and cryoablation have been used to replace most of the surgical incisions of the cut-and-sew Cox-Maze III procedure. Our current radiofrequency ablation-assisted procedure, termed the Cox-Maze IV, was introduced in 2002 and replicates the lesion set of the Cox-Maze III [40]. Our clinical results have shown that this modified procedure achieves the high success rate of the Cox-Maze III procedure while significantly reducing operative time and lowering complication rates [41-42].

When valvular heart disease is limited to the tricuspid position, it is reasonable in highly selected cases, particularly those with congenital heart disease, to use only incisions on the right-side for the Maze operation. Avoiding left atrial (LA) manipulation shortens CPB time and aortic cross-clamp (AoX) time. We usually perform the right atrial (RA) lesion set on the beating heart. However, in most patients who do not have congenital heart disease, we tend to perform a biatrial lesion set, since most patients have associated LA enlargement. The use of improved preoperative diagnostic modalities in the future may better inform this decision.

If a median sternotomy is performed, the Cox-Maze procedure is performed as shown in Figure 1 [40]. The superior vena cava (SVC) and inferior vena cava (IVC) are dissected and bicaval cannulation is performed. Both sets of pulmonary veins are dissected and encircled with umbilical tape. A bipolar radiofrequency clamp is used to isolate a cuff of atrial tissue surrounding the right and then the left pulmonary veins. The clamp is not released until an ablation time of less than ten seconds is achieved. This usually takes two-three ablations. We usually perform three sets of ablations in this manner for each ablation line. Pacing from the pulmonary veins while monitoring the surface electrocardiogram is used to confirm exit block. Subsequently, the RA lesion set is performed as has been described previously [43]. If LA lesions are to be performed, they are performed on the arrested heart with an AoX in place (Figure 1B). The left atrium (LA) is dissected and opened in the interatrial groove. The bipolar radiofrequency clamp is used to make “roof” and “floor” lesions from the atriotomy to the left superior and inferior pulmonary veins, respectively. The clamp is also used to create an ablation from the inferior margin of the atriotomy toward the mitral annulus, taking care to avoid the circumflex coronary artery. As the bipolar clamp cannot reach the annulus itself, a bell-shaped cryoprobe is used to make an endocardial lesion to the mitral annulus and an epicardial lesion over the coronary sinus. The left atrial appendage (LAA) is managed by oversewing its orifice in two layers from an endocardial approach. If a MV procedure is performed, it is performed at this time. The LA is then closed with a running polypropylene suture. The patient is weaned from CPB and closed in standard fashion.

Figure 1. Standard right (A) and left (B) atrial lesion sets utilized for the Cox-Maze IV procedure. In the right atrium (A), radiofrequency ablation lines (white lines) extend from superior vena cava to inferior vena cava and along the right atrial free wall down to tricuspid valve annulus. In the left atrium (B), all ablation lines are performed with a bipolar radiofrequency clamp except for an endocardial cryoablation at the mitral annulus and an epicardial cryoablation over the coronary sinus (From Weimar T, Bailey MS, Watanabe Y, et al. The Cox-maze IV procedure for lone atrial fibrillation: a single center experience in 100 consecutive patients. *J Interv Card Electrophysiol.* 2011;31:47-54).

For the minimally invasive approach, exposure and access are obtained as follows. The patient is positioned supine, and general anesthesia is induced. A double-lumen endotracheal tube is used. Transesophageal echocardiography (TEE) is used to confirm the diagnosis of TR, examine for other pathology, and rule out a thrombus in the LAA. The right chest is elevated to a 30-45° angle. The patient is prepped and draped in sterile fashion. Femoral cannulation for CPB is obtained. The guidewires and cannulae are advanced into the descending thoracic aorta and the right atrium (RA) using TEE visualization. A 5-6 cm mini-thoracotomy is performed over the fourth intercostal space (ICS) lateral to the nipple in the mid-axillary line in men; a submammary incision is used in women (Figure 2). A small segment of the posterior fifth rib is removed, and a soft tissue retractor is used to improve visualization. No rib spreading is performed. A Blake drain is placed through the lateral chest wall and positioned in the posterior right pleural space. Carbon dioxide is infused through this drain to prevent air embolism. After the pericardium is opened, a thoracoscope is placed through a port in the fifth ICS near the posterior axillary line.

If a biatrial Cox-Maze procedure is planned, the oblique and transverse sinuses and the inter-atrial septum are mobilized. The right pulmonary veins are dissected and encircled with umbilical tape. Pacing thresholds are obtained. The right pulmonary veins are isolated using three sequential sets of ablations of a cuff of atrial tissue surrounding the veins with a bipolar radiofrequency device. Exit block is tested by pacing the pulmonary veins at two times the previously documented pacing threshold while monitoring the electrocardiogram for capture. Ablation is continued until exit block is documented.

Figure 2. Patient positioning for the minimally invasive Cox-Maze IV procedure, performed through a 5–6 cm right mini- thoracotomy in the inframammary fold. A 2-cm subinguinal incision is used for femoral vessel cannulation for cardiopulmonary bypass (Robertson et al., *Annals of Cardiothoracic Surgery*, used with permission).

The RA lesion set is performed on the beating heart (Figure 2A). Although we usually perform the RA lesions through purse-string sutures, in the case of tricuspid annuloplasty a vertical atriotomy is made from just above the inter-atrial septum midway between the SVC and IVC and extending toward the AV groove near the free margin of the RV. The femoral venous cannula is withdrawn into the IVC under direct vision (Figure 3). A 20 french venous cannula is placed through a stab wound in the lateral chest wall and positioned into the SVC under direct vision. Umbilical tapes or direct clamping of the proximal cava can be used if there is venous blood flow into the RA obscuring the operative field, however this is usually not necessary as long as vacuum assist is used to augment venous drainage. The remaining lesions are then performed as described above. A bipolar radiofrequency clamp is placed through the atriotomy and is used to create two lesions: one up onto the SVC (Figure 4) and one down onto the IVC. The device is fired three times with slight changes in position for each lesion. A reusable linear cryoprobe or flexible disposable cryoprobe is placed endocardially from the upper end of the atriotomy down to the tricuspid annulus at the 1 o'clock position (Figure 5). This cryoablation is performed by freezing to -60°C for three minutes, as are all subsequent cryoablations. A purse-string placed at the base of the right atrial appendage (RAA). The RA is opened with a stab incision, and the bipolar radiofrequency clamp is used to make a lesion toward the SVC at least 2 cm away from the previous SVC lesion, and down the aortic side of the RAA to avoid the region of the SA node. An endocardial cryoablation is then made from the base of the RAA down to the tricuspid annulus at the 11 o'clock position with the linear or disposable cryoprobe. A ring tricuspid valve annuloplasty is then performed as described above, and the final result is shown in Figure 6. The atrium is closed with a running polypropylene suture.

If LA lesions are to be performed, they are performed on the arrested heart as shown in the schematic (Figure 7). The LA is dissected and opened in the interatrial groove. Exposure is obtained using an atrial lift retractor. The bipolar radiofrequency clamp is used to make “roof” and “floor” lesions from the atriotomy to the left superior and inferior pulmonary veins, respectively. The clamp is also used to create an ablation from the inferior margin of the atriotomy toward the mitral annulus, taking care to avoid the circumflex coronary artery. As the bipolar clamp cannot reach the annulus itself, cryoprobes are used to make an endocardial lesion to the mitral annulus and an epicardial lesion over the coronary sinus. The LA “box” is completed by using a T-shaped cryoprobe to create lesions behind the left pulmonary veins, along the lateral ridge, connecting the roof and floor lesions. The LAA is managed by oversewing its orifice in two layers from an endocardial approach. If a mitral valve procedure is performed, it is performed at this time. The LA is then closed with a running polypropylene suture. The patient is weaned from CPB and closed in standard fashion.

Figure 3. Right atrial cannulation and atriotomy. SVC cannula and cardioplegia cannula are visualized to the left. Transfemoral IVC cannula is visible within the atrium.

THE COX-MAZE IV PROCEDURE: SURGICAL RESULTS

Our results from patients who underwent the Cox-Maze IV procedure have been encouraging. In a prospective, single-center trial from our institution, 91% of patients at 6-month follow-up were free from AF [25]. The Cox-Maze IV procedure significantly shortened the mean AoX times for a stand-alone Cox-Maze from 93 ± 34 minutes for the cut-and-sew Cox-Maze III to 47 ± 26 minutes for the Cox-Maze IV ($p < 0.001$) [25]. A propensity analysis showed that there was no significant difference in freedom from AF at 3, 6, or 12 months postoperatively between the appropriately matched Cox-Maze III and IV groups [42]. A more recent prospective cohort study from our institution in 100 consecutive patients who underwent a stand-alone Cox-Maze IV procedure demonstrated postoperative freedom from AF of 93%, 90%, and 90% at 6, 12, and 24 months, respectively [40]. A report of over two decades of experience at our institution with both the Cox-Maze III and Cox-Maze IV procedures showed no difference in freedom from AF and a significantly decreased major complication rate between the two procedures [44].

The Cox-Maze IV procedure worked as well in patients with paroxysmal AF as it did for patients with longstanding persistent AF. Our most recent report of Cox-Maze IV data reviewed 576 consecutive patients who underwent this procedure between January 2002 and September 2014 [45]. All patients were followed with ECG, pacemaker interrogation or 24-hour Holter monitoring. Our 12-month rate of freedom from AF was 93%, with 85% of those patients also off all antiarrhythmic drugs, while our 5-year freedom from AF was 78%, with 66% of those patients also off all antiarrhythmic drugs. Comparisons of patients with paroxysmal versus non-paroxysmal AF on and off antiarrhythmic drugs were not significantly different at any time point [43]. Other groups have had similar results [46].

The Cox-Maze procedure has also been successful in reducing the incidence of stroke. In patients undergoing the Cox-Maze procedure, the preoperative incidence of neurological events has been high. In a report from our institution, 57 of 433 patients (13%) had experienced a preoperative neurological event. Despite this, there were only six neurological events during long-term follow-up (mean, 6.6 ± 5.0 years) in this cohort. The long-term stroke rate after the Cox-Maze procedure has been 0.2% per year despite the fact that the majority of patients had discontinued their anticoagulation therapy [47].

The Cox-Maze procedure is most commonly performed as a concomitant procedure [22]. Previous studies from our institution and others have documented high rates of restoration of sinus rhythm without increasing morbidity following concomitant procedures, including CABG, MV surgery, TV surgery, and aortic valve surgery [28, 48-56].

MINIMALLY INVASIVE COX-MAZE IV PROCEDURE AND TRICUSPID ANNULOPLASTY RESULTS

The published literature regarding the use of minimally invasive surgical ablation in the isolated TV disease population is sparse. Schaff and colleagues [57] at the Mayo Clinic published a series of 42 patients undergoing TVr or TVR with right-sided Cox-Maze procedure, and there were no instances of complete heart block or sinus node dysfunction requiring permanent pacemaker implantation. Follow-up of the first 18 patients showed that

all had NYHA class I symptoms. Early postoperative atrial arrhythmias occurred in 3 of 18 patients, and they were managed successfully with medication [57]. Late outcomes in the Mayo Clinic Cox-Maze series were similar to those reported by other centers, and the authors did not perform subgroup analysis of late outcomes in patients undergoing Cox-Maze and tricuspid valve procedures only.

We reviewed outcomes of minimally invasive TVr with concomitant Cox-Maze IV procedure at our institution. All patients gave informed consent for inclusion in our institutional database under a protocol approved by the Institutional Review Board. From July 2005 to August 2015, TVr or TVR with concomitant Cox-Maze IV procedure was performed in eight patients with severe TR and AF. Three patients had a history of prior cardiac surgery (orthotopic heart transplant, thoracic aortic aneurysm repair, CABG). Two patients received bioprosthetic TVR; the remainder were treated with ring annuloplasty. Four patients underwent concomitant MVR, one underwent concomitant MVR, and one underwent patch closure of a secundum atrial septal defect. In two of the three patients who underwent TV surgery alone, only the RA Cox-Maze lesions were performed; the remaining patients received the biatrial lesion set.

Postoperative outcomes were as to be expected in this high-risk group of patients. There was one operative mortality, a reoperative patient who underwent minimally invasive MVR, TVr and Cox-Maze IV. This patient developed pneumonia and respiratory failure and ultimately succumbed to recurrent episodes of ventricular tachycardia. Three patients required postoperative pacemakers, and two patients required reexploration for groin seromas. There were no other major complications. Six patients were alive at one year, and 5/6 were free from atrial tachyarrhythmias, all of whom had discontinued taking antiarrhythmic drugs. The one patient with five-year follow-up was free from atrial tachyarrhythmias and antiarrhythmic drugs and is alive at eleven years postoperatively. The Kaplan-Meier estimate of the median survival was 3.4 years.

CONCLUSION

The surgical treatment of secondary TR is still an object of debate. Severe TR should always be corrected at the time of left-sided heart surgery. In cases of less than severe regurgitation, the diameter of the tricuspid annulus (rather than the degree of regurgitation) should be the criterion to indicate the need of concomitant TVr. The minimally invasive approach has been shown to be safe, feasible, and reproducible in TV operations. It ensures low perioperative morbidity and mortality and low rates of TR recurrence. It also has similar benefits in reoperative procedures. However, most series in the literature are small and retrospective.

The right mini-thoracotomy Cox-Maze IV procedure is one of the only minimally invasive techniques that fully replicates the complete lesion set of the original Cox-Maze procedure. Long term outcomes of minimally invasive surgical ablation at our institution have matched those achieved with the standard median sternotomy approach [58]. The right mini-thoracotomy approach is familiar to many cardiac surgeons who perform minimally invasive MV and TV surgery and should therefore be generalizable to cardiac surgeons at large in the

future. A combination of these approaches to treat the patient with isolated TV disease and AF is feasible, but further prospective studies should be performed.

Chapter 426

CONTEMPORARY RESULTS IN MINIMALLY INVASIVE MITRAL VALVE SURGERY

Daniel Pereda*, MD and José L. Pomar, MD, PhD

Hospital Clínic, Department of Cardiovascular Surgery,
University of Barcelona. Barcelona, Spain

ABSTRACT

Minimally invasive mitral valve surgery (MIMVS) has been increasingly performed over the last 20 years, as growing support of evidence indicates that it provides excellent results, comparable to conventional mitral surgery performed through a full sternotomy. As our knowledge and expertise increases, MIMVS can now be offered to the vast majority of patients requiring a surgical intervention on their mitral valve, providing a better cosmetic result and a quicker recovery, with a similar risk profile and without a tradeoff in repair rate and durability. In fact, there is currently data supporting its feasibility and its role on many traditionally difficult subsets of indications such as: elderly patients, reoperations, endocarditis or Barlow's disease. In the present chapter we will review some of the most recent evidence on the current results of MIMVS.

Keywords: mitral valve surgery, postoperative complications, mortality, minimally invasive surgical procedures, treatment outcome

INTRODUCTION

Mitral valve (MV) surgery through a full sternotomy has been established over the years as the gold standard treatment for patients with all kinds of MV pathology requiring valve repair or replacement. Since the first cases performed in the mid-90's, many efforts have been made and many advances have been accomplished in the direction of reducing surgical aggression through minimally invasive approaches to repair or replace the mitral valve, while

* Corresponding Author's Email: dpereda@clinic.cat.

trying to maintain the excellent results and safety profile of conventional mitral surgery. The term minimally invasive mitral valve surgery (MIMVS) does not define a specific approach and many variations have been included under this term. These variations include surgical approaches other than a full median sternotomy such as partial upper or lower sternotomies or right/left small thoracotomies. Additionally, these operations can be performed with different degrees of thoracoscopic video-assistance and specifically designed instrumentation, including robotic telemanipulation. This surgical heterogeneity together with several different adaptations of cardiopulmonary bypass (CPB) and myocardial protection strategies, add to the difficulty in analyzing and comparing historical and current results of minimally invasive mitral valve repair (MIMVr).

Early and long-term results of MIMVS have improved over the years complemented by the advance in our knowledge of MV pathology and surgical repair, but also by a continuous improvement in other fields like: intraoperative imaging, instrument design, endoscopic high-definition video assistance, CPB, and more recently with high-definition 3D visualization or robotic telemanipulation. Currently, minimally invasive approaches to treat the MV are preferred over conventional surgery in many high-volume mitral valve surgery centers throughout the world, particularly in Europe. In these hospitals, most patients are now offered a minimally invasive approach to repair or replace their MV with excellent results and regardless of mitral disease complexity or patient risk profile. Some decisive factors responsible for this continuous improvement in MIMVS are: better preoperative evaluation of the patients, continuous refinement of specifically-designed cannulae for extracorporeal circulation (allowing a smoother introduction and significantly increased drainage with smaller outer diameters), routine intrathoracic CO₂ insufflation, alternative ways of transthoracic aortic cross-clamping and re-engineered intra-aortic balloon occluders, improvement in myocardial protection protocols, the addition of techniques for atrial fibrillation ablation and increasing physician's skills as the result of the commitment of many surgeons to advanced MV repair (MVr) techniques. Very importantly, we have to acknowledge the perseverance of some pioneers, believers of this *minimally invasive philosophy*, and their contribution in developing educational programs, which have allowed the progression –although slow- of MIMVr within our surgical community.

MIMVr is undeniably appealing to both patients and physicians, holding the promise of improved cosmetic results, a shorter hospital stay, faster return to normal activities and less postoperative pain and blood loss, while maintaining the same high-quality results of conventional MV surgery through a full sternotomy. In this chapter, we will review the most recent evidence supporting MIMVr, particularly for degenerative mitral valve disease. We will pay special attention to safety and long-term durability of MVr, two of the most inquired aspects of MIMVS since the beginning of these operations. The main concerns that have been raised against these operations are a supposed higher rate of neurological complications and aortic dissection and a lower rate of MVr, with more valves being replaced. Detractors of MIMVr also claim it is more demanding technically and requires a long learning curve before achieving good results; while these statements may be true, and in fact the second has been beautifully described by the Leipzig group recently [1], current published evidence report excellent outcomes in terms of postoperative neurological complications, rate of successful repair and repair durability, that match in every aspect those of some of the best modern series of conventional mitral valve repair through a full sternotomy.

PERIOPERATIVE OUTCOMES AND NEUROLOGICAL COMPLICATIONS

Since the first developments on minimally invasive cardiac surgery in the early 90's, a strong debate started between its supporters and detractors. The discussion focused on its foreseen benefits in terms of decreased surgical trauma, improved patient recovery and shorter hospital stay, and the supposedly increased risks of neurological complications, worse rates of mitral repair, decreased repair durability and its greater technical complexity requiring a steep learning curve. This debate has been an intense and enduring one, and at times has even left the academic medical arena and has made it to the general public through the mass media [2].

One of the most controversial and criticized aspects of MIMVS has always been the possibility of an increased risk of postoperative stroke and neurological complications. Several factors have been pointed as playing a role in this increased risk, including the use of retrograde femoral perfusion, difficult cardiac deairing, embolization of subcutaneous fat debris from the port incisions and endovascular manipulation of the thoracic aorta with the use of endoaortic balloon occlusion (Figure 1).

With our current knowledge most of this risk has been reduced with better preoperative evaluation and patient selection, identifying those patients at increased risk of neurological complications such as older patients, patients with peripheral or carotid vascular disease and patients with a heavy burden of risk factors for atherosclerosis: smokers, diabetes mellitus, previous history of myocardial infarction or stroke. A focused medical anamnesis and preoperative clinical examination may reveal most of these risk factors and, for those patients at increased risk, a preoperative vascular imaging evaluation with MRI or CT can be obtained to help in the selection of the best surgical strategy to maximize safety (i.e., choosing axillary cannulation or direct aortic cannulation in patients with abdominal aortic aneurysms or with a diseased bilateral iliac–femoral axis). Another area of improvement has been the widespread adoption of CO₂ insufflation. In its early experience, the Leipzig group reported an incidence of postoperative confusion of 18% that greatly improved after CO₂ insufflation was routinely performed [3]. In a study by Schneider et al. using trans-cranial Doppler in MIMVS (using endoaortic balloon occlusion and CO₂ insufflation) as compared to conventional surgery, no differences were found in the cerebral microembolic rate [4].

A meta-analysis published in 2008 by Modi et al. [5], compared the combined data from 11 case-control and 1 randomized clinical trial published between 1998 and 2005 (with some patients operated on as early as 1990). None of the individual studies included or the analysis of the pooled data (1641 patients OR = 0.46; 95%CI = 0.15-1.42; p = 0.18) showed a significant difference in mortality between MIMVS and conventional surgery. Regarding the risk of postoperative stroke, there was no significant difference in neurological events on meta-analysis of 6 eligible studies (1801 patients. OR = 0.66; 95%CI = 0.23-1.93; p = 0.45). A significant difference favoring MIMVS was found in the rate of reoperation for bleeding (1553 patients. OR = 0.56; 95%CI = 0.35-0.9; p = 0.02). In this meta-analysis, when comparing the largest cohort series published on MIMVS to the Society of Thoracic Surgeons (STS) database data, mortality did not differ from that reported on the STS database for both MVr (2173 patients) and replacement (MVR)(979 patients): 1.1% in MVr and 4.9% in MVR vs. 1.5% in MVr and 5.5% in MVR, respectively. The incidence of neurological complications was also lower: 1.6% in MVr (1226 patients) and 2.3% in MVR (778 patients) vs. 1.9% in MVr and 3.2% in MVR.

Figure 1. A: Intra-aortic balloon occlusion device (Edwards Intraclute, Edward Lifesciences, CA, USA). B: Transthoracic aortic clamp.

A more recent meta-analysis was published in 2011 by Cheng et al. [6]. It was limited to MIMVS performed through right minithoracotomy or a parasternal incision, thus excluding partial sternotomies. This meta-analysis included a larger pooled population from 35 published studies (18 with predominant use of endo-aortic balloon occlusion, 13 with predominant transthoracic aortic clamping and 4 using similarly both techniques). Perioperative mortality was similar with MIMVS and conventional surgery (13066 patients in 20 studies: 1.2% vs. 1.5% respectively; $RR = 1.03$, 95% $CI = 0.75-1.42$), as were long-term need for valvular reintervention and survival. In one hand, MIMVS was found to provide better results in terms of: less blood loss and transfusions, atrial fibrillation, chest wound infection, ventilation time, ICU (-0.8 days in average) and hospital (-2 days in average) length of stay, and reduced time to return to normal activities. On the other hand, MIMVS was found to be associated with an increased risk of stroke (12655 patients in 11 studies: 2.1% vs. 1.2%, $RR = 1.79$, 95% $CI = 1.35-2.38$), aortic dissection (0.2% vs. 0%), phrenic nerve palsy (3% vs. 0%), and groin infections (2% vs. 0%). MIMVS also required a longer duration of CPB (+33 min in average) and aortic cross-clamp (+21 min in average), with an overall longer procedural time (+0.8 hours in average).

These two meta-analyses of comparative studies together with large series published more recently represent the best evidence available on MIMVS. Only two small underpowered RCT have been conducted so far and were not able to find significant differences [7, 8]. The vast majority of comparative studies consist on small cohorts of unmatched patients with retrospective data collection and without any information on mid or long-term follow-up. Large institutional series provide longer follow-up data but lack a control group for comparisons. In this scenario, it is extremely difficult to obtain any solid conclusions regarding these infrequent -but critical- outcomes such as mortality and risk of stroke. Very large randomized trials would be necessary to have enough statistical power to elucidate these issues. As we all know, such trials are extremely difficult (if not impossible) to perform in cardiac surgery, so we will probably not be seeing such studies coming in our horizon on the near future. Despite these limitations it seems that, at least in high-volume centers of expertise, MIMVS can provide similar quality outcomes as the gold standard operation performed through a median sternotomy, with a better cosmetic result, increased patient satisfaction, less postoperative pain and blood loss, and a shorter length of hospitalization.

POSTOPERATIVE PAIN AND PATIENT RECOVERY

From the list of potential benefits of MIMVS, besides an irrefutable superior cosmetic result, a faster return to normal activities and less postoperative pain rank amongst the most consistently reported. In a study by Walther et al. [9], postoperative pain was similar after a right minithoracotomy as compared with a median sternotomy during the first two days after the operation and from the third day onwards the difference widened in favor of MIMVS. Glower et al. [10] reported decreased postoperative pain and a significantly faster return to normal activities after MIMVS (4 ± 2 weeks vs. 9 ± 1 week; $p = 0.01$). Interesting is the fact that in two different studies [11, 12], patients reoperated on with MIMVS after a previous full sternotomy reported that they felt their second procedure was less painful and had a faster recovery.

LENGTH OF HOSPITAL STAY AND COST

It is believed that patients recover faster from MIMVS than from a conventional operation through a full sternotomy and in fact, one of the most consistently found results in comparative studies is the reduction on the time patients spend in the ICU and in the hospital. In the 2008 meta-analysis by Modi et al. [5], the pooled analysis showed a trend towards a shorter postoperative stay after MIMVS (350 patients. OR = -0.73; 95%CI = -1.52 – 0.05; $p = 0.07$). These patients were more often discharged home, with less patients being sent to post-hospital rehabilitation facilities as compared with conventional surgery (9% vs. 33%) [13, 14]. The more recent meta-analysis by Cheng et al. [6] reported that duration of ICU (10435 patients in 18 studies: 1.6 vs. 2.4 days; $p < 0.0001$) and hospital stay (12249 patients in 26 studies: 6.9 vs. 8.9 days; $p < 0.00001$) were significantly reduced with MIMVS. In this study,

the duration of mechanical ventilation was also found to be significantly reduced after MIMVS (11434 patients in 18 studies: 12.6 vs. 19.9 hours; $p = 0.002$).

In terms of hospital costs there is little information available, since studies looking into this are scarce. A study from the United States reported that MIMVS reduced hospital costs (-\$9160) [15]. However, operating room charges in this study were not time-dependent and this may have had an impact on the results, because the operating room time for MIMVS was 1.6 hours longer. Another study from Slovenia also reported that MIMVS had lower mean hospital cost [16], but none of these studies provided a comprehensive cost-effectiveness analysis. A more recent study by the Mayo Clinic group [17], compared costs in 370 propensity-matched pairs who underwent robotic or conventional MVr before and after implementing a program of improvement. Median length of stay for patients undergoing open repair was unchanged at 5.3 days before and after the program implementation, but was lower for robotic patients (3.5 vs. 3.4 days; $p = 0.003$). Despite the high costs of robotic technology, after the implementation of the program hospital costs became similar to that of open repair (\$30606 vs. \$31310; $p = 0.876$).

MITRAL VALVE REPAIR RATE AND REPAIR DURABILITY

A criticism that has been raised against MIMVr is that, due to its technical difficulty, more repairable valves are not spared and are replaced instead. In this same line of thought, it has been argued that repair results may be not as good as with open surgery, translating into a worse repair durability, with a higher incidence of recurrent mitral regurgitation (MR) on follow-up. MVr represents an excellent scenario for minimally invasive approaches, where the surgeon can get the most of the high-definition intracardiac video images, allowing an unparalleled exposure and visualization of the MV and the subvalvular apparatus. These advantages together with our current level of knowledge on MVr, particularly for the myxomatous mitral disease, have made results of MIMVr in high expertise mitral centers in terms of repair rate as good as those of conventional surgery in some of the best MVr series published [18-20].

In a recently published study, the Mayo Clinic group reported on their midterm results after robotic MIMVr for both isolated posterior leaflet prolapse ($n = 289$) and complex MVr ($n = 198$). They found a 100% repair rate and no conversions to sternotomy. Early mortality was 0.2% and the incidence of perioperative stroke for the entire cohort was 0.8%. Median echocardiographic follow-up was 362 days and 5-year freedom from recurrent regurgitation was 94.6% (96.2% simple; 92.7%, complex, $p = 0.67$) [21]. Another recently published series by Miceli et al. [22] reported on 703 patients undergoing MIMVS for degenerative mitral regurgitation: repair rate was 95.3% and they describe a mortality of 0.1%, a 1.3% risk of stroke, 1.8% of conversion to sternotomy and 4.4% of reoperation for bleeding. On follow-up, freedom from recurrent MR at 5 years was 93% and 5 year freedom from reoperation was 94%. Finally, Perier et al. [23] described another large series of MIMVr consisting of 842 patients with degenerative MR, and reported a 99.3% successful repair rate with a perioperative mortality of 0.2% and an incidence of stroke of 0.9%.

Current reported data indicate that in centers with a high volume of MVr and experienced in MIMVr, excellent results can be achieved in terms of quality of valve repair, repair rate

and repair durability (table 1). Once expertise is acquired, virtually all cases can be offered a MIMVr for all subsets of valve prolapse regardless of the complexity of the mitral pathology, including Barlow's disease. The generalized exception to this is the existence of significant valvular calcification. In these cases, general consensus is that they are still better served with a conventional approach, due to the difficulty in handling calcified tissues with MIMVS instrumentation.

SPECIAL SITUATIONS

Re-Operative Mitral Surgery

One of the biggest theoretical benefits of MIMVS is the avoidance of sternal re-entry in reoperations. This technique offers the advantage of requiring very little dissection of cardiac structures and adhesions (especially with the use of endo-aortic balloon occlusion) and is particularly attractive in the presence of patent coronary grafts. Several case-control studies have shown that MIMVS seems to be superior to redo-sternotomy in this scenario. Sharony et al. [26] found similar mortality but a lower rate of wound complications and transfusions, with a shorter postoperative stay. Similar results were found in other case-control studies in terms of duration of intubation, transfusions, and hospital stay [27] and even in mortality [28]. A recent study from the University of Pennsylvania group reported on their experience in reoperative mitral surgery, comparing MIMVS (n = 67) with a redo-sternotomy approach (n = 343); they found that MIMVS offered similar repair rates (19% vs. 22%), mortality (3% vs. 6%), stroke (3% vs. 3.1%) and a trend towards a shorter hospital stay (mean 11 days vs. 14 days; $p = 0.07$) [29]. In another large series published recently, Ricci et al. [30] reported on their results in 241 MIMVS reoperations; they found a mortality of 4.9% and an incidence of major stroke of 5.8%. In their experience, stroke rate dropped dramatically over time, and remained at 0% over the last two years of their series.

Despite all the theoretical advantages and the cumulative evidence supporting MIMVS for reoperations, the lack of studies showing clear benefits in hard end-points (such as in mortality and risk of stroke) together with the higher technical difficulty associated with these procedures have precluded the widespread use of MIMVS for reoperations in many institutions, although it will probably continue to increase.

Older Patients

Elderly patients have greater frailty and are at a particular high risk of complications after cardiac surgery. A recent meta-analysis reported a postoperative mortality of 13% after MVR and 7% after MVr, with a stroke rate of 4% and 3% respectively [31] (although data for isolated mitral surgery was not reported). Elderly patients are a particularly interesting population to whom MIMVr may offer an attractive perspective of a less traumatic operation and a faster recovery. Several studies have looked into this particular topic and seem to conclude in favor to MIMVr. Grossi et al [32], reviewed 111 patients over 70 years of age

Table 1. Mitral repair for degenerative disease

Study	Year	Time span	Patients	Repair Rate	Neurological Complications	Mortality	5y freedom recurrent MR	Comments
Suri et al. (21)	2015	2008-2015	487	100%	0.8%	0.2%	94.6%	-100% degenerative disease. -100% robotic with transthoracic clamping.
Miceli et al. (22)	2015	2003-2011	703	95.3%	1.3%	0.1%	93%	-Direct aortic cannulation (87%), endo-aortic balloon (9%). -Intrathoracic aortic clamping. -Concomitant tricuspid operations in 11%.
Akowuah et al. (24)	2015	2003-2013	190		1.6%	1.1%	2.1% reoperated during follow-up (1–5 years)	
Perier et al. (23)	2013	2006-2012	842	99.3%	1.4% (major stroke 0.6%)	0.2%	Not reported	-100% Degenerative disease. -Transthoracic clamping. -Concomitant tricuspid operations in 4%.
Grossi et al. (25)	2012	1995-2007	1282	NR	2.3%	1.1%*	Not reported	-Direct aortic cannulation in 69.3%. -Endoballoon in 29.1%. -Degenerative in 73.2%. *In patients with degenerative disease.
Pereda et al. (unpublished data)		2013-2015	102	100%	1%	0%	97.2% (1-4 years)	-Transthoracic clamping. -100% degenerative disease.

undergoing MIMVS and compared them to 259 patients on the same period having a redo-sternotomy; they found that MIMVS had a significantly lower risk of wound complications or **sepsis (1.8% vs. 7.7%; $p = 0.027$)**, plasma transfusion (median 1.0 unit vs. 2.0 units; $p = 0.04$) and had a shorter hospital stay (11.6 days vs. 17.6 days; $p = 0.001$). Similarly, Tabata et al. [33] reported on MIMVr in 123 patients over 70 years of age, with a mortality of 1.6% and a 5-year survival of 87%. In 2013, the Leipzig group reported on their results in 191 octogenarians undergoing MIMVS [34], they found a perioperative mortality of 3.1% and no reported cases of stroke. Very recently, Minol et al. [35] reported on 34 octogenarian patients undergoing MIMVS (44.1% with concomitant tricuspid repair), with a postoperative mortality and a stroke rate both of 5.9% and no mortality in the isolated mitral subgroup. These results are particularly interesting now that an increasing number of elderly patients are being treated with transcatheter approaches and indicate that a substantial amount of patients can still be offered the possibility of a surgical MVr with excellent results in a minimally invasive fashion.

Endo-Aortic Balloon vs. Transthoracic Aortic Clamping

The use of the endo-aortic balloon occlusion device allows isolating the aortic root from the systemic perfusion and the delivery of antegrade cardioplegia, without the need to cross-clamp the aorta. Typically, it is retrogradely advanced from the femoral artery through a specially designed port on the arterial perfusion cannula and placed in the ascending aorta under trans-esophageal echocardiogram guidance. Once in place it is inflated to occlude the aorta, so the aortic root is excluded from circulation and antegrade cardioplegia is delivered through the tip of the device to arrest the heart. Great care must be taken to assure the balloon does not occlude the innominate artery (with the subsequent risk of neurological injury) nor migrates proximally with the risk of injuring the aortic valve. One of the main concerns regarding its use is the associated risk of aortic dissection. It has been shown that the risk of aortic dissection decreases greatly with experience, thus reflecting the existence of a learning curve. In the first report of the Port Access International Registry (PAIR) in 1999 [36], the incidence of aortic dissection was 1.3% and then decreased to 0.18% on the second half of the study (however, it has to be pointed that most patients in this study were coronary revascularizations and not mitral operations).

There are some studies that have looked into this issue, comparing cases performed with endo-aortic balloon occlusion or transthoracic aortic cross-clamping. Onnasch et al. [37] found a significant increase in neurological complications with the use of the balloon (8.1% vs. 1.8%; $p = 0.05$) and a higher mortality (5.2% vs. 3.1%; $p < 0.04$). After these findings, the Leipzig group abandoned intra-aortic occlusion in favor of the transthoracic clamp as their preferred method for non-redo cases. Similarly, other authors have also found better results using trans-thoracic clamping in terms of blood loss, operative times and costs [38, 39]. The endo-aortic balloon is an expensive piece of disposable equipment and the routine use of the transthoracic clamp has been shown to reduce costs on disposables up to \$2.800 per case [39]. However, as mentioned before, the rate of complications related to the use of the balloon is tightly dependent on operator experience and many groups use the balloon as their preferred method, reporting very low complication rates after the learning curve is surpassed. In a recent multicentric report, Casselman et al. [40] described excellent results with the use of the

balloon when reviewing their most last 50 cases (all surgeons had already more than 100 procedures performed each) and with a 10.6% of redo-procedures: mortality 1.4%, stroke 0.8%, reoperation for bleeding 4.8% and no aortic dissections. However, even in their experienced hands, 2% of the patients required conversion to transthoracic clamping.

CONCLUSION

MIMVr has been increasingly performed over the last 20 years. There is growing evidence that it provides excellent results, comparable to conventional mitral surgery performed through a full sternotomy. MIMVr can now be offered to the vast majority of patients who have degenerative MR, providing a better cosmetic result, quicker recovery and without a tradeoff in repair rate and durability. It is also feasible in many traditionally difficult subsets of indications such as the elderly, reoperations, endocarditis or Barlow's disease. Large randomised controlled trials are underway and results from these are still awaited.

ABSTRACT

Background: Atrial fibrillation (AF) is the most common complication during the perioperative period of coronary artery bypass graft (CABG) surgery.

Objective: To evaluate the predictive power of different clinical and echocardiographic parameters for the occurrence of perioperative AF (POAF).

Methods: We studied 58 patients without previous history of AF undergoing elective CABG. We analyzed different demographic factors, clinical parameters, perioperative characteristics and the echocardiographic variables: left/right atrial volume index (L/RAVI), left ventricular end-diastolic diameter, ejection fraction, tissue velocities at the mitral and tricuspid annulus during early and late diastolic filling (Em, Am, Et and At, respectively) as well as interatrial asynchrony time (IAA) and global functional index.

Results: Of 58 patients, 14 patients (24%) developed POAF. Demographic factors, clinical characteristics and perioperative variables didn't show a significant difference between patients with or without POAF. Patients with POAF had larger LAVI and RAVI and higher IAA. After a Linear Regression Analysis, IAA, LAVI, smoking and female

* Corresponding Author's Email: ianasimova@gmail.com; Fax: +35928229388.

gender turned out to be independent predictors for the occurrence of POAF. For IAA and LAVI we performed a ROC analysis and found that IAA values ≥ 32 ms had 100% sensitivity and 82% specificity, while LAVI values ≥ 29 ml/m² showed 86% sensitivity and 52% specificity for the occurrence of POAF.

Conclusion: For a relatively small patient group without previous history of AF and undergoing CABG surgery IAA, LAVI, smoking and female gender were independent predictors for the occurrence of POAF. The strongest predictor for POAF was IAA with the cut-off value of 32 ms.

Keywords: atrial fibrillation, coronary artery bypass surgery, echocardiography; perioperative period, interatrial asynchrony, left atrial volume index

INTRODUCTION

Atrial fibrillation (AF) is not only the most common form of supraventricular arrhythmia but also the most frequent complication after coronary artery bypass graft (CABG) surgery. Its prevalence ranges between 20 and 40% and it increases considerably the cost of treatment and lengthens the in-hospital stay [1-3]. Being itself a postoperative complication, AF can lead to a succession of other complications in this vulnerable period, namely: haemodynamic instability, exacerbation or occurrence of heart failure symptoms, bleeding from anticoagulation, increased incidence of myocardial infarction and thromboembolic complications, including stroke [4].

Previous history of AF is considered as one of the strongest predictors of the occurrence of this kind of arrhythmia in the perioperative period [5]. Many patients, however, develop their first episode of AF after CABG surgery.

Numerous studies have sought to identify predictors of AF after CABG. Their number is a proof of clinicians' futility to prevent the occurrence of postoperative AF (POAF) in unselected patients [2, 3, 6-9].

Regarding echocardiographic predictors of early POAF different studies have reported conflicting results: some of them finding a good correlation between the deviation in certain echocardiographic variables and the occurrence of POAF [10-12], while others have not been able to find such a relationship [13, 14]. These kinds of studies could be further subdivided to such that incorporate tissue Doppler imaging and measurement of myocardial deformation [10-11], and to studies evaluating more conventional echo-parameters [12-14].

The aim of the present study was to evaluate the prognostic significance of different clinical and echocardiographic parameters for the occurrence of POAF.

METHODS

Study Group

The study was prospective and the participants were consecutively enrolled. Our study group included 58 patients with no previous history of AF, evaluated between 02.2010 and 12.2011, who underwent elective CABG surgery. During the recruitment period 438 CABG

procedures were performed, of whom nearly one half were isolated coronary revascularization (211 cases). Baseline clinical characteristics of the patients are presented in Table 1.

Table 1. Demographic characteristics and risk factor distribution for the whole group of patients

Clinical variable	Distribution n = 58
Age – mean ± SD	64.4 ± 9.2
Male – n (%)	41 (71%)
BMI – mean ± SD	27.9 ± 4.4
AH – n (%)	56 (97%)
DM – n (%)	24 (41%)
Dyslipidemia – n (%)	54 (93%)
Family history of CAD – n (%)	11 (20%)
Smokers – n (%)	29 (50%)
COPD – n (%)	8 (14%)
History of MI – n (%)	32 (55%)
RCA stenosis – n (%)	52 (90%)
Digoxin use – n (%)	1 (2%)

SD – standard deviation; BMI – body mass index; AH – arterial hypertension; MI – myocardial infarction; COPD – chronic obstructive pulmonary disease; RCA – right coronary artery; n – number.

Inclusion criteria: patients admitted at our institution and scheduled for an elective CABG were considered eligible if they had no previous history of AF.

Exclusion criteria were the need for a combined surgical procedure (i.e., presence of a significant valvular heart disease, ascending aortic aneurism requiring repair or congenital heart disease), history of AF or treatment with antiarrhythmic drugs class I or III, unstable clinical condition.

Beta-blockers and statins, as a part of the usual treatment in the presence of coronary artery disease (CAD) were continued in the perioperative period. Actually, all patients in our study group were taking beta-blockers and statins - two drug classes for which a prophylactic role against the occurrence of POAF has been suggested. Only one of the patients was taking a digitalis glycoside as a part of a heart failure regimen. Conventional monitoring was applied during the first postoperative days spent in Intensive Care Unit; later on patients were followed using telemonitoring till dehospitalization. AF was defined as fibrillation lasting more than one hour and precisely verified by skilled personnel.

Echocardiographic Evaluation

Standard transthoracic echocardiography was performed on the day before the scheduled operation in a left lateral position with a scanner Aloka Prosound SDD- α 10 and a 3.5 MHz transducer. The following echocardiographic parameters were studied: left artial volume index (LAVI) (ml/m²) by two-plane area-length method in a four-chamber and two-chamber apical view obtained just before mitral valve opening, right artial volume index (RAVI) (ml/m²) by the same method in a four-chamber apical view, left ventricular enddiastolic

diameter (LVEDD) (mm) and sum of the septal and posterior wall thickness (SpPW) (mm) in a parasternal long-axis view from two-dimensional guided M-mode tracings, ejection fraction (EF) (%) by biplane Simpson method, tissue velocities at the mitral and tricuspid annulus during early and late diastolic filling (Em, Am, Et and At, respectively) (cm/s) in an apical four-chamber view, the time from the onset of P wave on the surface ECG to the onset of A wave on the tissue velocity curve for the lateral segments of the mitral and tricuspid annulus (P-Am and P-At, respectively) (ms), the interatrial asynchrony time (IAA) measured as (P-Am) – (P-At) (ms) (Figure 1) and the global functional index (GFI) using the calculation $(E/E')/S'$ (cm/s), where E is the transmitral early diastolic velocity and S' and E' are peak systolic and early diastolic tissue velocities, respectively – a mean value between the septal and lateral mitral annulus. All Doppler measurements were calculated as an average of three beats.

Statistics

We tested the distribution of continuous variables using the Kolmogorov-Smirnov test. Normally distributed data were presented as mean $\pm$ standard deviation (SD), whereas non-normally distributed data – as median and interquartile range (IQR) (the difference between the 25th and 75th percentile). Categorical variables were presented in percentage terms.

Clinical variables and echocardiographic parameters between the two studied groups (with or without AF) were compared using an independent samples t test for normally distributed data and the Mann-Whitney U test for non-normally distributed data. Categorical variables, presented in percentage terms, were compared with Chi square test.

We performed a multivariable analysis using Linear Regression Model using the stepwise procedure with a criteria to enter ≤ 0.05 and criteria to remove ≥ 0.1 . The sensitivity and specificity for some of the continuous variables were assessed using the receiver operator characteristics (ROC) curve. We estimated the areas under the curve (AUC) with 95% confidence intervals (CI) under the nonparametric assumption. A two-tailed p value < 0.05 was considered statistically significant. Statistical analysis was performed using SPSS statistical software for Windows version 13.0.

Figure 1. Measurement of interatrial asynchrony (IAA): IAA = time (A) – time (B).

Ethics

Detailed preoperative echocardiographic evaluation was performed after an informed consent was obtained from the patients. The study was in accordance with the Declaration of Helsinki.

RESULTS

From the 58 patients we have studied, 14 (24%) developed POAF. Between these two groups of subjects (with or without POAF) we compared the following clinical factors and potential AF predictors in the perioperative period: age, gender, presence of arterial hypertension (AH), diabetes mellitus (DM), dyslipidemy, family history of early CAD, chronic obstructive pulmonary disease (COPD), smoking status, history of previous myocardial infarction (MI), preoperative use of digoxin, presence of a stenosis of the right coronary artery (RCA), aortic cross-clamp time, graft number, use of arterial graft – left internal mammary artery (LIMA), conventional on-pump versus off-pump CABG (OP-CABG), mechanical ventilation time, perioperative MI, postoperative pneumonia, need for intra-aortic balloon pump (IABP) and total amount of intravenous fluids – Table 2. Patients with and without POAF did not have a significant difference in any of the clinical parameters.

Figure 2. ROC analysis for IAA values regarding the occurrence of POAF. AUC - area under the ROC curve.

We further compared the preoperatively measured echocardiographic parameters (see Methods) between the groups of patients who did or did not develop postoperative arrhythmia – Table 3. Several of these parameters did show a significant difference between the groups – patients with POAF had larger LAVI and RAVI, longer time from the onset of P wave on the

surface ECG to the onset of A wave on the tissue velocity curve for the lateral segments of the mitral annulus (P-Am) and respectively higher value for the asynchrony index (IAA) compared to patients who did not develop POAF. When we performed a multivariable analysis with Linear Regression Model we found that the following variables were independent predictors for the occurrence of POAF: IAA, LAVI, smoking and female gender. IAA was included in all of the 4 models, created by the statistical software, LAVI - in 3 of them, smoking - in 2 of them and female gender - only in the last model, which combined all 4 variables and had the highest R square (0.92, $p < 0.001$). For the variable that differed most between both studied groups and at the same time was the most potent independent predictor for the occurrence of POAF - IAA, we then performed a ROC analysis - Figure 2. The area under the ROC curve (AUC) was high (0.941, $p < 0.001$) and the analysis showed us that IAA values ≥ 32 ms had 100% sensitivity and 82% specificity for the occurrence of POAF.

Table 2. Comparison of clinical factors and potential POAF predictors between patients with or without POAF

Clinical variable	POAF n = 14	No POAF n = 44	Significance (p)
Age – mean $\pm$ SD	67.1 $\pm$ 6	63.5 $\pm$ 9.9	ns
Male – n (%)	11 (79%)	30 (68%)	ns
BMI – mean $\pm$ SD	28.3 $\pm$ 3.4	26.9 $\pm$ 5.1	ns
AH – n (%)	14 (100%)	42 (96%)	ns
DM – n (%)	5 (36%)	19 (43%)	ns
Dyslipidemia – n (%)	13 (93%)	41 (93%)	ns
Family history of CAD – n (%)	3 (21%)	8 (18%)	ns
Smokers – n (%)	9 (64%)	20 (45%)	ns
COPD – n (%)	2 (14%)	6 (14%)	ns
History of MI – n (%)	8 (57%)	24 (55%)	ns
RCA stenosis – n (%)	13 (93%)	39 (87%)	ns
Digoxin use – n (%)	0	1 (2%)	ns
Aortic cross-clamp time (min) – mean $\pm$ SD	70.4 $\pm$ 24.5	69.1 $\pm$ 26.9	ns
Graft number – mean $\pm$ SD	3 $\pm$ 0.9	3.1 $\pm$ 0.8	ns
LIMA – n (%)	14 (100%)	43 (98%)	ns
OP-CABG – n (%)	1 (7%)	7 (16%)	ns
Mechanical ventilation time (hours) – mean $\pm$ SD	11.9 $\pm$ 2.8	15.4 $\pm$ 5.2	ns
Perioperative MI – n (%)	1 (7%)	6 (14%)	ns
Postoperative pneumonia – n (%)	0	2 (5%)	ns
IABP – n (%)	0	4 (9%)	ns
IV fluids (ml) – mean $\pm$ SD	3482 $\pm$ 913	3719 $\pm$ 1185	ns

SD – standard deviation; BMI – body mass index; AH – arterial hypertension; MI – myocardial infarction; COPD – chronic obstructive pulmonary disease; RCA – right coronary artery; LIMA – left internal mammary artery; OP-CABG – off-pump coronary artery bypass grafting; IABP – intra-aortic cross clamp; iv – intravenous; n – number; ns – statistically nonsignificant difference.

We performed also a ROC analysis for LAVI – another echocardiographic parameter that differed significantly between both groups and turned out to be an independent predictor for the occurrence of POAF (Figure 3). The AUC here was not so large – 0.713, $p = 0.017$; LAVI values ≥ 29 ml/m² showed 86% sensitivity and 52% specificity for the occurrence of POAF.

Table 3. Comparison of preoperatively measured echocardiographic between patients with or without POAF

Echocardiographic parameter	POAF n = 14	No POAF n = 44	Significance (p)
EF (%) – mean ± SD	62.9 ± 6.7	58.2 ± 8.9	ns
LVEDD (mm) – mean ± SD	50.4 ± 5.1	50.9 ± 5.8	ns
LAVI (ml/m ²) – mean ± SD	37.1 ± 9.1	30.8 ± 9.8	0.039
RAVI (ml/m ²) – mean ± SD	24 ± 6.6	19.4 ± 5.9	0.015
SpPW (mm) – mean ± SD	23.5 ± 2.9	22 ± 3.5	ns
Em (cm/s) – mean ± SD	8.9 ± 2.7	8.9 ± 2.7	ns
Am (cm/s) – mean ± SD	11.2 ± 2.8	10.7 ± 3.3	ns
Et (cm/s) – mean ± SD	10.3 ± 3.1	9.8 ± 2.9	ns
At (cm/s) – mean ± SD	15.1 ± 3.8	14.2 ± 4.1	ns
P-Am (ms) – mean ± SD	86.9 ± 14.4	68.9 ± 18.8	0.002
P-At (ms) – mean ± SD	43.9 ± 17	53.2 ± 19.6	ns
IAA (ms) – mean ± SD	43.6 ± 10.1	20 ± 12.6	< 0.001
GFI (cm/s) – mean ± SD	1.2 ± 0.3	1.5 ± 0.5	ns

SD – standard deviation; LAVI – left atrial volume index; SpPW – sum of the septal and posterior wall thickness; Em – tissue velocity at the mitral annulus during early diastolic filling; Am – tissue velocity at the mitral annulus during late diastolic filling; Et – tissue velocity at the tricuspid annulus during early diastolic filling; ; At – tissue velocity at the tricuspid annulus during late diastolic filling; P-Am – the time from the onset of P wave on the surface ECG to the onset of A wave on the tissue velocity curve for the lateral segments of the mitral annulus; P-At – the time from the onset of P wave on the surface ECG to the onset of A wave on the tissue velocity curve for the lateral segments of the tricuspid annulus; IAA – interatrial asynchrony time; GFI – global functional index; ns – statistically nonsignificant difference.

Figure 3. ROC analysis for LAVI values regarding the occurrence of POAF. AUC - area under the ROC curve.

DISCUSSION

In the present study with 58 elective CABG patients we observed a 24% incidence of POAF, which was comparable with the results from previous studies [1-3]. None of the demographic factors, clinical characteristics or perioperative parameters showed a significant difference between the groups of subjects with or without POAF. Patients with POAF, however, had larger atrial volumes (LAVI and RAVI) and more pronounced interatrial asynchrony (higher IAA values). From the multivariable Linear Regression Analysis IAA, LAVI, smoking and female gender turned out to be independent predictors for the occurrence of POAF. The ROC analysis for IAA and LAVI resulted in a statistically significant AUC, with a better predictive power (higher values for sensitivity and specificity) for the asynchrony index.

The possibility to predict the occurrence of POAF is very attractive. It would enable the clinician to detect a group of patients with a high risk for the development of this arrhythmia, to administer timely prophylactic antiarrhythmic therapy and to avoid the excessive morbidity imposed by this postoperative complication. On the other hand, patients who have low risk for the development of POAF could be spared the side effects of antiarrhythmic drugs.

There are some clinical factors that clearly identify a high risk group for POAF - e.g., previous history of AF, usually accompanied by atrial enlargement, LV systolic dysfunction and valvular involvement [5]. AF could, however, occur also in the early postoperative period of elective CABG patients without such risk factors.

Different clinical factors have been identified as possible predictors for POAF in clinical studies. In a prospective study of 302 CABG patients age, LA dimension, P wave morphology, failure to graft the RCA and postoperative adrenergic use were independently predictive of POAF [12]. In another study, which, however, had a retrospective design, 157 patients with POAF were compared with 191 subjects without such rhythm disorder after CABG [5]. The authors found a significant correlation between the occurrence of POAF and age >65 years, history of AF, presence of COPD, LV EF < 40%, proximal lesion of the RCA, bypass time > 120 min, significant intraoperative myocardial ischemia, positive fluid balance, and inotropic support with higher catecholamine doses.

In the present study the only clinical factors (outside the echocardiographic parameters) shown to be independently predictive for POAF, were female gender and smoking status. The female subgroup, however, was considerably small (17 patients) and the percentage of female patients and smokers was similar between the groups with or without POAF (t-statistics).

Studies regarding echocardiographic predictors for POAF give more consistent results, with left atrial volume or dimensions proven to have independent prognostic significance for the occurrence of this arrhythmia in the majority of studies [10, 11, 14], although there are also results pointing to the opposite. Tissue Doppler derived myocardial velocities and deformation indices have also been studied in this setting, the results generally showing that patients with POAF have reduced mechanical function of the atria compared to patients without perioperative arrhythmia [10, 11]. Other studies, however, have not found a correlation between tissue Doppler parameters and the occurrence of POAF [14].

Interatrial asynchrony has not been studied in the setting of CABG patients (determining therefore the main contribution of the present study). It has been evaluated, however, in a group of 37 patients with non-valvular paroxysmal AF, followed for 28 months [15]. During

this period 8 of the patients developed persistent AF. Significantly higher IAA values were present in this group, with the cut-off value $IAA \geq 34$ ms showing the highest sensitivity and specificity for progression of paroxysmal to persistent AF.

In the present study we were able to prove that not only atrial enlargement but also interatrial dyssynchrony present in patients with a negative AF history have a predictive power for the development of supraventricular arrhythmia in the early postoperative period. It should be noted that the IAA cut-off value in our study ($IAA \geq 32$ ms) was quite similar to the IAA cut-off value in the study by Sakabe et al. [15], although in a different clinical setting.

POAF episodes were not considered as an indication for long-term anticoagulation therapy in our group. At hospital discharge we recommended to these patients to perform an ambulatory Holter ECG or ECG telemonitoring in order to detect episodes of paroxysmal atrial fibrillation and to enable an optimal antithrombotic management.

The study had several limitations: the study group was considerably small, tissue Doppler derived indices were restricted to myocardial velocities and the occurrence of POAF was evaluated only in the early postoperative period (in fact - the most vulnerable one). We have not performed a long term follow-up in our patient group and do not have data about prognostic implication of POAF on mortality and future episodes of paroxysmal / persistent AF. As a result from the relatively small sample size the results of the present study should be interpreted with caution and our conclusion cannot be directly translated into a change in the patient care paradigm. The results from a larger study (presently ongoing in our institution) will be needed to either confirm or deny our findings. A deficiency of w-3 fatty acids and magnesium in the atrial tissue can also be a risk factor of AF among these patients.

In conclusion, for patients without previous history of AF and undergoing elective CABG surgery IAA, LAVI, smoking and female gender were independent predictors for the occurrence of POAF. The strongest predictor for POAF was IAA with the cut-off value of $IAA \geq 32$ ms implying a significantly higher risk for this rhythm disorder.

ABSTRACT

The peritoneal cavity is the largest potential space in the body. With its own lymphatic and vascular systems, it is critical to appreciate the biology of the peritoneum to better understand how disease may spread. For example, benign or low-grade malignancies may spread along the peritoneal surface by exploiting the lymphatic flow patterns of peritoneal fluid. Any pathologic process involving the peritoneal cavity can easily disseminate throughout this space by means of unrestricted movement of fluid and cells. These varied mechanisms of disease spread necessitate a range of therapeutic options including the administration of intra-abdominal chemotherapies.

In the past, cancer dissemination to peritoneal surfaces (i.e., carcinomatosis) was universally lethal with limited survival. Peritoneal carcinomatosis constitutes 10-12% of colorectal cancer metastases and 40% of gastric cancer metastases. This chapter discusses the peritoneal surgical treatment options for mucinous peritoneal tumors of the gastrointestinal tract. Cytoreductive surgery (CRS) entails removing all visible disease within the abdomen. This is followed by administration of hyperthermic intraperitoneal chemotherapy (HIPEC). CRS/HIPEC has become a well-recognized, standardized method in a select patient population for treatment of mucinous carcinomatosis. An approach to this treatment strategy is detailed in this chapter. Though CRS/HIPEC by experienced surgeons has increased survival for patients with primary peritoneal cancers and peritoneal metastases, multimodality treatment options must always be considered.

INTRODUCTION

The metastatic progression of malignant tumors of the gastrointestinal tract can occur by different mechanisms, including the hematogenous, lymphatic, and peritoneal surface routes. Benign or low-grade malignancies may also spread along the peritoneal surface by exploiting the flow patterns of peritoneal fluid. These varied mechanisms of disease spread necessitate a range of therapeutic options beyond the rote administration of systemic cytotoxic drugs. When cancers metastasize by the hematogenous and lymphatic routes, it is logical and intuitive to administer intravenous chemotherapies to achieve direct cytotoxic effects. However, when cancers progress exclusively or predominantly within the peritoneal cavity, the direct exposure of intravenous drug to tumor volume is limited; thus the cytotoxic effects are often suboptimal. Indeed, patients with predominance of peritoneal carcinomatosis, in contrast to visceral metastasis, often have poorer rates of overall survival because of the lower efficacy of systemic therapies in that setting [1]. Therefore, patients with peritoneal surface disease may benefit from a therapeutic approach that directly addresses its unique mechanism of disease progression.

In the 1970s a multidisciplinary approach to better manage intra-peritoneal cancer spread was developed [2-4]. This multimodal regimen consists of two major steps. In the first step, the surgical team performs operative resection to eradicate all sites of gross disease (i.e., cytoreductive surgery, CRS). In the second step, heated chemotherapy is instilled intraoperatively into the peritoneal cavity to eradicate all sites of microscopic disease (i.e., hyperthermic intraperitoneal chemotherapy, HIPEC). Although CRS and HIPEC are applied worldwide, there remains much debate and controversy regarding its indications, techniques, and efficacy. In this chapter we will examine CRS and HIPEC for mucinous gastrointestinal cancers while describing our experience on how to perform this complex multimodal treatment approach.

UNDERSTANDING THE PERITONEUM

It is critical to appreciate the biology of the peritoneum to better understand how disease may spread within the peritoneal cavity and how to optimally manage this disease. In its very simplest form, the peritoneum is the serous membrane supported by a thin layer of connective tissue that lines the abdominal cavity. It has both parietal and visceral components with the parietal peritoneum covering the inner surface of the abdominal walls, the diaphragm, and the pelvis; whereas the visceral peritoneum envelops the intraperitoneal organs and covers the anterior surface of retroperitoneal organs. The space between the parietal and visceral peritoneum is the peritoneal space; and within this space exists the fluid to lubricate the visceral surfaces. In its more complex form, the peritoneum doubles up to establish major extensions, including numerous mesenteries, the greater and lesser omentum, and complex ligamentous structures.

Figure 1. Operative photograph of a patient with appendiceal mucinous adenocarcinoma. The surgeon is holding the “omental cake.” The small intestine is spared of disease.

There is an intricate relationship between the circulation of peritoneal fluid, the major peritoneal extensions, and the intra-peritoneal organs. The peritoneal fluid, which is <100 mL under physiologic conditions, is constantly produced as a transudate and resorbed through major pores in the large surface area of the peritoneum to create a steady-state circulation [5]. The typical pattern of circulation occurs with peritoneal fluid flowing up the right para-colic gutter and leading up to the right hemidiaphragm [6]. Major pores under the right hemidiaphragm clear nearly 90% of peritoneal fluid. Not surprisingly, peritoneal surface disease may be frequently detected under the right hemi-diaphragm as tumor cells travel in the circulatory pattern of peritoneal fluid. The lesser and greater omentum also contribute to the steady-state peritoneal fluid circulation with sizeable pores throughout its large surface area [7, 8]. Thus, it is also a common location for both benign and malignant peritoneal disease spread. Massive replacement of the greater omentum by mucinous disease has been referred to as “omental cake” (Figure 1) [8, 9]. Finally, under pathologic conditions (e.g., cirrhosis, malignant ascites, etc.) peritoneal fluid may accumulate in the dependent areas of the peritoneal cavity (e.g., pelvis and lateral abdominal gutters), which are also frequent locations for peritoneal disease. Overall, the circulation of peritoneal fluid may help predict the progression of peritoneal surface disease (Figure 2).

MUCINOUS PERITONEAL TUMORS

Epithelial mucin-producing cells are at the core of the problem with mucinous peritoneal surface neoplasms. Mucins belong to a family of proteins also known as MUC glycoproteins. Intrinsically, these secreted mucins provide a physical barrier for epithelial cells lining the gastrointestinal tract and they contribute to the immune defense system on the mucosal surfaces [10-13]. These secreted mucins can accumulate and form voluminous gels slowly over months or years leading to a chronic condition that may elude detection until advanced stages of disease.

Pseudomyxoma peritonei (PMP) has been the term traditionally applied to the intraperitoneal dissemination of mucinous ascites from perforated mucinous cystadenoma of

the appendix [14]. In this condition, epithelial mucin-producing cells proliferate within the appendix, leading to occlusion of the lumen and expansion and eventual rupture of the appendix. If the mucinous cystadenoma is detected prior to rupture, simple appendectomy is sufficient to permanently eradicate disease (Figure 3). Extreme caution should be taken when laparoscopic appendectomy is attempted with large mucinous cystadenoma to avoid inadvertent rupture (Figure 4). When the appendix does rupture, which is frequently without symptoms, then semi-solid mucin may eventually fill the entire abdominal cavity leading to 'jelly belly' and 'omental cake.'

Figure 2. Typical locations of disease with peritoneal mucinous disease. Peritoneal surface disease from an appendiceal primary will follow the typical circulation of peritoneal fluid leading to disease under the hemi-diaphragms, omentum, and para-colic gutters. Gravity will also lead to disease in the pelvis.

Figure 3. Appendiceal mucinous cystadenoma from laparoscopic appendectomy. The pathologic specimen has been stained blue. The solid arrow points to the mucinous cystadenoma. The dashed arrow shows the diameter of the non-diseased appendix.

Figure 4. Massive appendiceal mucinous cystadenoma from open appendectomy. The solid arrow points to the terminal ileum. The base of the appendix was transected with a linear stapler.

The biologic aggressiveness of peritoneal surface disease has been classified to designate benign and low-grade malignant conditions together as disseminated peritoneal adenomucinosis (DPAM). In this schema, lesions are categorized as low-grade when they have scant simple to focally proliferative mucinous epithelium with minimal or little cytologic atypia or mitotic activity. In contrast, moderate or high-grade lesions of peritoneal mucinous carcinomatosis (PMCA) include lesions with more aggressive biologic disease that are composed of abundant mucinous epithelium with architectural and cytologic features of carcinoma. PMCA is typical for appendiceal mucinous adenocarcinoma or mucinous colorectal cancers and gastric cancers that violate the peritoneal cavity either by direct extension or by viscus rupture. This disease then spreads along the peritoneal surface with epithelial mucin-producing cells forming metastatic nodules in the absence of visceral metastases. The response to systemic therapies is generally poor and optimal management of these patients may include CRS and HIPEC in combination with systemic therapies [3, 4, 15-24].

CYTOREDUCTIVE SURGERY AND HEATED CHEMOTHERAPY

General Overview

Eradication of gross and microscopic disease by surgical resection and heated chemotherapy, respectively, are the principles of CRS and HIPEC. This treatment approach is ideally suited for disease processes that have peritoneal surface disease but lack visceral metastases; and generally excludes cancers that have metastasized outside the peritoneal cavity. Incomplete surgical resection of disease should be avoided since patients derive minimal to no survival benefit [1, 3, 16, 25-32]. As such, complete resection of all tumor volume to margin negative disease is the goal of CRS. The amount of disease burden may be estimated prior to surgical exploration with the Peritoneal Cancer Index (PCI). This scoring

system separates the abdominal cavity into 13 distinct regions. The operator assigns tumor burden scores for each of these regions based upon the Lesion Size (LS) of the tumor volume in each of those regions. The numerical value of these PCI scores have correlated with clinical outcomes; and patients with lower PCI scores generally fare better than patients with higher scores [33, 34].

Morbidity and Mortality of the Treatment Approach

Patients who undergo CRS and HIPEC may endure major physiologic stress from multi-visceral resection, rapid changes in fluid homeostasis, and alterations in body core temperature. Not surprisingly, there is considerable morbidity and mortality associated with this procedure with approximate rates approaching up to 50% and 5%, respectively [16, 21, 23, 24, 35-39]. Strategies to avoid unnecessary surgical steps and abandoning unsafe HIPEC protocols have improved the safety profile of these procedures without adversely impacting overall survival [40, 41]. In our practice we perform resection for grossly visible disease and generally avoid prophylactic or empiric resection except for the appendix and gallbladder. When disease is encountered on the surface of intra-peritoneal organs, we make concerted efforts to remove disease by stripping the peritoneal lining rather than resecting the entire organ en bloc. Finally, we avoid using D₅W in the hyperthermic perfusate, thus avoiding potentially serious electrolyte alterations.

Technique for Cytoreductive Surgery

For our cytoreduction procedures, we routinely use a generous midline incision with a Thompson retractor to provide full exposure. Once the peritoneal cavity is entered, mucin is typically removed with suction catheters. Tenacious, thick mucin may require manual removal using laparotomy pads. After initial exploration to rule out unresectable disease, we proceed with resection of all sites of gross disease. Regardless of detection of gross disease, we advocate mandatory resection of the greater and lesser omentum, appendix, and the gallbladder. We use a thermal energy device (Ligasure, Covidien) to remove the omentum by dividing the gastrocolic ligament close to the transverse colon from the hepatic to splenic flexures. The omentum is then divided along the greater curvature of the stomach while preserving the gastro-epiploic vessels. Appendectomy is performed using a linear stapling device, rather than using biodegradable suture to avoid its exposure to HIPEC. Similarly, titanium clips are placed on the cystic artery and duct during cholecystectomy.

For many patients, cytoreduction procedures will also require stripping of the right and occasionally left hemi-diaphragm. We use long Allis clamps to grasp the peritoneal lining of diaphragm and “strip” only gross disease. If the thoracic cavity is entered, we close the diaphragm around a red rubber catheter. A purse-string suture is placed around the catheter; and the catheter is removed and the suture tied down once the air in the thoracic cavity has been suctioned. Another common site of disease is on the liver surface. We have found that the bipolar hemostatic device (Aquamantys, Medtronic) is safe and effective for stripping Glisson’s capsule of the liver. Finally, the removal of intraperitoneal or retroperitoneal organs may sound contrary to the benign nature of low-grade malignancy; however, thick tenacious

mucinous disease may coat the pelvis, rectum, lesser curvature of the stomach, antrum of the stomach, the liver surface, and the porta hepatis. Therefore, it is common to perform major multi-visceral resection to completely remove disease even for patients with DPAM. Since mucinous disease tends to spare areas of active peristalsis, the small intestine is typically spared. In our experience we have identified lesions overlooked by other surgeons during combination operative resections. These examples of missed disease give us pause when considering laparoscopic HIPEC procedures.

Figure 5. Open technique for hyperthermic intraperitoneal chemotherapy. Multiple sutures have been placed to suspend the skin to the retractor system. Inflow and outflow catheters have been placed through openings in the mesh. A smoke evacuator has been placed above the opening.

Figure 6. Closed technique for hyperthermic intraperitoneal chemotherapy. Inflow and outflow catheters have been placed into the abdominal cavity and the skin has been closed with a continuous running suture.

Administration of Heated Intraoperative Chemotherapy

The rationale to use intra-peritoneal chemotherapy is to eradicate microscopic disease with higher local concentrations of chemotherapy that may enhance cytoreduction, which may be further potentiated by the cytotoxic effects of heat [4, 15, 16]. Once gross resection of disease is completed and prior to anastomotic reconstruction, we perform HIPEC. Anastomoses should be delayed until after HIPEC is completed to avoid exposing the fresh anastomosis to the peritoneal dosage of chemotherapy. For colorectal and appendiceal tumors, we instill oxaliplatin or mitomycin C into our perfusion circuit, whereas cisplatin is used for gastric cancer. Mitomycin C may be the chemotherapeutic agent of choice for patients with peritoneal surface disease of colorectal origin with the American Society of Peritoneal Surface Malignancies (ASPSM) advocating its use for this disease [40-42].

HIPEC has been performed using an open platform, referred to as the coliseum technique (Figure 5), in which the abdomen is left open and the operator manually stirs the chemotherapy perfusate to ensure equal distribution throughout the abdominal cavity [16, 43, 44]. Because of institutional or state restrictions, the open technique has been abandoned in some centers. The alternate approach is the closed technique (Figure 6) [41, 43-47], which is our preferred technique. We employ the Genesis Medical system (Figure 7), which utilizes two inflow catheters connected by a Y connector to a single primary catheter; and a single outflow “lasso” catheter. In our experience this system rapidly achieves goal temperature when the catheters have been placed and the skin closed; and we have observed no interruptions in HIPEC secondary to system or catheter malfunction.

Figure 7. The Genesis Medical system for hyperthermic intraperitoneal chemotherapy.

Once closed, the abdomen is warmed with hyperthermic saline to 41-42°C. Once the target temperature is reached, chemotherapy is infused into the circuit and perfused for 30-90 minutes. Once the perfusion has been completed, the hyperthermic chemotherapy fluid is drained from the abdomen. Next, the skin is reopened and the final anastomoses are performed or ostomies constructed.

CONCLUSION

Multimodal therapies for patients with primary peritoneal cancers and peritoneal metastases are continuing to improve and evolve. Instead of representing rapidly fatal disease as in the past, contemporary management of DPAM and PMCA with CRS and HIPEC has improved survival in the hands of experienced surgeons. Importantly, the implementation of standardized protocols and advances in HIPEC delivery systems has resulted in decreased rates of morbidity and mortality. We recommend adhering to the guidelines from The American Society of Peritoneal Surface Malignancies (ASPSM) on the use of HIPEC in our difficult to manage patients. This organization has provided HIPEC guidelines on chemotherapy administration, timing, and dosage and temperature settings to improve patient safety [41, 42, 48]. Despite these past improvements, additional investigational studies are needed to further improve the outcomes of patients with mucinous peritoneal disease.

Chapter 429

EXFOLIATION SYNDROME AND EXFOLIATIVE GLAUCOMA: FROM GENETICS TO SURGERY

Gábor Holló¹, MD, PhD, DSc and Andreas Katsanos², MD, PhD

²Department of Ophthalmology, University of Ioannina, Ioannina, Greece

ABSTRACT

Exfoliation syndrome (XFS) is a genetically determined systemic condition characterized by the production and accumulation of an abnormal protein, the exfoliative material. Though XFS is a systemic elastosis, the most significant clinical consequences occur in the eye (nuclear cataract formation, Zinn's zonule fragility, increased risk for cataract surgery complications and exfoliative glaucoma [XFG]). XFG is the most common type of secondary open-angle glaucoma, and is characterized by elevated intraocular pressure with high fluctuation, and rapid progression. XFG is typically a disease of the elderly. In many cases XFG starts as a clinically unilateral disease in eyes with XFS. This chapter summarizes the current knowledge on genetics, environmental factors, clinical characteristics, medical, laser and surgical treatment options. It also addresses the significance of systemic vascular diseases associated with XFS and XFG, and the need for consultation between the ophthalmologist and cardiologist or general practitioner during long-term management of the disease.

INTRODUCTION

Open-angle glaucoma is one of the most important causes of severe irreversible visual field deterioration, decrease of vision related quality of life, and blindness [1-4]. Due to global population ageing along with increased life expectancy, glaucoma will have an ever increasing impact in the next decades. Since open-angle glaucoma is a group of progressive diseases, end-of-life glaucoma related blindness is not uncommon [5, 6]. This chapter deals with one type of the open-angle glaucoma, the most common secondary open-angle glaucoma, exfoliative glaucoma (XFG) [2-4, 7]. XFG is different from primary open-angle glaucoma; it develops from exfoliation syndrome (XFS), a systemic condition. For several

decades XFG was considered a rare type of glaucoma and frequently remained unrecognized by ophthalmologists. In the recent years, however, both research and clinical interest in XFG have dramatically increased so that awareness of XFG is heightened worldwide.

EXFOLIATION SYNDROME

Exfoliation (or “pseudoexfoliation”) syndrome is a common genetically determined systemic condition characterized by the synthesis and accumulation of an abnormal protein, the exfoliation (or pseudoexfoliation) material (XFM). In XFS, elastin production and metabolism are disturbed, thus XFS is a systemic elastosis [3, 4]. Clinically, the signs of XFS are best detectable with slit lamp examination in the anterior segment of the eye after pupillary dilation. XFM appears on the anterior lens capsule in a typical distribution (“classic” XFS): a homogeneous central XFM area (“central disc”) in the pupillary area surrounded by a transition zone containing some XFM. The transition zone reflects the brushing effect of pupil movements on the XFM. Outside the transition zone a peripheral zone of XFM deposition is seen (Figure 1).

Detection of XFM is difficult without pupil dilation, particularly because in the early stages of XFS the amount of XFM is small and its distribution less obvious. Clinically XFS is frequently unilateral: at the slit lamp it is detectable only in one eye. However, XFS is always a systemic disease: even in apparently unilateral cases, XFM is ultrastructurally detectable in both eyes and in several extraocular tissues and organs [3, 4, 8]. In approximately 38% of unilateral presentations, XFS becomes clinically detectable in the seemingly uninvolved fellow eye in a decade [9]. Clinically XFS (and XFG) typically appears after 60 years of age.

Figure 1. Distribution of exfoliation material on the lens surface. A, central disc; B, transition zone; C, peripheral zone.

XFM is also frequently detectable on the pupil margin [10, 11], the corneal endothelium [12], the zonules and the anterior chamber angle where pigment granules liberated from the iris tissue due to XFS are typically accumulated and distributed along undulating lines on and anterior to the Schwalbe's line (Sampaolesi' line) [3, 4, 11]. The loss of melanin granules results in the typical "moth-eaten" appearance of the pupillary margin in XFS. The zonules holding the crystalline lens are also frequently damaged in XFS due to elastosis [3, 4, 8, 11]. As a consequence, dislocation of the crystalline lens or a previously implanted artificial intraocular lens (in-the-bag IOL dislocation) is not uncommon in eyes with XFS. When the crystalline lens is dislocated towards the anterior chamber, pupillary block and secondary angle closure glaucoma can develop [13]. Development of nuclear cataract is also typical in XFS [14]. In addition, the disturbance of elastin metabolism diminishes the resistance of the lamina cribrosa [15, 16]; leads to decreased blood-aqueous barrier function in the iris, which results in localized vascular occlusions in the anterior iris layer [17]; and increases the postoperative inflammatory reaction after extracapsular cataract surgery [14]. However, the most significant complication of XFS is the development of intraocular pressure (IOP) elevation and XFG, the most common secondary open-angle glaucoma worldwide [8, 18, 19].

EXFOLIATIVE GLAUCOMA

XFG develops from XFS, but most XFS eyes do not eventually convert to XFG. Initially, IOP increases and exhibits high diurnal fluctuation [20]. Later, mild structural alterations (e.g., retinal nerve fiber layer thinning) become detectable with imaging devices [20-22]. Ultimately, the increased oxidative stress in the anterior chamber and pigment liberation from the iris lead to further, typically very significant IOP elevation, which (in part due to the elastosis-related weakening of the lamina cribrosa) results in severe glaucomatous neuroretinal rim damage, increased optic disc cupping, severe retinal nerve fiber layer loss and severe visual field deterioration, in many cases already prior to the first ophthalmology visit [18, 19, 23]. Since the presence of XFG is frequently unilateral or the severity of glaucomatous damage is remarkably asymmetrical, most patients do not realize unilateral visual field deterioration until it becomes very severe, or until the fellow eye suffers from central visual field deterioration [13, 23]. The progression rate of XFG is almost 3 times faster than that of high-pressure primary open-angle glaucoma, and 4 times higher than that of normal pressure glaucoma [24, 25].

ROLE OF GENETIC ALTERATIONS, ENVIRONMENTAL FACTORS AND OXIDATIVE STRESS IN THE DEVELOPMENT OF EXFOLIATION SYNDROME AND EXFOLIATIVE GLAUCOMA

XFS is a genetically determined condition. It has recently been shown that 2 common single nucleotide polymorphisms (SNPs) of the lysyl oxidase-like protein 1 (LOXL1) gene are responsible for almost 100% of the population-related risk of XFS [26, 27]. In most white populations the risk alleles are G153D and R141L [26, 27]. The LOXL1 protein is responsible for elastin production and turnover in the whole body, thus its disturbed

translation and dysfunction explain several characteristics of intraocular and systemic alterations in XFS [16, 28]. It is important to note, however, that there are different risk alleles in various populations and these are also common in healthy individuals in whom XFS never develops [26]. Thus, currently unknown environmental factors are also believed to take part in the development of XFS. Very recently a novel association between XFS and calcium signaling has been established: one SNP of the calcium voltage-gated channel subunit alpha1A gene (CACNA 1A) confers 1.16 times increased risk for XFS [29]. The exact mechanism of LOXL1 and CACNA1A polymorphisms causing XFS remains to be determined.

It is important to recognize that conversion from XFS to XFG is not genetically determined, thus any genetic screening for XFG is impossible. The conversion from XFS to XFG is considered a result of environmental factors [26, 30-32]. The common mechanism of all environmental factors seems to be increased oxidative stress in the anterior chamber [28, 30, 33]. According to the current hypothesis, increased sunshine exposure provokes production of oxidative stress markers (e.g., 8-isoprostaglandin F_{2α}, endothelin 1) and depletion of antioxidant protection molecules (e.g., ascorbic acid) in the anterior chamber [33]. The oxidative stress, which is greater in XFG than in XFS, is supposed to cause nuclear cataract, dysfunction of the trabecular meshwork and zonular damage. The trabecular meshwork dysfunction is considered responsible for the IOP elevation and the large IOP fluctuation typical in XFG, and the zonular damage for phacodonesis, lens dislocation, or secondary angle closure glaucoma (when the luxated lens causes pupillary block or directly blocks the anterior chamber angle) [4]. Recently, based on population-based retrospective studies, it has been suggested that the amount of time spent outdoor in bright sunshine without sunglasses in young age (a proxy for ultraviolet light-induced oxidative stress in the anterior segment of the eye), high coffee consumption and decreased folate intake may be risk factors for the development of XFS and XFG in later life [30-32, 34, 35]. These hypotheses, however, require confirmation and further research. Figure 2 summarizes the proposed key mechanisms of the development of XFS and XFG.

Figure 2. Key mechanisms involved in the pathophysiology of XFS and XFG.

GLOBAL HEALTH SIGNIFICANCE

It has been estimated that roughly 60 to 70 million people in the world have XFS. Approximately 25% of them have high IOP, and one third of them (i.e., 5-6 million people) have XFG in at least one eye [3, 7, 8]. The global impact of XFG becomes even more obvious considering the fact that approximately half of the patients with glaucoma remain undiagnosed [7, 8, 36]. This fact can have a profound effect on individual patients and healthcare resources alike, because XFG is often difficult to control and has a poor long-term prognosis. Irrespective of the risk for glaucoma, the global impact of exfoliation should also be seen in the light of increased risk for cataract formation and increased risk for complications during or after cataract surgery [14, 37].

Numerous reports in the last several years have contributed to the rejection of the notion that XFS and XFG are entities peculiar to Scandinavia. In fact, these conditions have been identified in diverse populations worldwide and XFG may account for 20-25% of open-angle glaucoma cases globally [3, 7, 8]. In particular, over half of open-angle glaucoma cases may be due to XFG in countries such as Norway, Iceland, Greece, Turkey and Saudi Arabia [7, 8].

The prevalence of XFS in the United States is generally comparable to that in Western Europe but significant racial variations exist, since the condition is much more prevalent in whites than persons of African origin, and Spanish-American men are almost six times more likely to have XFS compared to non-Spanish-Americans [36, 39].

It is puzzling that local variations in prevalence of exfoliation can be remarkable. In Nepal, for example, XFS was detected in 12% of the members of the Gurung ethnic group, but only in 0.24% of age-matched non-Gurungs [39]. Similarly, in the Middle Norway survey XFS prevalence values of 10.2%, 19.9% and 21% were observed in three population cohorts from different municipalities who were examined simultaneously using the same criteria, even though the municipalities were lying only about 100 kilometers apart [40]. Obviously, the interplay of genetic and environmental factors (epigenetics) is a major determinant of exfoliation prevalence. Well-designed population-based studies rather than frequency reports or studies with convenience samples are needed in order to explore possible etiological associations.

CLINICAL CHARACTERISTICS OF XFG

Patients with XFG are typically older than patients with primary open-angle glaucoma (POAG) [13, 19]. In fact, XFG is very uncommon before the age of 50. Because XFG has a fast rate of progression, serious visual deterioration or even terminal damage is often seen in some patients at diagnosis, occasionally with remarkable inter-eye asymmetry [13, 23]. Since IOP is typically very high in eyes with XFG, subjective symptoms reported by patients may include dull ocular or retrobulbar ache, clouding of vision due to corneal edema, or sudden severe visual deterioration due to branch- or central retinal vein occlusion [41, 42]. However, most XFG patients do not experience symptoms. IOP characteristics in XFG deserve particular mention: these eyes usually have higher mean, higher peak and larger 24-hour and intervisit IOP fluctuation compared to eyes with POAG [43-45]. Furthermore, IOP peaks in eyes with XFG often occur outside office hours and can therefore remain unnoticed in typical

clinical settings [45, 46]. As a consequence, single daytime IOP measurements every few months may be inadequate as a means of evaluating a patient's overall IOP characteristics or the response to therapy. In addition to the worse IOP characteristics in eyes with XFG, the purported elastosis-induced biomechanical alterations of the lamina cribrosa that may render the optic nerve more vulnerable to effects of IOP elevation are thought to underlie the poorer long-term prognosis compared to POAG [15, 16, 23, 25]. It should be noted that gradual or sudden IOP elevation in treated and seemingly well-controlled eyes with XFG may occur. Thus, close follow-up over the long term is necessary even in apparently well-controlled XFG patients [3, 19]. A notable difference between XFG and POAG is that the former is not associated with a higher risk of IOP elevation following steroid treatment [47].

Medical Treatment

Because XFG is a high-pressure glaucoma with unpredictable characteristics (e.g., high spikes outside office hours), achieving a sufficiently low IOP throughout the 24-hour cycle is frequently difficult [23, 44, 45]. Medical therapy should ideally be tailored to the particular needs of eye with XFG [48, 49]. Prostaglandin analogues are common first choices in open-angle glaucoma due to their efficacy, convenient once-daily administration and favorable safety profile [50-52]. A 3-month, multicenter, single masked, prospective, parallel group study with XFG patients compared the diurnal efficacy of evening-dosed latanoprost 0.005% versus timolol 0.5% administered twice daily [53]. The authors found that latanoprost provided marginally superior diurnal IOP reduction and smaller IOP fluctuation compared to timolol. Although the efficacy difference between latanoprost (reduction from untreated baseline 24.9 mmHg to 17.4 mmHg) and timolol (reduction from untreated baseline 24.7 mmHg to 18.3 mmHg) for the diurnal IOP did not reach statistical significance ($P = 0.07$), the IOP reduction at the 8 a.m. time-point was significantly greater with latanoprost (-8.5 mmHg vs. -6.0 mmHg).

The investigators of a 6-month, single masked, prospective, parallel group study with IOP measurements at 8 a.m., 10 a.m. and 4 p.m. compared the IOP lowering efficacy of evening-dosed latanoprost 0.005% and travoprost 0.004% and the dorzolamide 2%/timolol 0.5% fixed combination dosed twice daily, in patients with XFG [54]. The mean untreated daytime IOP in all groups varied between 23.8 mmHg and 25.7 mmHg and the mean IOP reduction was 8.2 mmHg for latanoprost, 9.3 mmHg for travoprost and 11.5 mmHg for the dorzolamide/timolol fixed combination. This result, however, may not be representative for the true 24-hour IOP lowering efficacy of these medications in XFG since 2 of the 3 time points coincided with the post-instillation peak efficacy period of the dorzolamide/timolol fixed combination, thus overestimation of IOP lowering effect of the fixed combination was possible.

In a 24-hour, investigator-masked, crossover trial made on XFG patients, latanoprost 0.005% and travoprost 0.004% lowered the mean untreated 24-hour IOP (25.1 mmHg) by 7.3 mmHg (30.8%) and 7.8 mmHg (31.1%), respectively [55]. The efficacy difference between the two treatments was statistically significant mostly due to the IOP difference at the 6 p.m. time point (17.9 mmHg on latanoprost vs 16.7 mmHg on travoprost, $p < 0.01$).

In a 3-month, prospective, multicenter, investigator-masked, crossover trial comprising 129 XFG patients, the efficacy of latanoprost 0.005% and bimatoprost 0.03% was compared

[56]. The mean untreated diurnal IOP was 26.9 mmHg. Bimatoprost provided statistically and clinically significantly lower mean diurnal and individual time point IOP than latanoprost. The mean diurnal IOP values were 18.6 mmHg for latanoprost and 17.6 mmHg for bimatoprost. Only 34 patients (26.4%) on latanoprost versus 55 patients (42.6%) on bimatoprost achieved mean diurnal IOP < 17 mmHg. This difference is clinically relevant because a mean diurnal IOP < 17 mmHg has been shown to lower the risk of progression in XFG [25].

A 2-month, crossover, prospective, investigator-masked study conducted on treatment-naïve XFG patients assessed the efficacy of latanoprost 0.005% dosed in the evening and dorzolamide/timolol fixed combination dosed twice daily[57]. The mean untreated IOP (measured at 10 a.m.) was 31.2 mmHg, which decreased by 40.2% to 18.9 mmHg with latanoprost and by 42.8% to 18.1 mmHg with the fixed combination ($P = 0.21$). The results indicate that the 2-hour post-instillation peak efficacy of the dorzolamide/timolol fixed combination and the 14-hour post-instillation efficacy of latanoprost monotherapy are comparable in XFG.

The efficacy of fixed combinations of a prostaglandin analogue (latanoprost 0.005%, travoprost 0.004%, bimatoprost 0.03% or tafluprost 0.0015%) and timolol 0.5% has also been investigated in XFG [58-61]. In general, the use of fixed combinations offers a number of advantages: convenient once daily dosing, decreased ocular tissue exposure to preservatives, reduced systemic absorption of timolol compared to twice daily administration, and increased efficacy compared to that of the individual constituents[52, 62, 63]. The investigators of a 3-month, 24-hour crossover study found that in XFG patients the evening dosed travoprost/timolol fixed combination reduced the mean 24-hour IOP from 28.5 mmHg (untreated baseline) by 34.4% (9.8 mmHg), while the evening-dosed latanoprost/timolol fixed combination by 31.2% (8.9 mmHg) [58]. This difference was statistically significant ($P < 0.001$) [58]. In another crossover study, the mean 24-hour baseline IOP in a mixed population of POAG and XFG patients was 27.7 mmHg [59]. After 2 months of therapy, the mean 24-hour IOP was 19.2 ± 3.5 mmHg when the travoprost/timolol fixed combination was dosed in the morning, and 18.4 ± 3.3 mmHg when dosed in the evening ($P = 0.001$) [59]. In a 3-month, multicenter, prospective, single-masked, 24-hour crossover study conducted on XFG patients [60] the bimatoprost/timolol fixed combination was administered in the morning in one study phase, and in the evening in the other phase. The mean 24-hour IOP reduction from the mean untreated 24-hour value (29.03 mmHg) was 33.9% (9.84 mmHg) with morning dosing and 35.3% (10.2 mmHg) with evening dosing. This difference was statistically significant ($P = 0.005$). These results suggest that in XFG topical prostaglandin analog/timolol therapy is more effective when the drop is administered in the evening. Recently, the IOP lowering efficacy of morning-dosed preservative-free tafluprost/timolol fixed combination was evaluated in XFG patients who participated in a 6-month, randomized, double-masked, active controlled, parallel group, multicenter phase III study [61]. The mean untreated baseline IOP varied between 26.5 mmHg (4 p.m.) and 28.1 mmHg (8 a.m.). The mean time-wise IOP reduction ranged between 8.62 and 10.25 mmHg (31.8 to 36.7%), and the overall IOP reduction was 34.1%. The results discussed in this paragraph suggest that an IOP reduction of 31 to 36% from untreated baseline can be expected with once daily administration of all prostaglandin analogue/timolol fixed combinations. Currently there are no controlled data on the efficacy of combination therapy with 3 or more IOP lowering medications in XFG (e.g., a prostaglandin analogue and a topical carbonic anhydrase inhibitor/timolol fixed combination

or a prostaglandin analogue/timolol fixed combination and a topical carbonic anhydrase inhibitor).

Laser Treatment

Argon laser trabeculoplasty (ALT) exerts its IOP lowering effect by enhancing aqueous humor egress through the trabecular meshwork. It was initially hypothesized that the mode of action is mechanical distention of the collapsed trabecular meshwork [64, 65]. However, laser-induced enhancement of extracellular matrix turnover due to stimulation of trabecular cells has also been proposed [65]. Since energy absorption by melanin in the trabecular meshwork is necessary for ALT to be effective, patients with XFG are usually good candidates for this treatment because their eyes typically have debris laden, heavily pigmented anterior chamber angles.

ALT commonly provides significant IOP reduction in XFG eyes with high untreated IOP, at least in the first post-laser months or years [66-70]. Unfortunately, the hypotensive effect diminishes over time, conceivably due to the continuous accumulation of pigment granules and exfoliation material on the trabecular meshwork. A retrospective study evaluated the efficacy of ALT on 28 POAG and 26 XFG patients poorly controlled on medical treatment [70]. Failure was defined as IOP > 22 mmHg after 4 to 6 months following ALT, or need for filtering surgery. The authors found that despite an initially better response to ALT, patients with XFG eventually failed faster than patients with POAG. For instance, the cumulative probability of success after approximately 8 months was 59% and 77% for the XFG and POAG groups, respectively.

Another retrospective study compared the efficacy of ALT on 29 XFG eyes (mean follow-up time 23 months) and 66 POAG eyes (mean follow-up time 27 months) [67]. XFG patients had a greater percentage of IOP reduction in the first post-laser year compared to POAG patients. The IOP reduction in the XFG group varied between 28% and 38% (mean pre-laser IOP 25.8 mmHg), whereas in the POAG group it varied between 19% and 27% (mean pre-laser IOP 23.2 mmHg). The 1-year rate of failure (need for glaucoma filtering surgery; or an additional laser treatment; or IOP $\geq$ 22 mmHg; or IOP elevations up to 15% of the baseline IOP value in at least 2 visits) was 40% for POAG and 18% for XFG, while the 3-year failure rate for the groups was 58% and 47%, respectively ($P = 0.89$). The effect of ALT diminished over time and by three years both groups had comparable measures of success.

ALT was eventually proposed as primary treatment in patients with POAG [71]. A retrospective study also investigated the efficacy of ALT as primary therapy on 75 XFG and 93 POAG patients [66]. Using customized clinical criteria based on each patient's need for additional IOP lowering therapy, the probability of success (defined as no need for additional treatment) in the XFG group was 80% after 2 years, 54% after 5 years, and 36% after 8 years. The existing evidence suggests that in eyes with XFG and pre-laser IOP between 23 and 30 mmHg, clinicians can expect an approximately 20-40% pressure reduction from ALT during the first 4 post-laser years [66-68, 70].

Selective laser trabeculoplasty (SLT) employs a frequency-doubled Q-switched Nd-YAG laser to deliver low energy in brief pulses with a large spot diameter (400 μ m) to the surface of the trabecular meshwork [72]. The precise mechanism by which SLT enhances aqueous humor outflow remains unknown. SLT is considered to selectively target the pigmented

trabecular meshwork cells without causing obvious coagulative or disruptive changes. Therefore the technique can be repeated in eyes previously treated with ALT or SLT [72, 73].

In eyes with POAG, the efficacy of SLT has been found similar to that of ALT [73]. However, there is limited information on the comparative efficacy of SLT and ALT in XFG. A 6-month randomized trial evaluated the efficacy of SLT versus ALT on 76 inadequately controlled XFG eyes and XFS eyes with ocular hypertension [74]. SLT and ALT resulted in similar IOP reductions (6.8 mmHg and 7.7 mmHg, respectively, $P = 0.56$) from the corresponding pre-laser baseline values (SLT: 23.1 mmHg, ALT: 25.2 mmHg, $P = 0.03$). Moreover, an identical proportion of patients (73%) achieved at least 20% IOP reduction with either treatment at the 6-month post-laser visit. Other reports suggest that XFG and POAG eyes respond to SLT similarly both when the procedures are used as primary [75] or adjunctive [76, 77] interventions.

It is important to note that ALT and SLT are seldom adequate treatments for patients with high-pressure XFG, especially when considering that a low target IOP (<17 mmHg) is needed to prevent progression on the long term [25]. Nonetheless, these techniques can be considered in elderly XFG patients with suboptimal compliance, in XFG patients intolerant to medical therapy and in XFG patients who are poor candidates for filtration surgery.

Surgical Treatment

Glaucoma surgery is mainly reserved for eyes insufficiently controlled with medical and/or laser treatment; cases in which progression develops on maximal tolerated medical and laser treatment; and in patients intolerant or non-compliant to medical therapy. For several years trabeculectomy (typically with adjuvant 5-fluorouracil or mitomycin C) has been considered the gold standard surgical procedure in XFG [78, 79]. Evidence suggests that the long-term survival of trabeculectomy in XFG may be longer than that in POAG [78, 80, 81], and glaucomatous progression after filtering surgery may be slower in XFG patients compared to POAG patients [19, 81].

Although non-penetrating techniques rarely achieve sufficiently low IOP to defer progression in patients with an aggressive glaucoma like XFG, they may still be an attractive alternative in few selected patients due to their favorable safety profile [82, 83]. In a randomized trial that comprised both POAG and XFG patients intraoperative use of mitomycin C increased the effectiveness of deep sclerectomy [84]. Thirty-six months postoperatively the mean IOP in eyes operated with and without adjunctive mitomycin C was 15.96 ± 1.71 mmHg and 18.71 ± 2.90 mmHg, respectively ($P = 0.001$). In a retrospective study that contained data on XFG eyes, the efficacy of the newly developed technique of CO₂ laser-assisted deep sclerectomy was found comparable to that of conventional deep sclerectomy [85]. The complete success rates (IOP < 18 mmHg without medication) were 73% in the CO₂ laser-assisted group and 71% in the control group, respectively, whereas the total success rate (IOP < 18 mmHg with/without medication) was 96% in the CO₂ laser-assisted group and 89% in the control group. A prospective study conducted on 24 XFG and 25 POAG patients investigated the efficacy of deep sclerectomy combined with various space-maintaining implants [86]. With a mean follow-up period of 19.9 months for the XFG group and 16.2 months for the POAG group, the proportion of eyes with complete success

(IOP < 19 mmHg without medication) was 60.7% in the XFG group and 37.9% in the POAG group.

The available evidence on the efficacy of viscocanalostomy in eyes with XFG is limited. In a prospective, non-randomized case series comprising 57 glaucomatous eyes (14 of them had XFG) an IOP < 21 mmHg without medication was observed in 60% of eyes after 60 months following viscocanalostomy [87]. Recently the efficacy of concurrent phacoemulsification and viscocanalostomy in 30 eyes of 22 patients with cataract and poorly controlled XFG was investigated [88]. The mean preoperative IOP was 25.3 mmHg. After a mean follow-up period of 18.6 months, success (IOP < 21 mmHg with/without medication) was achieved in all eyes and complete success (IOP < 21 mmHg without medication) was achieved in 90% of the eyes. In a subsequent prospective trial the efficacy of phacoemulsification combined with viscocanalostomy was evaluated in cataract patients with medically uncontrolled XFG or POAG [89]. The mean preoperative IOP was 24.5 mmHg for the XFG group (n = 30) and 21.7 mmHg for the POAG group (n = 30). The mean follow-up period was 19.7 months for both groups. At the last postoperative visit the XFG patients had significantly lower IOP than the POAG patients (49.7% vs. 30.9% IOP reduction, respectively).

The recently developed technique of ab-interno trabeculotomy with the Trabectome™ (Neomedix Inc., Tustin, CA, US) has been approved for the treatment of open angle glaucoma. A 12 months, prospective, non-randomized study evaluated the outcomes of Trabectome™ surgery alone and in combination with cataract surgery and intraocular lens implantation in XFG and POAG eyes [90]. For the “Trabectome™ surgery only” analysis the preoperative IOP was 29.0 mmHg and 25.5 mmHg for the XFG (n = 67) and the POAG group (n = 450; $P < 0.01$), and the IOP decreased by 12.3 ± 8.0 mmHg and 7.5 ± 7.4 mmHg in the XFG and POAG group, respectively ($P < 0.01$). The cumulative probability of success for the XFG and POAG groups was 79.1% and 62.9%, respectively ($P = 0.004$). In the “combined Trabectome™ plus cataract surgery” analysis the mean preoperative IOP was 21.7 mmHg and 19.9 mmHg for the XFG (n = 45) and the POAG (n = 263) group ($P = 0.06$), and the IOP decreased by 7.2 mmHg and 4.1 mmHg in the XFG and POAG groups, respectively ($P < 0.01$). The cumulative probability of success for the XFG and POAG group was 86.7% and 91.0%, respectively ($P = 0.73$). The results suggest that ab-interno trabeculotomy offers superior IOP control in XFG compared to POAG.

Trabecular aspiration is a technique specifically developed for the treatment of XFG based on the notion that surgical removal of the exfoliation material and pigment granules deposited on the intra-trabecular spaces should enhance aqueous humor outflow [91]. In a prospective trial with 22 eyes of 19 patients with uncontrolled XFG the mean preoperative IOP on medication (31.3 mmHg) was significantly lowered to 16.8 mmHg 18 months after trabecular aspiration [91]. Following the procedure, 45% of the patients required no IOP lowering medication. In the same study, the authors evaluated the efficacy of trabecular aspiration combined with phacoemulsification or extracapsular cataract surgery in 42 eyes of 36 patients with uncontrolled XFG and cataract. For these eyes the mean preoperative IOP on medication (32.4 mmHg) significantly decreased to 18.7 mmHg 2 years after the combined procedure [91]. In this subgroup, 54% of the participants did not need medication at the end of the 2-year follow-up period. In another prospective, controlled study the same authors compared the efficacy of phacoemulsification, combined phacoemulsification and trabecular aspiration, and combined phacoemulsification and trabeculectomy on 74 non-operated eyes

with XFG and cataract [92]. Failure was defined as the necessity for additional surgical or laser interventions (except for laser suture lysis), or the need for more than one medication to reach an individualized target pressure. After a 2-year follow-up period the proportions of successfully treated patients in the phacoemulsification alone group, the combined phacoemulsification and trabecular aspiration group, and the combined phacoemulsification and trabeculectomy group were 36%, 64% and 78%, respectively. The proportions of medication-free well-controlled patients 2 years after the above procedures were 9%, 38% and 65%, respectively.

Cataract surgery is frequently necessary in XFG due to nuclear cataract induced by increased oxidative stress in the anterior chamber [28, 30, 33]. In addition, cataract surgery offers a clinically significant IOP decrease in XFG and XFS eyes with elevated IOP [93-96]. It has been suggested that the IOP-lowering effect of cataract extraction in eyes with XFG and XFS is due to a combination of the following mechanisms: widening of the anterior chamber angle, removal of a large portion of the exfoliation-producing anterior capsule, decrease of irido-lenticular friction (which limits the release of pigment and exfoliation material postoperatively), aspiration of deposited debris from the trabecular meshwork during surgery, and enhancement of the trabecular outflow as a consequence of low-grade inflammation (the hypothesized mechanism being similar to that seen after argon laser trabeculoplasty [14, 93]). In a 2-year, multicenter, prospective cohort study the IOP-lowering effect of phacoemulsification was assessed in 71 cataract patients with exfoliation (29 patients had XFG) and 112 without exfoliation [93]. Eyes with XFS and XFG had a significantly larger IOP reduction than POAG patients and non-glaucomatous controls. Remarkably, the investigators found that the ocular hypotensive effect of cataract surgery in the exfoliation group was associated with the volume of the irrigating fluid. This suggests that the IOP-lowering effect of cataract surgery can be attributed to the intraoperative removal of debris. The results of this prospective study fit well to earlier data from retrospective case series [94, 95]. In another retrospective study conducted on 1122 XFS and XFG eyes followed for 7 years, the postoperative IOP reduction was proportional to the preoperative IOP [96]. A recent retrospective study found that the proportion of XFS patients who converted to XFG after phacoemulsification within the more than 6-year long follow-up period was lower than expected, and the mean IOP of eyes with exfoliation at the end of the follow-up period was 2.6 mmHg lower than the mean preoperative value [97].

However, cataract surgery in XFS and XFG is associated with several disease-specific surgical challenges [14, 19, 98]. These include Zinn's zonule laxity and/or fragility, phacodonesis, lens subluxation or luxation, inadequate mydriasis, hard nucleus, fragile capsule and increased risk of vitreous loss. In the postoperative period common complications include corneal edema due to exfoliation-related endotheliopathy, transient IOP elevation, postoperative fibrinous inflammatory reaction (mostly after extracapsular cataract extraction), anterior capsule phimosis and delayed in-the-bag intraocular lens subluxation or luxation.

VASCULAR ALTERATIONS IN XFS

An association between XFS and systemic vascular dysfunction or even vascular disease (capillary, medium and large artery dysregulation, increased plasma homocysteine level,

increased arterial stiffness and reduced distensibility, abnormal baroreflex sensitivity and heart rate regulation, increased risk for venous occlusions and aortic aneurisms) has been shown in several, but not all, populations [51, 99, 100, 101]. The relationship between systemic vascular disease and XFS is independent from the presence of XFG. In XFS, retinal vein occlusion is a part of the systemic vascular abnormalities. Since management of the vascular diseases associated with XFS exceeds the scope of the ophthalmologist, consultation with the patient's cardiologist, internist or general practitioner, who cannot detect XFS, is necessary. The ophthalmologist needs to indicate that the patient has XFS, and that XFS may represent a special risk for systemic venous occlusions and vascular diseases, thus special attention and care may be necessary after the first signs of systemic vascular disease are detected.

UNMET NEEDS IN THE TREATMENT OF EXFOLIATIVE GLAUCOMA

Similarly to primary open-angle glaucoma, the current treatment of XFG entails IOP reduction. Though therapeutic measures to decrease IOP are essential for the successful long-term management of XFG, disease progression remains common even when both the treated long-term mean IOP is low and the between-visit IOP fluctuation is small [25]. As discussed earlier in this chapter, increased oxidative stress plays a key role in the IOP elevation in XFG [33]. Therefore decrease of oxidative stress in the anterior chamber of the eye would be a potential disease-specific treatment in XFG. Unfortunately, currently no such treatment or prevention option exists except for use of sunglasses during outdoor activity.

CONCLUSION

Since XFS is a common condition, and XFG is an especially severe, rapidly progressing and common secondary open-angle glaucoma, better understanding of the pathophysiological processes in XFS and XFG and establishing a disease-specific targeted therapy of XFG would be of great clinical importance. Currently XFS is not considered a disease to treat, but rather a genetically determined condition to observe for conversion to XFG. In contrast, XFG requires effective IOP lowering treatment which needs to be introduced early in the course of the disease to prevent progression. In XFG, IOP reduction is satisfactory when the diurnal IOP curve shows no high peaks but low mean value ($IOP < 17$ mmHg) and low fluctuation, the visual field does not progress or the rate of progression is small, and the patient is adherent to the successful treatment. Even in such cases regular ophthalmological examinations are unavoidable, and ophthalmologists need to know that due to the continuous synthesis of XFM and the gradual buildup of pigment in the trabecular outflow system there is always a risk of sudden loss of IOP control, and a need to introduce a more complex IOP lowering medication, laser therapy or surgery. Since XFG is a disease of the elderly it is important to simplify therapy using fixed dose combination eye drops and minimal number of daily instillations, thus supporting adherence. Consulting with a glaucoma subspecialist is also important when optimal IOP control is not achievable in XFG because unnecessary delay prior to surgery results in unavoidable disease progression.

ABSTRACT

Introduction: Systemic autoimmune disease is a multisystem IgG4-type fibroinflammatory syndrome that is characterized by high levels of IgG4 and IgG4 lymphoplasmacytic multifocal infiltration. IgG4-related cholangitis is the biliary manifestation of this disease and is characterized by biliary stricture and jaundice. It can

* Corresponding Author's Email: marcote15@yahoo.es.

appear as a unique manifestation or be associated with autoimmune pancreatitis before and after surgical treatment.

Objective: The objective of this study is to understand the impact of IgG4-related sclerosing cholangitis after hepato-biliary-pancreatic resection in our population and identify non-invasive diagnostic methods, IgG-IgG4 serum values, and magnetic resonance cholangiography (MRC) images to diagnose this entity in the early postoperative period in order to avoid aggressive and unnecessary treatment.

Material and Methods: The method used was a population-based case control study that included 109 patients who underwent liver resection. Biochemical and MRC images were obtained between the fifth and seventh postoperative days.

Parameters: Clinics: Age, sex, postoperative jaundice. Biochemicals: Total Bilirubin (BB), Alkaline phosphatase (ALP), Gamma Glutamyl Transferase (GGT), Immunoglobulin G (IgG), Immunoglobulin G4 (IgG4). Radiologic images: Magnetic Resonance (Philips Gyroscan Intera 1.5 T).

Results: The study included 109 patients were studied with a mean age of 59 ± 15 years. ALP: 142 ± 79 IU/L. BB: 1.5 ± 2 mg/dl. GGT: 188 IU/L. IgG: 948 ± 420 mg/dl (751-1560) mg/dl. IgG 4 ± 51 mg/dl (9-104) mg/dl.

Radiologic bile duct stenosis existed in six patients: In five patients, the stenosis was an intrahepatic stenosis, of which three cases were associated with postoperative collection, and in two patients, there was an image that was compatible with filling defects due to blood clots or residual stones. In other patients, extrahepatic biliary stenosis existed with an image compatible with a filling defect due to a blood clot or biliary lithiasis. There was no pathological elevation of IgG-IgG4 values in these patients.

There was a pathological elevation of IgG values in four patients, of whom only two patients presented elevated levels of IgG4, 397 mg/dl and 217 mg/dl, respectively. There was no relationship with clinical symptoms or pathological biochemical values.

Conclusion: In the early postoperative biliary complications, we should include bile leaks that cause edema, fibrosis, and secondary stenosis; ischemia by vascular injury; and surgical injury of the biliary system. According to our results and to the medical literature, we consider IgG4-related sclerosing cholangitis as a late postoperative complication. We should consider the involvement of another organ, usually the pancreas, to diagnose autoimmune cholangitis when there is a stenosis of unknown origin during the postoperative period.

Keywords: IgG4-related sclerosing cholangitis, postoperative stenosis bile duct, IgG4-related sclerosing disease

INTRODUCTION

In spite of improvements in hepato-biliary surgical techniques that have reduced biliary complications, early postoperative bile duct stenosis is still a serious problem that increases perioperative morbidity. Early complications include bile duct injury caused by erroneous sectioning or surgical clips and stenosis of the bile duct system due to ischemia because of injury to the hepatic artery and due to edema and fibrosis from bile leakage. Early cholangitis can also cause bile duct stenosis and late strictures. Some authors have referred to IgG4-related sclerosing cholangitis after surgery. They considered that surgical stress allowed for increased autoimmunity in patients with IgG4-related sclerosing disease [1-11]. It's important to reach an appropriate diagnosis of this entity as soon as possible in order to avoid late complications and/or unnecessary surgical treatment, but we don't know the early

postsurgical incidence. We can only see complications many days or even months after surgery.

We can suspect IgG4-related cholangitis in a patient with stenosis that is associated with other manifestations of IgG4-related diseases such as autoimmune pancreatitis. But, if IgG4-related cholangitis is the only autoimmune manifestation, we can only use biliary tract imaging that shows diffuse or segmental narrowing and elevated serum IgG4 values, greater than or equal to 135 mg/dl [1-4], as a probable preoperative diagnosis.

Our aim was to understand the value of magnetic resonance cholangiography findings and IgG4 serum values in the early postoperative period as screening tests for identifying IgG4-related sclerosing cholangitis.

IGG4-RELATED DISEASE (IGG4-RD) AND IGG4-RELATED CHOLANGITIS (IGG4-SC)

IgG4-related disease is a clinical entity that involves multiple organs, with an unknown etiology, but it is associated with infiltration of the organs by IgG4-positive cells. Organs with IgG4-related disease show diffuse or focal enlargement because of a great infiltration of lymphocytes, plasmacytes, and fibrosis. The organs can be affected synchronously or metachronously and include the pancreas, lacrimal glands, orbital soft tissue, eyes, extra-ocular muscle, salivary glands, pachymeninges, hypophysis, thyroid, arteries, mediastinum, retroperitoneum, mesentery, skin, lymph nodes, bile ducts, gallbladder, liver, lung, pleura, pericardium, kidney, breasts, and prostate.

The histopathological characteristics associated with IgG4-RD are a dense lymphoplasmacytic infiltrate, a storiform pattern of fibrosis, and an obliterative phlebitis. Other features that can appear include increased numbers of eosinophils and phlebitis without obliteration. But, the minimal criteria for diagnosis of IgG4-RD are the presence of elevated IgG4 plasmatic cells in the histopathological study, the existence of elevated IgG4 serum values, the effectiveness of glucocorticoid therapy, and the involvement of other organs.

IgG4-SC is a type of sclerosing cholangitis of unknown origin characterized by an intense infiltration of IgG4-positive plasmatic cells, obliterative phlebitis, and storiform fibrosis of the bile duct. These histopathological characteristics show a bile duct system with circular and symmetrical thickening of the bile duct wall.

The presence of infectious agents and autoimmunity are pathogenetic mechanisms in IgG4-SC. Interleukins 4, 5, 10, and 13 and TGF- β are overexpressed, and type 2 helper T (Th2) cells predominate. These cytokines allow for an elevated serum IgG4, IgE, eosinophilia, and fibrosis [12-15].

Definitive clinical diagnostic criteria of IgG4-related sclerosing cholangitis were established by the working group for this proposal in 2012 [1-3].

A diagnosis of IgG4-SC is realized using a combination of the following criteria:

- Biliary tract imaging revealing diffuse or segmental narrowing of the intrahepatic and/or extrahepatic bile duct. It exits thickening of the bile duct wall
- Elevated serum IgG4 concentrations, ≥ 135 mg/dl

- Coexistence of autoimmune pancreatitis and the involvement of other organs as dacryoadenitis, sialadenitis, and retroperitoneal fibrosis
- Histopathological findings: a) marked lymphocytic and plasma cells infiltration and fibrosis; b) infiltration of $\geq$ IgG4-positive plasma cells/HPF; c) storiform fibrosis; and d) obliterative phlebitis
- Option: Effectiveness of steroid therapy since we can't obtain sufficient tissue to study from multiple patients.

The definitive diagnosis includes a combination of the criteria:

1 + 3
 1 + 2 + 4a, 4b
 4a, 4b, 4c
 4a, 4b, 4d

The incidence of IgG4-SC is unclear because of the very small number of references in the medical literature that include only solitary centers, with few patients, and we don't know for sure if the associated stenosis of autoimmune pancreatitis (AIP) is due to lymphoplasmacytic infiltration or infiltration of the pancreas without bile duct thickness.

In Japan, the incidence of IgG4-RD is 0.28-1.08/100.000, with a prevalence of 336-1300 newly diagnosed patients per year. In eastern countries, autoimmune pancreatitis appears in 6% of the population. In western countries, the occurrence has been described in 11% of patients. In Japan, 75.9% of the patients with AIP show associated sclerosing cholangitis. In eastern countries, 26.6% of patients have a diagnosis of IgG4-SC not associated with AIP, and in western countries, the incidence is 8% [16-23]. Some authors [19, 21, 22] have referred the incidence of IgG4-SC with respect to benign hilar strictures that have been resected. They found an incidence level between 4.8% and 9.1%. Using our magnetic resonance cholangiography findings and IgG4 serum values in the early postoperative period, we didn't find any patients with IgG4-SC.

IGG4-RELATED SCLEROSING CHOLANGITIS AFTER SURGERY

In 2005, our group presented a patient who, after duodenopancreatectomy due to a lymphoplasmacytic pancreatitis pseudotumor, was admitted to our department because of obstructive jaundice at 75 days after surgery. At admission, the patient showed an elevated serum IgG value of 1520 mg/dl but a non-elevated serum IgG4 value of 28 mg/dl. Magnetic resonance cholangiography revealed dilatation of the intrahepatic biliary tract with no visualization of the hilar plate or the common bile duct. The case was resolved using methylprednisolone [5]. Wallis de Vries et al. [6] also reported a patient who presented with extensive stenosis of the intrahepatic biliary system after pancreaticoduodenectomy and was successfully treated using steroids. Marrache et al. [7] described three patients with severe cholangitis following pancreaticoduodenectomy. The three patients showed stenosis of the intrahepatic biliary system and the common bile duct. Only one patient presented with elevated IgG and IgG4 serum values.

CDP: Cephalic Duodenopancreatectomy. PPCDPC: Pylorus Preserving Cephalic Duodenopancreatectomy. AIP: Autoimmune Pancreatitis. IHBD: Intrahepatic Biliary Duct. EHBD: Extrahepatic Biliary Duct. CBD: Common Biliary Duct.

In 2006, Schmassmann et al. [9] presented a patient who had been readmitted six weeks after pancreaticoduodenectomy due to jaundice. MR imaging showed intra and extra bile duct strictures, but the IgG4 serum values were normal. In 2009, Alderlieste et al. [8] described a patient with reoccurring jaundice after a Whipple procedure and abnormal IgG and IgG4 serum values. A diagnosis of stenosis and dilatation of the bile duct system was made in this case by percutaneous transhepatic cholangiography.

In 2010, we added a patient with jaundice after hepatic resection. In this patient, magnetic resonance imaging showed intrahepatic bile duct system stenosis. The serum values of IgG were elevated at 2060 mg/dl but the IgG4 serum values were normal at 37 mg/dl [10]. Ramia et al., [11] in 2011, described a male patient with cholangitis 24 months after hepatojejunostomy. MR imaging showed intrahepatic biliary duct system stenosis. In this case, the patient presented with elevated IgG4 serum values, 353 mg/dl. In all the cases, the sclerosing cholangitis appeared as late complications after surgery. For this reason, our aim was determining the value of magnetic resonance cholangiography (MRC) findings and IgG4 serum values in the early postoperative period after hepato-biliary-pancreatic surgery.

CASE-CONTROL STUDY PERFORMED BY OUR GROUP

We decided to perform a prospective study to determine the value of magnetic resonance cholangiography findings and IgG4 serum values in the early postoperative period after

hepato-biliary surgery, with the possibility of using them as screening tests for identifying IgG4-related sclerosing cholangitis. This was a population-based case control study that included 109 consecutive patients, operated on in our department by means of a liver resection that included at least two anatomical liver segments. We performed selective vascular exclusion before parenchyma resection. After resection, an intraoperative cholangiography was performed to provide a description of a normal bile duct system. A magnetic resonance cholangiography was performed in all patients on the seventh postoperative day. If pathological images were found, a percutaneous cholangiography and/or a retrograde endoscope cholangiography were performed for diagnosis and treatment, if possible. A serum sample was obtained from each patient on the seventh postoperative day for measuring the IgG4 values. Written informed consent was obtained from all patients. Those patients who refused to be included in the study, unstable haemodynamic patients, and claustrophobic patients were excluded.

Clinical diagnostic criteria of IgG4-related sclerosing cholangitis were established by the working group for this proposal in 2012 [3].

1. Biliary tract imaging revealing diffuse or segmental narrowing of the intrahepatic and/or extrahepatic bile duct. It exists thickening of bile duct wall
2. Elevated serum IgG4 concentrations, ≥ 135 mg/dl
3. Coexistence of autoimmune pancreatitis, dacryoadenitis, sialadenitis, and/or retroperitoneal fibrosis
4. Histopathological findings: marked lymphocytic and plasma cells infiltration and fibrosis; infiltration of $\geq$ IgG4-positive plasma cells/HPF; storiform fibrosis; And obliterative phlebitis
5. Option: effectiveness of steroid therapy

For our study, a possible diagnosis would include the diagnostic items 1 and 2.

Clinical and biochemical parameters: · Age (years), sex (male/female), and pathological specimen diagnosis · Liver parameters that were obtained on the seventh postoperative day were BB (mg/dl), ALP (IU/L), and GGT (IU/L). · On the seventh postoperative day, serum samples were obtained and stored at -20°C for the measurements of IgA, IgM, and IgG subclasses. They were analyzed by a turbidimetric protein analyzer (SPAPLUS®). We used 135 mg/dl [1-4] as the serum IgG4 cut-off value for differential diagnosis.

Magnetic resonance imaging (MRI): All the patients fasted for six hours prior to the procedure, and images were obtained during apnea. MRI imaging was performed with a 1.5-T clinical imager (Philips Gyroscan Intera 1.5 T), on the seventh postoperative day. Patients were placed in a supine head-first position.

1. Multiplanar acquisition (axial, sagittal, and coronal images). Parallel images (SENSE)
2. T1 - GE. Axial. Cranial and caudal parallel saturation bands

We used sequences that were T2 weighted to depict fluid-containing biliary ducts. We also included half-fourier acquisition single-shot turbo spin. echo, HASTE.

T2 - S S h (HASTE) coronal. section thickness of 5 mm.

T2 - S S h (HASTE) axial section thickness of 5 mm.

T2 - TSE – Projection images. Section volumen of 50 mm. We obtained several slices (at least four), coronals, and coronal oblique planes, placed over an axial plane that includes the field of bile duct.

Image analysis: Images from MR cholangiography were viewed by three observers. Stricture was defined as the narrowing of the bile duct that explains abnormal and cholestatic liver parameters and a ductal caliber change. Intrahepatic and extrahepatic bile duct dilatation is defined as a diameter greater than 2 mm and 7 mm, respectively.

Classification of cholangiographic findings of IgG4-related sclerosing cholangitis: type 1. stenosis located in the lower part of the common bile duct; type 2. stenosis in the intra-hepatic and extra-hepatic bile ducts; type 3. stenosis in the hilar and the lower part of the common bile duct; type 4. hilar hepatic stricture [1].

Results: 109 patients were studied with a mean age of 59 ± 15 years old (range from 18 to 86 years old), being female patients in 55 cases. The biochemical values were: ALP: 142 ± 79 . BB: 1.5 ± 2 . GGT: 188. IgG: 948 ± 420 mg/dl, normal range (751-1560). IgG 4 ± 51 mg/dl, (15-198), normal range (9-104). IgG1: 538 ± 323 mg/dl (122-2080). IgG2: 318 ± 177 mg/dl, (100-1130). IgG3: 64 ± 39 mg/dl (15-198). IgA: 258 ± 150 mg/dl (44-852). IgM: 132 ± 103 (184-439).

Pathological diagnosis of the resected specimens were:

Hepatocarcinoma, 6(5.5%). Cholangiocarcinoma, 5(4.6%). Colorectal hepatic metastasis, 41(37.6%). Non endocrine, non colorectal hepatic metastasis, 12(11%). Hemangioma, 2(1.8%). Nodal focal hyperplasia, 1(0.9%). Hepatic sarcoma, 1(0.9%). Hepatic hidatidosis, 25(22.9%). Gallbladder cancer, 12(11%). Hepatic cyst, 2(1.8%). Liver adenoma, 1(0.9%). Endocrine liver metastasis, 1(0.9%).

Radiologic stenosis of bile duct existed in six patients. In five of the patients there was an intrahepatic stenosis. In three cases, the stenosis were associated with postoperative collection. In two patient there was an image that was compatible with defect of filling by blood clot or residual stones. In the other patient existed extrahepatic biliary stenosis with a compatible image showing a filling defect by blood clot or biliary lithiasis. IgG and gG4 values were no pathological in these patients.

There was a pathological elevation of IgG values in only four patients, with a range from 1670 to 3210 mg/dl. However only two patients presented elevated levels of IgG4, 397 mg/dl and 217 mg/dl, respectively. There were not relation with clinical symptoms or pathological biochemical values in the four patients.

MAGNETIC RESONANCE CHOLANGIOGRAPHY (MRC)

This is a noninvasive radiologic method for diagnosing bile duct complications that is less time consuming and associated with less morbidity than endoscopic retrograde cholangiopancreatography (ERCP) and percutaneous transhepatic cholangiography (PTCH). MR cholangiography can also control the biliary duct above and below the level of obstruction.

One of the complications after surgery is a bile duct stricture that is defined as a narrowing of a focal segment of the bile duct that leads to a proximal biliary dilatation, more than 3 mm in the intrahepatic bile duct system and more than 7 mm in the extrahepatic bile duct system, and clinical characteristics of obstructive jaundice. An inflammatory response due to injury is the causing of collagen deposition, fibrosis, and later the formation of a bile duct stricture. In our hypothesis, we think that the surgical stress, the injury, and/or a secondary infection after surgery can allow, in some patients, an autoimmunity process with severe lymphoplasmacytic cells infiltration in the bile duct system and secondary bile duct stenosis. For this reason, we need to identify the start of the process in order to solve it.

Early complications after surgery that can be easily diagnosed by MRC include lithiasis retention, hemorrhage, hemobilia, bile leaks, bile duct injuries from excision or ligation, and bile collection. Strictures are the most common of the late complications.

In our patients, a radiologic bile duct stenosis existed in six patients. In five of the patients, there was an intrahepatic stenosis. In three cases, the etiology of the stenosis was a postoperative collection. In two patients, there was an image that was compatible with a filling defect due to a blood clot or residual stones. In the other patient, extrahepatic biliary stenosis due to a blood clot or biliary lithiasis existed. IgG and gG4 values were not pathological in any of these patients.

MR cholangiography can be useful to analyze the anatomy of the biliary system and to detect bile duct complications such as stenosis. Some authors [24-32] propose radiologic features to diagnose IgG4-SC as common bile duct wall thickness greater than 2.5 mm, continuous involvement of the biliary system, absence of hepatic parenchymal complications, and gallbladder involvement. But, for a true diagnosis of IgG4-SC, we need to realize a combination with other diagnosis criteria.

IGG4 SERUM VALUES

Since 2001, serum IgG4 values equal to or greater than 135 mg/dl have been widely used for diagnostic criteria of IgG4-related sclerosing cholangitis and discriminating from other pancreatic diseases [33-39]. Hamano et al. [39] reported with these values a high accuracy, 97%, sensitivity, 95%, and specificity, 97%, for identifying AIP with respect to pancreatic cancer.

In 2012, elevated serum IgG4 concentrations, ≥ 135 mg/dl, were used as Japanese clinical diagnostic criteria. However, this cutoff in IgG4-SC shows a lower specificity for diagnosis IgG4 with respect to cholangiocarcinoma [33-39]. Some cases of primary sclerosing cholangitis, 9%, and pancreatic cancer, 10%, also show high levels of serum IgG4 values. In a multicenter study in Japan, it was considered that a cutoff four times the upper limit of the normal serum values of IgG4 could be 100% specific for IgG4-sclerosing cholangitis. This cutoff is also used in western centers. They also described that values of $\text{IgG4} \geq 207$ mg/dl can diagnose types 3 and 4 IgG4-SC [36].

CONCLUSION

According to our results and to the medical literature, we should consider IgG4-related sclerosing cholangitis as a late postoperative complication. When there is the involvement of another organ, which is usually the pancreas, we should suspect a diagnosis of an autoimmune cholangitis, IgG4-SC, when there is a stenosis of unknown origin in the postoperative period.

BIOGRAPHICAL SKETCH

David Padilla-Valverde, MD, PhD

Affiliation: Head of Section of Digestive and General Surgery. Department of Surgery. University General Hospital, Ciudad Real, Spain

Chief of Traslacional Research Unit, University General Hospital, Ciudad Real, Spain

Professor of Surgery. Faculty of Medicine, Castilla La Mancha University, Spain

Education: Grade of Medicine and Surgery, Medicine Faculty, Autonoma University, Madrid 1987-1993

PhD University, Year:

Medicine and Surgery, Medicine Faculty, Autonoma University, Madrid 1995-1997.

Medicine and Surgery, University of Cordoba, Spain 1998-2001

Address:

University General Hospital, Ciudad Real, Spain

Avd Obispo Torija s/n

13005 Ciudad Real, Spain

Research and Professional Experience:

- “Test of safety and effectiveness in hemodynamic monitoring, fluid and drug distribution during the development of a model of laparoscopic access for cytoreductive surgery and hyperthermic intra-abdominal chemotherapy through a closed recirculating CO₂ in a porcine experimental model system” Foundation Eugenio Rodriguez Pascual, 2014. PI: David Padilla.
- Usefulness of hyperthermic chemotherapy using intraabdominal gemcitabine for inhibiting tumor progression in an experimental model of pancreatic peritoneal carcinomatosis, and their behavior respect to CD133 + CXCR4 + cancer stem cells. Fundacion Eugenio Rodriguez Pascual. Madrid 12/26/2012. PI: Dr David Padilla.
- FIS Project of Health Research, Institute of Health, Carlos III, Madrid, Spain. 2011. “Value of 18-FDG-PET-CT with intravenous contrast in the post-neoadjuvant restaging of patients with liver metastases” PI: Dr Ana Garcia Vicente.
- Development of independent clinical research, Department of Pharmacy and Health Products of the Ministry of Health, Social and Equality Policy. SAS/2377/2010 and SAS/2039/2009. “Intraperitoneal chemohyperthermia closed with paclitaxel in the treatment of ovarian carcinomatosis” PI: Dr Pedro Villarejo.
- Project of Health Research. Foundation for Health Research in Castilla La Mancha (DOCM No 124 of 16 June 2008): “Analysis of the prognosis - therapeutic utility of serum determination by polymerase chain reaction, PCR, and histologically by in situ, FISH, miR-21, microRNA21 in patients with colorectal cancer” (number PI-2008/16) hybridization PI: Dr David Padilla.
- Project: Gedi (Global Volume Diastolic) Versus PVC (Central Pressure Vein) In Control Blood Loss During Liver Resection Of Colorectal Metastasis who have received preoperative chemotherapy. IP: Dr Javier Redondo Calvo. Funding by Mutua Madrileña, Madrid, Spain. PI: DR Javier Redondo. 2013.
- “Selected advanced therapy for ovarian cancer using isolation, diagnosis and treatment of CD133 + CD44 + ovarian cancer stem cells after intra-abdominal cytoreductive surgery and closed recirculation with CO₂ chemotherapy.” Funding by AMUMA, Ciudad Real, 2014. PI: David Padilla-Valverde.
- “Individualized therapy in ovarian and pancreatic cancer by isolation, diagnosis and treatment of cancer stem cells after cytoreductive surgery and intraabdominal

chemohyperthermia closed recirculating with CO₂ chemotherapy.” Funding by Roche Fundacion. 2014-2015. PIs: David Padilla-Valverde/Pedro Villarejo-Campos.

- Research project: “Technical and functional validation in animal model PRS equipment for treatment of peritoneal chemo-hyperthermia.” 2009-2011. Departament of Animal Medicine and Surgery Autonomous University, Barcelona. Funding by: Biosurgical, SL. 2011.PI: Alberto Martinez.
- Research project: “Technical and functional validation in an animal model of the PRS equipment for chemo-hyperthermia bladder treatment.” 2009-2011. Departament of Animal Medicine and Surgery. Autonomous University. Funding by: Biosurgical, SL. 2011. PI: Alberto Martinez.
- Principal co-investigator of the International LiverMetSurvey Project “Multidisciplinary treatment of colorectal liver metastases,” 2007-2012. Funding by: Safonis Aventis. PI: Dr René Adams. 2007-2013.

Professional Appointments:

Line Cancer Research

- Co-principal investigator of the International Project, “LiverMetSurvey” “Multidisciplinary treatment of colorectal liver metastases,” 2007-2016.
- Development of an Hipec Model for performing chemohyperthermia in patients with peritoneal carcinomatosis of gastrointestinal and ovarian origin.
- Development of filter systems for the isolation and treatment of tumor stem cells in drug recirculation during chemohyperthermia.
- Comprehensive Program, bi-directional and individualized treatment to improve the prognosis of tumors in advanced stage. Our group has technical and human resources to implement everywhere, everytime, an individualized program for patients with advanced pancreatic, bile duct, colorectal and ovarian cancer. We will perform surgical treatment, isolation, identification, characterization and tumor stem cell culture, by the use of locoregional chemohyperthermia.
- Research project: “Technical and functional validation in animal model of a PRS equipment for treatment of peritoneal chemohyperthermia.” Department of Animal Medicine and Surgery. Autonomous University of Barcelona.
- Creation of the patent “recirculation system for hyperthermic perfusion and intra-abdominal chemotherapy, GST COMBAT PRS, Peritoneal QHT Team, GALMAZ SL” in a porcine model of peritoneal carcinomatosis (2009-2014).
- Development of a utility model for development of chemohyperthermia in patients with bladder cancer. Research project: “Technical and functional validation in animal model BRS bladder treatment equipment chemohyperthermia” (2009-2014). Department of Animal Medicine and Surgery. Autonomous University of Barcelona.
- Creation and development, of a murine model of peritoneal carcinomatosis with pancreatic neoplastic cell line, therapy with cytoreductive surgery and with intra-abdominal chemohyperthermia closed. Traslational Research Unit, Surgery Department and Laboratory Department of University General Hospital, Ciudad Real, Faculty of Medicine, UCLM.

Preclinical Development of anti-inflammatory and anti-cancer functionality of new synthetic products in collaboration with the, Castilla-La Mancha university, UCLM.

- “Treatment Of Sepsis And Septic Shock By Allicin (AJO Lyophilisate) + Black Garlic, as an adjuvant treatment to antibiotic treatment in An Experimental Model Of Bacterial Peritonitis.”
- Allicin (AJO Lyophilisate) + Black Garlic As *In Vitro* Growth Inhibitor of cell lines colon carcinoma.
- Allicin + Black Garlic and Alterations of epithelial barrier function. Translational Research Unit and Surgery Group, HGUCR, Ciudad Real, Spain.

Implementation and Development of New Surgical Techniques

- Development and implementation of a program of cytoreductive surgery + HIPEC in ovarian and colon carcinomatosis.
- Developing a program of laparoscopic access Hepatobiliopancreatic Surgery (2009-2016).
- Developing a monitoring program of selective control of liver reserve in a model of volume restriction in liver surgery (2009-2016).
- Setting up a program of autologous islet Lagerhans transplant for patients with benign or malign pancreatic resection.

Agreements, Technological Merits

- Agreement between the Foundation “Mutua Madrileña” and the University General Hospital of Ciudad Real to promote collaboration in research, funding the study: GEDI (Global Volume diastolic) versus PVC (Central Pressure Vein) In Control Blood Loss During Liver Resection Of Colorectal Metastasis who have received preoperative chemotherapy PI: Dr Javier Redondo Calvo.
- Agreement between the Technology Institute of Environmental Chemistry (ITQUIMA), University of Castilla La Mancha and Translational Research Unit of the General Hospital of Ciudad Real. PIs: Dr. Javier Redondo, Dr. David Padilla, 2014-2016.

Patents

- Creation of an utility model “System for hyperthermic perfusion and recirculation intra-abdominal chemotherapy, GST COMBAT PRS, Peritoneal QHT Team, Galmaz S.L.” porcine model of peritoneal carcinomatosis, 2008-2011, Faculty of Veterinary Medicine, Autonomous University, Barcelona. PI: Alberto Martínez Albalat/Dr Pedro Villarejo/Dr David Padilla.
- “Fluid Recirculation System,” PCT/EP2011/006617 Biosurgical S.L. Creation and development of the patent “Agitation Apparatus” in a pig bladder carcinomatosis model, 2008-2011, Faculty of Veterinary Medicine, Autonomous University, Barcelona. PI: Alberto Martínez Albalat/Dr Pedro Villarejo/Dr David Padilla. “Agitation Apparatus,” 1,220,306.

Others

- International Research Fellowship, Trauma Surgery and Intensive Care. Medical Center, University of Southern California. Los Angeles, California. 1998.
- International visitor, Liver Transplant Surgery Hepatobiliary and Pancreatic Surgery and, Department of Surgery. Queen Medical Hospital, Hong Kong.
- “Master in Medical and Clinical Management” (UNED), Spain. 2007-2009.
- Category C for the handling of animals used for experimental and other scientific purposes.

Current Development of Clinical Trials

- “GEDI (Global diastolic volume) versus PVC (Central venous pressure) in the control of blood loss and perioperative morbidity during liver parenchymal transection by hepatic neoplasms.” PI: Dr Redondo Calvo.
- “Chemohyperthermia closed intraperitoneal paclitaxel in the treatment of ovarian carcinomatosis” No. EUDRACT: 2011-006319-69. PI: Dr Villarejo Campos.
- “Multicenter, randomized trial to evaluate the adjuvant effect of HIPEC-mitomycin C associated with surgery versus surgery alone in the T4 colorectal cancer.” Colorectal carcinoma study. PI: Dr Sebastian Peña Ruffian.

Participation in Committees and Working Groups

- Working Group of Perioperative Medicine (2010-2012)
- Tissue Tumors Commission (2007-2011)
- Research Commission (2009-2011)
- Multidisciplinary Committee of digestive tumors (2007-2012)
- Coordinator of the Translational Research Unit, ITU, HGUCR, 2014-2016.
- Animal Experimentation Ethic Committee, HGUCR 2016 ·Member of Spanish Surgeon Society

Honors

- Top 20 awards, General Surgery and Digestive Diseases. Hospital Complex, Ciudad Real. Health and Consumer Affairs Ministry, 2004.
- Award for Best Scientific Communication in Medicine, “Angiogenesis and lymphangiogenesis in gastric cancer,” presented at the XXI National Meeting of the Spanish Chapter of the ISDE (Madrid, April 2009).
- 2005 “Research projects Fiscam Award,” “Serum growth factor of vascular endothelium in patients with colorectal cancer and its prognostic significance.” 2005.
- Golden badge for David Padilla Valverde, as a member of hyperthermia Group, University General Hospital, Ciudad Real.
- Best Oral Communication Award, XVII National Meeting of the Spanish Association of Coloproctology, Mallorca, 2013, “Prognostic Utility of serum determination of microRNA-21 in patients with colorectal cancer functions.”
- Prize for the best publication in 2013 in HGUCR: Villarejo-Campos P, D Padilla-Valverde, Martín RM, Menedez-Sanchez P, Cubo-Cintas T, Bondia-Navarro JA, Martín J. Serum VEGF and VEGF-C values before and after surgery postoperative treatment in gastric cancer. *Clin. Transl. Oncol.* 2012.

- “Dionisio Daza Chacon Award,” 2013, for the study: Menendez p, Villarejo P, D Padilla Menendez JM, JA Rodriguez-Montes. “Diagnostic and prognostic utility of microRNA-21 in colorectal cancer.” 2013.
- Best research work in health, University General Hospital, Ciudad Real, 2014, Development Of An Experimental Intraabdominal Chemohyperthermia Model With Closed Technique And CO₂ Recirculation System By Means Of Combat @ PRS-I.0.
- Accesit best oral communication “Utility of hyperthermic intra-abdominal chemotherapy by gemcitabine for inhibiting tumor progression in an experimental model of pancreatic peritoneal carcinomatosis, concerning their behavior with CD133 + CXCR4 + cancer stem cells.” Biomedicina 2014, Ciudad Real, HGUCR, Spain.
- Accesit to best oral communication, “Utility of hyperthermic intra-abdominal chemotherapy by gemcitabine for inhibiting tumor progression in an experimental model of pancreatic peritoneal carcinomatosis, concerning their behavior with CD133 + CXCR4 + cancer stem cells.” XX National Meeting of the Spanish Association of Surgeons, Granada 2015.
- Best communication, “Utility of hyperthermic intra-abdominal chemotherapy by gemcitabine for inhibiting tumor progression in an experimental model of pancreatic peritoneal carcinomatosis, concerning their behavior with CD133 + CXCR4 + cancer stem cells.” IV National Congress of Surgical Oncology. SEOQ. Madrid, 2015.

Chapter 431

THE IMPACT OF SOCIAL MEDIA IN MEDICINE: AN EXAMINATION OF ORTHOPAEDIC SURGERY

²Orthopaedic & Rheumatologic Institute, Cleveland Clinic Foundation,
Cleveland, OH, US

ABSTRACT

In medicine, the potential of social media is vast from a population health standpoint but limited by the concern of patient privacy. Orthopaedic surgery serves as an excellent case within medicine for its high volume, elective nature, less sensitive patient privacy concerns, and glaring need for patient reported outcomes. Furthermore, this increasingly popular modality serves as a revealing instrument for surveying the marketplace landscape, including hospital and surgeon perspective, to the end of characterizing and quantifying “word of mouth” effects in medicine as the health care economy becomes increasingly consolidated and competitive. Ultimately, the insights gained through our social media analysis of orthopaedic surgery may be applied to better understand and improve patient-perceived outcomes in all subspecialties of medicine and surgery.

Keywords: social media, orthopaedic surgery, outcomes

INTRODUCTION

Within the last decade, social media has exploded on the scene with the advent of continuous connectivity to web-based content and the popularization of mobile devices. Integrative platforms including Facebook, Twitter, and Instagram have invited users to

* Corresponding Author's Email: premrakumar@gmail.com.

connect online and readily publish content that includes their opinions and personal experiences. Initially used as a tool for individuals to connect with their personal networks, the rapid and broad adoption has facilitated the “small data” of individual social media content to be collected and analyzed as “big data.” Many firms currently employ dedicated social media teams within their marketing department to gather and publish data as a way of readily engaging consumer bases and adapting to changing demands. In medicine, the potential of social media to provide population health data is vast but must be cautiously approached due to the concern of patient privacy and Health Insurance Portability and Accountability Act (HIPAA) regulations.

The subspecialty of orthopaedic surgery serves as an excellent case study for the power of social media within medicine for its high volume, elective nature, less sensitive patient privacy concerns, and glaring need for patient reported outcomes. Our studies have surveyed available social media channels primarily in the context of the orthopaedic patient for various injuries and deformities to arrive at generalizable conclusions that can be adapted to better meet patient expectations. In this chapter, we investigate the frequency, content, and value of the organic social media posts to the delivery of health care in the context of the patient, surgeon, and hospital in orthopaedics.

OVERVIEW OF SOCIAL MEDIA

The potential for the orthopaedic field to benefit from utilizing social media begins with understanding current social media platforms and the extent of their usership. In a 2016 article published by the New York Times discussing social media habits, it was reported that the average American has 5 active social media accounts and spends an average of 1 hour and 40 minutes a day browsing these sites [16]. Facebook continues to be the most popular of these social media platforms with a usership of 68% of adult Americans. Users reportedly spend an average of 50 minutes a day scrolling through newsfeeds, profiles, and posted photos or videos. While Facebook usage remains far ahead of that of other social media platforms, as the millennial generation expands their interest in social media, popularity of other social forums is surging. For example, 81% of millennials check Twitter at least once a day and 32% of the younger generations report that Instagram is the most important social media platform [7]. Twitter became popular for its novel concept of allowing users to share brief pieces of inconsequential information in a time sensitive manner, and now many rely on Twitter for major real-time news updates and events. In 2007, Twitter added the hashtag (#) feature because users wanted a way to be able to connect and interact with each other in groups regarding a specific topic. While Twitter executives did not want to divide the platform into groups, they did see potential in adding context to users’ posts. By including a hashtag in a tweet, content may be filtered into groups based on shared context. Hashtags provide meta data for a twitter post, allowing users to access more information about current events and news both locally and worldwide. Because hashtags can be created and applied by any user, they have evolved into an effective way to follow any topic or conversation in real time.

As social media usership continues to increase, businesses have identified ways to tap into media platforms as a marketing approach. In 2016, over 50 million businesses were a

part of Facebook Business Pages and at least 2 million businesses use Facebook directly for advertising [7]. Facebook combines users' habits and interests to provide targeted advertising. This results in a powerful network for marketing that businesses are beginning to take advantage of. Besides directly using social media for advertising, businesses use the platform to share information about new additions to their services or as a platform for testimonials from clients. Social media can also provide businesses with valuable insight free of charge from potential consumers in real time about products, brands and services. In the past, firms would pay a substantial price for outside consulting agencies to provide such data from focus group interviews and surveys.

It is important to note that social media is ever changing. Ten years ago, providing content that could be rapidly disseminated to friends and family was the primary goal as Facebook developed the "status" and allowed photos or videos to be instantaneously shared with friends. Five years later, Instagram rose in popularity with the advent of photo and video-sharing through the use of photo editing with filters that glorify reality. Today, Snapchat and live streaming alternatives such as Facebook Live and Instagram Story are facilitating real-time unedited footage directly from a smartphone camera. According to survey data, in 2017, 43% of social media platforms plan to extend their content to include live streaming, up from 14% in 2016 [7]. The content of these live streaming events is difficult to quantify as yet but represent new potential for capturing patient satisfaction and attitudes.

Patient Report Outcomes in Orthopaedic Surgery

Due to the increased cost and heavily elective nature of the field, orthopaedic surgery is under immense administrative scrutiny over outcomes. However, there is currently no perfect criteria to establish how effective, successful, or valuable a procedure is. Surgeons are instead relying on outcomes reported from patient to justify the benefits and costs of the rising demand for most orthopaedic procedures. These patient reported outcome measures (PROMs) are widely used in orthopaedics in an attempt to quantify the success of procedures. However, in a systematic review of 38 studies reporting on 47 different PROMs by Ramkumar et al., it was concluded that only 6 out of 38 surveyed studies acknowledged all of the "gold standard" metrics [13]. It is clear that a single, validated, reliable PROM including all of the "gold standard" measurements does not yet exist for orthopaedic procedures. Because no perfect functional measure exists, orthopaedic surgeons need an outcome metric that has both functional and subjective components. However, one of the limitations with the subjective PROM component is the difficulty of obtaining the data in a reliable and anonymous manner rather than a physician-administered measurement.

Thus far, the PROM has been one of the most successful assessments based on factors important to the patient's experience. A review study published by Nelson et al. reported that systematic use of PROMs led to enhanced communication and decision-making between patients and their physicians [10]. A large randomized trial across more than 20 primary care practices of 1,651 patients examining patient self-assessment data showed the use of PROMs improved the quality of interventional care received. Patients in this study reported that they felt their care had improved over the 2-year course of the assessment and that their doctors invested more time in interventional care [17]. Despite the perceived success of the PROMs,

they have some key limitations. Because patient outcomes are reported on a monitored health care platform, some patients may feel limited in their ability to be honest regarding their attitudes towards their physician experience. In addition, PROMs represent interval, not continuous, data that can be easily influenced by the attitude or mood of the patient at a given moment.

Role of Social Media in Orthopaedics

Social media platforms may offer unique insights into the patient perspective. Historically, word of mouth that has comprised physician referrals basis has occurred offline. Now, patients are rating and evaluating their doctors and surgeries publicly online. Given the complexity of medicine and health care, the gap between physicians' impressions of a patient's condition and the patient's own understanding of their conditions can be a barrier to satisfactory patient care. The healthcare community has recognized this disparity and attempted to address it with the advent of metrics that assess factors important to the patient's care. In addition, administration has begun to tie these patient satisfaction scores via the Press Ganey survey to physician and institution reimbursement [1,2]. Orthopaedic surgery, in particular, is challenging since establishing a satisfactory or ideal outcome remains difficulty to quantify and patient-dependent.

Social media analysis of patient posts can address some of the limitations of PROMs. First, given the nature of personal social media accounts to revolve around personal daily life activities, patients may feel more compelled to share honest opinions about their surgeries or their opinions of their physicians. Because platforms such as Instagram and Twitter were created for the purpose of sharing experiences, members of younger generations rely on these to connect with other members of their community. Physicians and healthcare organizations, limited by time and resources, could benefit from the virtual connections to patients through social media outlets. One study reported that patients feel more connected to their health care providers when their provider is accessible via a professional social media account [3]. In addition, the results of our forthcoming analysis in orthopaedic surgery show that patients most often use social media to document their personal priorities and outcomes.

While social media content analysis lacks full capacity to evaluate an orthopaedic intervention, it allows for quantification of benefit in ways that standard measures cannot. It can aid in establishing a mean timeline at which other patients undergoing the same surgery can expect to recover. Our analytical process of patient-centered social media posts provides the medical community with a novel way to measure the social media impact and perceptions of orthopaedic injuries and surgical intervention outside of the tradition PROM metrics. Additionally, social media analysis can be used to indirectly measure outcomes globally. The Global Social Media Impact Study sponsored by University College of London is investigating the use of social media in different countries across a 5-year span. The preliminary data reports that there is a stark difference in the content of various countries' social media posts. Some countries' social media usage focuses on economics by using social media to promote and sell clothing or home goods. Other countries primarily use social media as a means of news communication [5]. The variety of social media usage expands to health care consumption as well. For example, the UAE focuses on a patient-centered approach compared to the UK's universal health system [5]. These differences in health care delivery

have been identified by examining social media usage. In our work using social media outlets, we gained an improved understanding of patients, hospitals, and surgeons across various interventions and surgeries.

Social Media Methodology

Our research employs multimodal approaches to analyze data across social media platforms to assess the frequency and perspective from orthopaedic patients, surgeons, and hospitals. Analyses of published content on Instagram and Twitter by way of hashtag search represent a new method of gathering patient-reported outcomes with a unique firsthand view of unbiased patient attitudes that may corroborate or add to PROMs research. This analytical process provides the medical community with a novel way to prioritize how patients evaluate their recovery from orthopaedic surgery and share their care with the people they know. In a way, social media is able to capture the “word of mouth” effects that have historically generated referrals.

Filtering the public domain of Instagram and Twitter posts using relevant orthopaedic hashtags allows for a collection of a population of content referencing orthopaedic procedures, surgeons, and outcomes. After filtering for posts that featured only human subjects and referenced orthopaedics and musculoskeletal injuries, the authors were able to assess patient opinions and outcomes pre- and post- operatively. A categorical scoring system was used to analyze for the following: media perspective to determine who was publishing the post (patient, friend, or family of patient, business, or organization); tone (positive or negative); and content (education, advertisements, research, media coverage, or patient experience). Other methods may be used to quantify content and summarize outcomes. Secondary outcomes from social media included analysis of hospitals, subspecialty surgeons, and businesses as a surrogate of an analysis of the marketplace in health care. After data collection and scoring based on a set of parameters was completed, analysis was performed to assess the overall tone and content of patients’ posts and absence or presence of reference to their surgeon or hospital.

Orthopaedic Patients on Social Media

Preliminary reports by the authors have indicated that the overwhelming majority of patients of orthopaedic surgeries tend to use social media to share personal photos following their operations with an overall positive tone. In the authors’ preliminary report on total joint arthroplasty (TJA), including total knee arthroplasty (TKA) and total hip arthroplasty (THA), it was found that out of 1,287 posts that used social media to report on their primary joint replacement, 93.2% shared a message with a positive tone versus the 6.8% that posted with a negative attitude [15]. This trend may be due to the intentional effort of social media users to share only positive content, the actual positive effects of the joint replacement, or a combination of the two.

Patients across the subspecialties of orthopaedic surgery are relatively consistent in the type of posts they choose to share concerning their surgical experience. Nearly all of those who had undergone ACL surgery shared personal photos that were posted one week postoperatively, and the majority of these posts were associated with a positive tone [12].

Similar positive results were found with total knee arthroplasty patients, total hip arthroplasty patients, shoulder arthroplasty patients, rotator cuff patients, and ulnar collateral ligament reconstruction patients [14, 15].

The content of the images, however, varied slightly more but predominantly depicted rehabilitation, return to play (RTP), and surgical sites. ACL patients most commonly posted about rehabilitation followed closely by RTP and surgical site [12]. TJA patients posted equally about their rehabilitative journey as well as their return to activities of daily living (ADLs) [15]. Shoulder surgery patients (shoulder arthroplasty patients and rotator cuff repair patients) posted more so regarding their surgical site while patients of ulnar collateral ligament reconstruction (or “Tommy John” elbow surgery) posted more about their return to play. Understandably, these findings may be related to the nature of the patient population for the given surgery and their target social media audience [14].

Although most patients tend to focus on social media posts concerning their personal experience, a modest portion (23%) did also make references to their performing surgeons as well as the hospitals they were admitted to [14]. These references were commonly positive, reflecting the patient desire to include their physician as a contributor to their positive experience and to share that with their social circles. Outside of Instagram and Twitter social media use, patients often also take advantage of physician-rating websites to share their orthopaedic experiences. Five of the busiest physician-rating sites were analyzed for patient-published ratings and reviews for every orthopaedic surgeon listed. The overall orthopaedic surgeon rating was positive, ranking at 4.1/5 with no notable difference between academic and non-academic affiliated surgeons [9].

Other includes Education, Imaging, Industry Ads.

*Adjusted for six-month time frame to 2 year time frame.

Figure 1. Summary of analysis of patient social media content across six different orthopaedic procedures.

The use of social media data analytics may provide insights on how doctors and hospital organizations are using social media to enhance their practices by creating and maintaining an active social media presence. Indeed, an active social media presence may result in increased visibility that leads to increased elective surgical volume. One study by the authors evaluated the relative social media presence of surgeons specializing in shoulder and elbow surgeries. Less than half of surgeons who specialized in shoulder and elbow surgeries maintained active

Twitter accounts with an average of nearly 50 posts total. Among these surgeons maintaining a Twitter presence, the majority referenced their practice website and ways to schedule an appointment on their accounts. The study also found that all Top 5 US News and World Report orthopaedic surgery hospitals analyzed kept active Twitter accounts and participated much more, with an average of ~300 total posts. The content of the posts over a 2-year period focused more on education and community engagement rather than purely orthopaedic surgeries, with an even smaller amount related to shoulder and elbow surgeries [14]. Comparatively, more physicians specializing in ACL surgeries participated on social media via Twitter, although none were found to use Instagram. The hospitals analyzed in the context of ACL surgeries were found to use mostly Twitter and some used Instagram, where most of the posts on both platforms were centered on patients or celebrities [12].

Hospitals with a social media presence are working to capture the market and draw a greater patient population. This approach requires an investment of resources to adopt a connection between the hospital and online health consumers. The studies found that 19% of posts that hospitals shared on social media engaged with local community efforts and promoted prominent celebrities [14]. Additionally, hospitals often shared patient stories and experiences as a means to emphasize the importance of patient-centered health care. Similarly, there was an increased tendency to involve mid-level providers, such as physician assistants and nurse practitioners, in the hospital social media presence. This effort directly reflects the strategic response of hospitals to the growing number of non-physician providers who dedicate more bedside time to patients than physicians themselves and thus may act as a greater influence on the patient experience. Because potential patients now have the ability to easily compare several providers and hospitals with more information through better accessibility via the internet, hospitals that strategically invest resources into a social media presence may maintain an advantage with a higher likelihood to thrive in the healthcare market competition [12].

Limitations

Despite the conclusive findings through these social media analyses, it is important to note several limitations regarding patient posts based on population strata and personal biases, among others.

Social media use requires a population with access to smart phones and Internet as well as with sufficient technological literacy to navigate through the social media sphere. This may limit the population size of orthopaedic patients to a skewed population pool, which depending on the social media platform, may favor a higher proportion of younger patients. Additionally, social media users include both actively engaged participants and silent users who follow social media without contribution. Also, our studies were only able to capture public, not private, posts with hashtags, which understates the actual number of relevant posts [4].

Social media users maintain the potential to misrepresent and manipulate events in deliberate attempt to stage a public perception. To this end, one common criticism of frequent social media users is their predilection to glorify or self-promote themselves and their achievements, resulting in a false impression of reality that may either overstate the positive tone or exaggerate relatively minor negative events [12]. This may mean that individuals are

generally inclined to share material via social media when they feel an extreme sense of positivity or negativity associated with their experience. In an online community of social media users, there may be a trend to impress one another with their actions. Thus, this tendency to share extremely positive or negative experiences may skew the sample of posts analyzed in these studies.

It is important to note that a user may post multiple times with the same hashtag, resulting in a skew in the patient representation that may need to be adjusted in data content analysis. On this note, social media posts are often shared with a specific intention or directed purpose, which influences the content and tone of content on an ongoing basis. These limitations indicate a significant portion of orthopaedic patients whose presence on social media is greatly overshadowed by more active users.

Companies that utilize social media may also manipulate the messages they post to promote their products or services to their target patient audience. Stem cell therapy businesses that were studied were found to utilize a network of physicians that tend to advertise predominantly positive outcomes and broadly invite patients to seek treatments. Online strategies, such as the application of several hashtags, were employed by businesses to enhance visibility. However, the patient-published posts showed mixed results in visibility. This report highlighted that businesses were possibly leveraging social media with direct-to-consumer advertising that may mislead patients by illustrating only positive results without providing clear information regarding the risks, benefits, and limitations of the therapies. The authors proposed the need for increased regulation with sanctions to prevent businesses and physicians from advertising for therapies that as yet remain unproven [11].

Furthermore, the global coverage of social media may be diffuse and scattered. The analysis conducted on stem cell therapy content in social media showed that there was a preponderance of social media content centered from the United States, with secondary content located in the Indonesia, U.K., Canada. This means that penetrance of market and associated social media content may vary considerably according to the platform used and the target consumer group [11].

Another issue that arises when analyzing social media is the extent to which context plays a role on the meaning and interpretation of users' posts. Not only does this include the personal and social environment that influences an individual's post, but also the chronological context. With the progression of time comes advances in technology and proportional changes in the nature of social media. Although these changes occur gradually day-by-day, analyzing trends from a larger time scope too easily generalizes the transition and ignores important pivots in social media content. For example, realizing the change between posts of texts, pictures, and videos is second of importance to noting when and why social media users promoted the transition. However, evaluating these time-based changes requires constant and active analysis of individual social media and making connections, and this poses a difficulty in social media analysis.

OVERCOMING LIMITATIONS

To overcome these limitations, it is imperative to interpret data from these social media platforms qualitatively, not quantitatively. To do so, social media should be "listened" to, rather than used to support or reject a preconceived hypothesis. Large numbers of patients presenting a certain perception about orthopaedic care may offer important insight; however, even the few that seem to swim against the current can offer valuable constructive information that may result in long-term higher quality patient care. Acknowledging the presence of individuals who challenge the general consensus as well as understanding the context from which their sentiment stems provides indispensable insight into all recipients of orthopaedic care, not just the majority opinion. This integration of a qualitative approach to quantitative data will allow for directed improvements by addressing overlooked concerns and for better management of orthopaedic patient satisfaction [4].

A STEP INTO THE FUTURE

This research has the potential to affect the way physicians interact with their patients. Physicians and health care providers have the accreditation to speak on the topic of health care consumption. Physicians may feel that because of HIPAA concerns or hospital policy it is not permissible to share experiences and insight on social media platforms. Yet, physicians and healthcare providers should consider "owning" their own social media presence, using it as a tool to provide support to patients and their practices while still maintaining patient confidentiality.

This analysis of social media utilization in orthopaedic surgery serves as an excellent case study for the possibilities of future insight into other specialties and platforms. While social media may not be easily incorporated into every practice or hospital setting, there are certain referral-based medical and surgical subspecialties that may directly benefit from the insight that social media has to offer into their marketing portfolio.

In the future, social media data analysts expect the role of data science to become increasingly useful. A recent report published by the Harvard Business Review outlines that data scientists are becoming more proficient at leveraging social media data to make

decisions to improve advertising that result in increased consumer interest and revenue streams [8]. A similar strategy could be employed by academic and private hospital institutions and small private practices to improve patient interest in increasing referrals and gaining market access in new, innovative procedures.

Social media data analysts expect that social media platforms will continue to play a role in increased dialogue in the online marketplace, serving as a source of educational and informational utility to prospective patients and would-be-consumers. Furthermore, other social media platforms may play a role in “word of mouth” type referrals to follower and friend audiences, as they already do to some degree. Social data engineers have cited the role of friends in decision-making points, with determining what household appliances to purchase to which hospitals provide the best point-of-care for certain rare diseases. Finally, we expect to continue to see a growing role in terms of how feedback is based back to physicians, along with continued depiction of real time results from patients to prospective patients. Other specialties outside of orthopaedics have seen a growth in social media usage; in particular, dermatology and plastic surgery have seen growth in content across platforms [6].

CONCLUSION

Social media content has proven to be a unique and powerful tool for investigating the patient perspective, whether in orthopaedic surgery or other specialties. This data provides insights into the factors that are most important to patients, including ADLs and rehabilitation, which can guide patient counseling and improve expectation management with the enhanced understanding of outcomes. Furthermore, this increasingly popular modality serves as a revealing instrument for surveying the marketplace landscape, including hospital and surgeon perspective, to the end of characterizing and quantifying “word of mouth” effects in medicine as the health care economy becomes increasingly consolidated and competitive. Ultimately, the insights gained through our social media analysis of orthopaedic surgery may be applied to better understand and improve patient-perceived outcomes in all subspecialties of medicine and surgery.

Chapter 432

QUALITY OF LIFE CHANGES RELEVANT TO EXTENT OF THYROID SURGERY

Fatima Z. Syed*, MD

Division of Endocrinology, Jefferson Medical College and Hospital,
Philadelphia, PA, US

ABSTRACT

One of the most frustrating facets of clinical thyroidology is to deal with the unhappy patients who have iatrogenic post-surgical hypothyroidism. These patients frequently have complaints of brain fog, weight gain and fatigue without any easy “fix.”

These symptoms predominate frequently in the post-operative patient and are obviously real because they occur so frequently! “Prevention is better than cure” so we need to, where appropriate, minimize the extent of thyroid surgery as it would appear that some endogenous remaining thyroid hormone minimizes these symptoms as opposed to no endogenous thyroid function where these symptoms predominate. Future efforts need to be directed to more adequately defining appropriate thyroid hormone replacement and which compounds fare best? Finally perhaps the future rests on stem cell or related technique to retain endogenous thyroid hormone function?

Dr Syed addresses these issues in her narrative and provides some guide in minimizing extent of thyroid surgery where appropriate as well as attempts to appropriately replace physiological thyroid hormones and which compounds to use?

CASE REPORT ONE

Mrs. DS is a 65 year-old Caucasian female with history of well-controlled hypertension. Four years ago, she presented with a left sided two-centimeter thyroid nodule. Biopsy was consistent with papillary thyroid cancer, classical variant. She underwent a total thyroidectomy. Pathology was consistent with papillary cancer classic type 2cm in size. She did not have vascular invasion nor did she have any lymph node involvement. She did not

* Corresponding Author's Email: Fatima.syed@jefferson.edu.

receive radioactive iodine. Today, she presents to you for follow-up. At each visit in the last four years, she complains of fatigue, which did not exist prior to her surgery. Utilizing the Brief Fatigue Inventory, she states that she is fatigued at a score of 7/10 currently. At her worst, her fatigue is 10/10. Most of the time, she lives near a fatigue score of 8/10. She states that the fatigue affects her mood, her ability to exercise, and has interfered with work. She had planned on working into her 70s but states she feels so tired, she retired from her work as an accountant last year. She attributes the fatigue beginning after her thyroidectomy. She has been on a steady dose of levothyroxine 112 mcg for many years and has been biochemically euthyroid at your last five visits together. She ends the appointment by stating, "I wish I had never gotten my thyroid removed."

CASE REPORT TWO

Ms. Y is a 33 year-old East Asian female with history of papillary thyroid cancer status post total thyroidectomy here for follow-up. Three years ago, during a routine GYN visit, she was noted to have a right-sided thyroid nodule. She had no history of radiation in the past and she had no family history of thyroid cancer or other malignancies. She underwent a biopsy of the nodule, which came back as papillary thyroid cancer. She underwent total thyroidectomy and had a 3 cm nodule with classical PTC showing lymphovascular invasion. She received radioactive iodine as well. She comes today for follow-up. She is on levothyroxine at 100 mcg daily. She has been biochemically euthyroid for over one year. She complained of having low energy. She feels she is not functioning as well as she should and sleeps poorly at night. She screens negative for depression and has no other medical issues or stressors. She does have an eight month old daughter. However, her daughter is sleeping through the night and she does not believe motherhood is the source of her fatigue. She states that since her thyroidectomy and starting thyroid replacement, she has never felt the same.

CASE REPORT THREE

Mr. W is a 46 year-old who was diagnosed with papillary thyroid cancer, classic variant seven years ago upon discovering a palpable nodule on the right side of his thyroid whilst shaving one morning. He underwent biopsy, which showed the results as stated. He has no exposure to radiation. His mother also had papillary thyroid cancer and underwent total thyroidectomy. He was referred for surgery. It was ultimately decided that patient would undergo a right lobectomy as the nodule was only 2cm in size. Pathologically the right lobe showed 18mm papillary thyroid cancer without lymphovascular invasion. Post-operatively his thyroid function remained within normal range without the need for thyroid hormone replacement. He did however have minimal weight gain and complaint of fatigue in follow up.

INTRODUCTION

“I haven’t been the same since my thyroid was removed.” This is a common complaint endocrinologists hear from patients who have undergone total thyroidectomy. Before examining symptoms associated with thyroidectomy, it is first important to understand the role of the thyroid and the effects and treatment of hypothyroidism. The most common cause of hypothyroidism globally is iodine deficiency [1] Vanderpump, 2011. However, in the United States and other developed nations, the most common cause of hypothyroidism is autoimmune thyroid disease [2] Haugen et al., 2015. Amongst leadership in clinical guidelines, screening for hypothyroidism is not generally recommended. However, in cases of other autoimmune disease, family history, history of radiation, or personal history of thyroid surgery, screening of thyroid function is recommended. Of course, if a patient has symptoms of hypothyroidism, he or she should be screened [2, 3] Haugen et al., 2015, Garber et al., 2012.

Patients who have their thyroid gland surgically or radioactively removed require lifelong thyroid replacement [2] Haugen et al., 2015. Typically, thyroid replacement involves replacing levothyroxine at 1.6 micrograms/kilogram for all patients [4] Devdhar et al., 2011, regardless of the etiology of hypothyroidism. However, according to the American Thyroid Association, patients who have had surgical thyroidectomies may require more replacement [2] Haugen et al., 2015. This can be adjusted based on symptoms of the patient. Thyroid replacement is therefore based on both qualitative and quantitative measures.

Traditionally, patients that are status post thyroidectomies TSH are initially suppressed and then are maintained to be biochemically euthyroid [5] Massolt et al., 2016. However, in our case reports above, we find a common complaint amongst these patients is that they may not feel as they did before thyroidectomy, despite effective treatment of thyroid hormone replacement. The aim of this chapter is as follows:

1. Examine quality of life for patients who have undergone thyroidectomies
2. Understand the objective measurement tools of quality of life
3. Review treatment options of PTC and examine morbidity and mortality associated with PTC
4. Understand the perceptions of lobectomy versus thyroidectomy

OBJECTIVE MEASUREMENTS OF QUALITY OF LIFE

In evaluating patients with history of thyroidectomies, it is important to ask the symptoms the patient experiences as well as if those symptoms are tolerable or not. This can help guide supportive care for the patient. Several objective measures on quality of life can be applied to patients who have had total thyroidectomies.

Massolt et al. describe the following quality of life measures [5].

Thyroid Specific Patient Reported Outcome Measures (ThyPRO)

This is a qualitative survey containing eighty-five questions summarized in 13 scales. It accounts for cross-cultural [6, 7] Bukvić et al., 2015, Watt et al., 2015 and socio-economic validity [5] Massolt et al., 2016..

Multidimensional Fatigue Index (MFI-20)

This is a twenty-question survey which evaluates generalized fatigue, physical fatigue, mental fatigue, reduced motivation and reduced activity [5, 8] Massolt et al., 2016, Smets et al., 1996.

RAND-36

This is a validated Dutch survey on evaluating overall health in the prior thirty days [9] VanderZee et al., 1996. It consists of nine subclasses, including physical health problems, limitations of emotional and general health care needs.

Cancer Quality of Life Survey

This is a survey typically for patients before and after chemotherapy, however it is also helpful in evaluating depression and fatigue in patients with history of cancer [5] Massolt et al., 2016.

THYROIDECTOMY PATIENTS PERCEPTIONS OF QUALITY OF LIFE VS AGE NORMATIVE POPULATIONS

In a study by Husson et al, quality of life of patients with thyroidectomy is compared to age normative populations [10]. Consistently, it is found that patients with thyroidectomy have decreased quality of life compared to age normative populations. Patients with thyroid cancer have comparable life expectancies as patients without thyroid cancer [11], Links et al., 2005. Given the length of life expected by these patients, according to the study, any impacts to quality of life become concerning. The study aims to “assess [thyroid cancer specific] Health Related Quality of Life (HRQoL) among long-term thyroid cancer survivors and to compare this with the HRQoL of an age- and sex-matched normative population. Secondly, our aim was to investigate which clinical and socio-demographic characteristics and thyroid cancer specific problems were associated with HRQoL”¹⁰ Husson et al., 2013.

The study surveyed patients over a twenty-year period of new patients diagnosed with thyroid cancer. It used objective surveys to assess disease specific symptoms. These scores were then compared with age and sex matched disease free controls. Confounding factors such as socio-economic status were addressed¹⁰ Husson et al., 2013.

The study found that “Thyroid cancer survivors had significantly lower scores on physical, role, emotional, cognitive and social functioning ($p < 0.001$) compared to the normative population after adjusting for comorbidities. Sympathetic problems [feeling chilly (52%), hot flushes (40%)], neuromuscular problems [cramp legs (43%) and pain joints/muscles (64%)] and abrupt attacks of fatigue (50%) were the most often reported thyroid cancer specific complaints. Thyroid cancer specific neuromuscular, concentration, sympathetic and psychological problems explained 41–58% of the variance in HRQoL. Clinical and socio-demographic factors explained a small part of the variance in (thyroid cancer specific) HRQoL (1–27%)”¹⁰ Husson et al., 2013.

Further studies have shown that patients with thyroid cancer who have undergone thyroidectomy are at higher risk of unemployment¹² Ratzon et al., 2016. Patients report fatigue as reasons for unemployment. It is difficult to correlate fatigue alone as reason for unemployment, which is a complicated issue. However, the correlation with thyroid cancer survivorship does indeed exist¹² Ratzon et al., 2016.

Overall, patients who have thyroid cancer and survived will likely have worse quality of life had they never had thyroid cancer and required a thyroidectomy [13] Lee et al., 2010. There is not objective data as to why patients with thyroidectomy have worsened quality of life. Obvious thought is that the thyroid produces some endogenous substance [5] Massolt et al., 2016, which contributes to energy that is beyond thyroid hormone alone. Additionally, many with PTC have some component of autoimmune thyroid disease [2] Haugen et al., 2015. Autoimmunity itself may not disappear after surgery, and it is possible, this is causing the residual fatigue and impairment to perceived quality of life [5, 14] Massolt et al., 2016, Hirsch et al., 2009.

THYROIDECTOMY VERSUS LOBECTOMY IN TREATMENT OF THYROID CANCER AND EFFECTS ON QUALITY OF LIFE

According to a study done at Memorial Sloan Kettering over a twenty- year period, there was no difference in mortality in patients who received a total versus partial lobectomy for non-invasive thyroid cancer [15] Nixon et al., 2012. This study only included patients with thyroid cancers that were less than or equal to 4 cm in size and with no known invasion of lymph nodes or spread outside the neck. “A total of 361 patients were treated with lobectomy and 528 were treated with total thyroidectomy. As expected, the survival at 10 years was high in both groups of patients (93% in the lobectomy and 91% in the total thyroidectomy group). There were no significant differences in 10 year survival or thyroid cancer recurrence between the two groups of patients. Both age greater than 45 and male gender were predictive of a worse overall survival, while the type of surgery had no effect on survival” [15] Nixon et al., 2012.

According to Husson et al. and other studies, patients with lobectomy still report worse quality of life in comparison to those without thyroid cancer [10].

CONCLUSION

In all three cases, the commonality was that patients felt worse after thyroidectomy than before. There are many reasons this could be the case. In those with cancer survivorship in general, quality of life is perceived worse after cancer than before even decades after cure [16] Schlumberger M, 1999. Therefore, thyroid cancer, although mostly has high levels of long term survivorship, is not different than other cancers. Perhaps evaluating patients' quality of life before and after would be helpful in evaluating their perceptions of symptoms. Also in low risk thyroid cancer perhaps minimalistic surgery (lobectomy), leaving patients with some functioning thyroid tissue of their own, may alleviate some of the fatigue and weight gain attendant with total thyroidectomies without compromising longevity nor recurrence risk?

ROBOTIC SURGERY FOR PROSTATE CANCER: FUNCTIONAL AND ONCOLOGICAL OUTCOMES IN A LAST GENERATION REFERRAL CENTER

***Elio Mazzone, Riccardo Bientinesi, Carlo Gandi,
and Pier Francesco Bassi and Emilio Sacco***

Urologic Department, Agostino Gemelli University Hospital Foundation,
Catholic University Medical School of Rome, Italy

ABSTRACT

Objective. Robot-assisted laparoscopic radical prostatectomy (RARP) has been introduced from more than fifteen years and has rapidly become the main surgical option for localized prostate cancer. Our aim was to report complications, intraoperative outcomes, postoperative oncological and functional outcomes in a recent series of RARP performed in a robotic surgery referral centre of last generation.

Patients and Methods. Between January 2013 and January 2015, 164 consecutive patients (mean age 65.2 ± 6.8) underwent RARP at our centre. 52 RARP were performed with a nerve-sparing (NS) technique. Oncological outcomes were reported as positive surgical margins (PSM) and 1-yr biochemical disease-free survival (1y-bDFS). Biochemical recurrence was defined as a repeated prostate-specific antigen >0.2 ng/ml. Urinary continence was evaluated using the University of California-Los Angeles Prostate Cancer Index-Urinary Function (UF) score (1-100) and pad use. Sexual function was evaluated using the UCLA PCI-Sexual Function (SF) score (1-100) and the Erection Sufficient for Intercourse (ESI) criteria. To evaluate the learning curves, we equally divided patients into eight groups (case orders) based on the time of surgery and compared mean blood loss, mean operation time, functional results and PSM among patients groups.

Results. The mean intraoperative blood loss and the mean operative time were respectively 284.4 ± 110.4 ml and 146.5 ± 40.1 minutes. There were 1.2% major (Clavien III-IV) and 7.9% minor (Clavien I-II) postoperative complications, with no mortality. The overall prevalence of PSM was 30.5% (50/164). The PSM rate for pT2 and pT3 disease was 23.6% and 57.6%, respectively. At multivariate logistic regression analysis,

postoperative Gleason grade was the only independent predictor of PSM (OR 3.81; 95%CI 1.65-8.84; $p = 0.002$).

A nerve-sparing procedure did not affect the risk of PSM. In patients with at least 1-yr follow up, 1y-bDFS was 90.8%. At a median follow-up of 18 months, 71 patients (72%) were fully continents. The mean UCLA PCI-UF score was 71.3 ± 27.9 (0–100). On multivariable logistic regression, age (OR 0.881; 95%CI 0.79-0.98; $p = 0.02$) and pathologic Gleason Score (OR 0.118; 95%CI 0.05-0.69; $p = 0.012$) were independent predictors of continence recovery. Considering only patients who undergo NS technique, potency rate was 50% according to ESI criteria, and mean UCLA PCI-SF score was 46.5 ± 32.6 (1–100). The learning curve effect was observed for mean blood loss and mean operation time, which significantly decreased throughout case orders ($p < 0.001$). No significant learning curve effects were observed in oncological and functional outcomes.

Conclusion. RARP appears to be a safe procedure in last generation centres, with a very low complication rate and blood loss. Oncological and functional outcomes are overall in compliance with that reported in the recent literature. The learning curves analysis showed that intraoperative outcomes improve after a relatively small number of cases, while oncological and functional outcomes remain unchanged overtime and may need more time for further improvement. Long-term, prospective, and possibly randomized studies are needed.

1. INTRODUCTION

The history of robotic surgery started 20 years ago. Robotic surgery aims to improve the advantages and the results of the mini-invasive video-assisted surgery while simplifying the surgeon's job. Actually, the term tele-surgery is more specific because the surgeon manages instruments similar to those used in laparoscopy while remaining located at a specific console rather than at the operation table. The most recent and advanced *da Vinci*[®] surgical system (Intuitive Surgical, Inc.) is composed from three main parts. The first part is the console, set up on a distance from the operation table. The first operator controls the console while the assistant provides the instrumental equipment to the robotic hand and the inserting it to the patient's body. The second part is the surgical trolley equipped with four hands that are all capable of setting up a wide range of surgical instruments. The third part is the visualization system that provides a magnified three-dimensional image of an operation area. The use of the robot involves significant advantages in front of the video-assisted mini-invasive surgery. The *da Vinci*[®] robot increases the dexterity of the operator and allows more accurate eye-hand coordination, favours more ergonomic position of the console and improves vision with a three-dimensional image. In addition, the robot eliminates the trembling of the hands and improves the movement of the surgical instruments thanks to the *Endo-Wrist*[®] technological system. Comprehensively, the learning phase becomes faster, especially for surgeons experienced with video-assisted mini-invasive laparoscopic surgery. However, there are some disadvantages such as the loss of a tactile sensation and tension sensibility, which could provoke unperceived lacerations of organs or tissues. Furthermore, the positioning of the instrumentation atop the patient (the pre-operative preparatory procedures) requires some additional time and particular knowledge of the operational stuff, extending operative and narcosis time.

The first procedure of robot-assisted radical prostatectomy (RARP) was performed in Frankfurt, in May 2000, by a team of surgeons without any specific preparation in laparoscopy. The team followed partially the anterograde and partially the retrograde approach, similar to the retro-pubic radical prostatectomy (RP) technique originally described by Walsh and Campbell. Simultaneously, other European surgeons, with more experience in the laparoscopic field, reproduced with the new robot the Montsouris' anterograde and Heilbronn's retrograde technique. In the US, Menon, Guillenau and Vallancien performed the first 22 cases at the Vattikuti Institute of Urology (Detroit) applying the Montsouris' technique originally described by Gaston. For the following 18 cases, Menon et al. developed an original surgical technique that became the most common technique for the RARP, the Vattikuti Institute Prostatectomy (VIP) [1]. More than thousand operations were performed using the new anterograde and transperitoneal technique. Just a few years after, Ahlering et al. made important modifications of the technique, introducing innovative method of dissection of the prostatic apex and control of the Santorini's venous complex with vascular clips. In the following years the attention focused on the development of a technique that could preserve the nerve fibers involved in sexual function and continence, the so-called "nerve-sparing" (NS) technique. In 2005, Kaul et al. [2] performed the first VIP NS operation that included the preservation of the prostatic nerve bundle. The same year, Ahlering group described a cauterisation-free NS technique using only the laparoscopic bulldog clips and FloSeal for the haemostasis. Another interesting NS technique, performed without use of clips and monopolar electrocautery, was described by Chien et al. [3]

Our aim was to evaluate intraoperative outcomes, postoperative oncological and functional outcomes and complications in a recent series of RARP in order to display the results in a robotic surgery referral centre of last generation. Furthermore, we analysed the learning curves for RARP of a surgeon without previous laparoscopic experience.

2. MATERIALS AND METHODS

2.1. Study Characteristics

We performed a retrospective study using prospectively collected data at Urological Clinic of "Agostino Gemelli" University Hospital Foundation of Rome. Between January 2013 and January 2015 all consecutive patients undergoing RARP for clinical localized prostate cancer (cT1-cT3N0M0) were included.

2.2. Surgical Technique

The procedures were performed by a single surgeon (P.F.B.) using a standard six-ports transperitoneal technique and the *da Vinci*® SI robotic system (Intuitive Surgical, Inc). The patient was placed in a dorsal lithotomy position with the lower limbs in slight abduction. Using the Hasson technique, a 12 mm port was introduced in abdominal cavity just above the umbilicus to induce pneumoperitoneum. Afterwards, under video assistance three 8 mm robotic trocars and an assistant 12-mm robotic trocar were introduced through a traversal line

passing 14 cm above the pubis, and one more assistant 5 mm port was placed in right hypochondr. The next steps were performed in chronologic order: (1) incision of the peritoneum of Douglas space freeing up the seminal vesicles and the deferens vas that were divided; (2) dissection of the Denovilliers fascia and separation of the posterior aspect of the prostate from the rectum until the prostate apex; (3) incision of the anterior peritoneum bilaterally to the umbilical vessels with access to the Retzius space; (4) prostatic defatting and incision of the endopelvic fascia with exposure of the prostate apex; (5) dissection of pubo-prostatic ligaments and preventive control of the dorsal vein complex of Santorini; (6) bladder-prostate dissection up to the level of the seminal vesicles previously freed-up using a bladder neck-sparing procedure; (7) control of the postero-lateral neurovascular bundles with Hemo-lock and completion of the anterograde prostate posterolateral dissection, with NS technique when indicated; (8) dissection of the prostate apex, urethral section and total prostate-vesiculectomy; (9) vesico-urethral anastomosis with barbed suture and Van Velthoven technique. The specimen was extracted through a small supraumbilical midline incision.

2.3. Outcomes and Variables

We considered mean blood loss and surgical time as intra-operative outcomes. Post-operative complications were classified using Clavien-Dindo score. In terms of cancer control, we considered positive surgical margins (PSM) and 1-year biochemical disease-free survival (1y-bDFS) as oncological outcomes. A PSM was defined as the extension of tumour to the inked surface of the specimen. All surgical specimens were evaluated by a single pathologist at the same institution. Recurrence was defined as a repeated prostate-specific antigen ≥ 0.2 ng/ml.

Urinary continence was evaluated by the Urinary Function score (questions from 2 to 6) of the University of California Los Angeles Prostate Cancer Index (UCLA-PCI-UF) [4]. Continence was defined as no pad use (answer 3 to question 4). Potency was evaluated by the Sexual Function score (questions from 7 to 10) of the UCLA-PCI questionnaire (UCLA-PCI-SF) [4]. Potency was defined using the Erection Sufficient for Intercourse (ESI) criteria. Each questions' score was converted into a scale from 0 to 100, higher score corresponding to better function.

For the evaluation of postoperative oncological and functional outcomes only patients with a minimum one-year follow-up were considered. Furthermore, only preoperatively potent patients who underwent RARP with NS technique and who did not receive postoperative radiotherapy or hormonal therapy were considered for potency evaluation.

To define a learning curve, we equally divided patients into eight groups (case orders) based on the time at surgery. Variables considered in the learning curves are the mean duration of the operation, mean blood loss, PSM and functional outcomes.

2.4. Statistical Analysis

Statistical analyses were performed with MedCalc statistic software. Continuous variables were reported as mean valued plus standard deviation (SD). Students' t test and

Pearson' chi-square test were utilized to compare continuous variables and categorical variables, respectively. To evaluate the variables as hypothetic predictive parameters of the considered outcomes, univariate and multivariate logistic regression analysis were performed. A p value < 0.05 was considered as statistical significance index.

3. RESULTS

Overall, 164 patients were included. The patients' mean age ($\pm$ SD) was 65.2 ($\pm$ 6.8) years. Table 1 shows the most relevant patients baseline characteristics.

Table 1. Patients baseline characteristics (n = 164)

Mean age, years $\pm$ SD	65.2 $\pm$ 6.8
Mean prostate volume, ml $\pm$ SD	45.2 $\pm$ 18.0
Bioptic Gleason score, n (%)	
5	1 (0.6)
6	91 (55.5)
7	59 (36)
8	10 (6.1)
9	3 (1.8)
Clinical stage, n (%)	
T1	123 (75)
T2a	31 (18.9)
T2b	7 (4.3)
T2c	3 (1.8)
Charlson index, n (%)	
≤ 3	31 (18.9)
4	50 (30.5)
5	52 (31.7)
≥ 6	31 (18.9)
IIEF-5 score mean (1-25)	16.6 $\pm$ 7.4
PSA mean, ng/ml $\pm$ SD	8.8 $\pm$ 5.3
Mean PSA density, ng/ml/cc $\pm$ SD	0.15 $\pm$ 0.07
Risk class by D'Amico, n (%)	
Low risk	71 (43.3)
Intermediate risk	77 (46.9)
High risk	16 (9.8)

3.1. Operative Outcomes

The mean intraoperative blood loss and the mean operative time were 284.4 $\pm$ 110.4 ml and 146.5 $\pm$ 40.1 minutes, respectively.

In terms of postoperative complications, there were 1.2% major (Clavien III-IV) and 7.9% minor (Clavien I-II) events, with no mortality. We observed one rectal perforation (the only one intra-operative complication), which was repaired intra-operatively; 2 laparotomic explorations for postoperative haemorrhage; 4 bladder neck contractures; 2 external corps (Hemo-lock) in urethra that have been removed cystoscopically; 7 urinary fistulas with pelvic urinoma managed conservatively.

3.2. Oncological Outcomes

Table 2 displays the main pathological outcomes. The overall prevalence of PSM was 30.5% (50/164). Organ-confined prostate cancer (pT2) was found in 131 patients (80.1%), while remaining 33 patients (19.9%) had an extra-prostatic extension (pT3). The PSM rate for pT2 and pT3 disease was 23.6% and 57.6%, respectively. Apex was the most common PSM site (42%), followed by posterolateral site (30%).

Table 2. Pathological outcomes (n = 164)

Pathological Stage T, n (%)	
pT2a	17 (10.2)
pT2b	2 (1.2)
pT2c	112 (68.3)
pT3a	25 (15.2)
pT3b	8 (4.8)
Pathological stage N, n (%)	
N0	76 (46.3)
Nx	84 (51.2)
N1	4 (2.4)
Gleason score, n (%)	
6	66 (40.2)
7 (3+4)	72 (43.9)
7 (4+3)	18 (11.0)
8	8 (4.8)
PSM, n (%)	50 (30.5)
PSM location, n (%)	n = 50
Apex	21 (42)
Posterolateral	15 (30)
Others	14 (28)
Mean length PSM, mm $\pm$ SD	8.58 $\pm$ 7.81
EPE, n (%)	34 (27.7)

PSM: positive surgical margins.

EPE: extraprostatic extension.

Table 3. Patients with disease recurrence

N° pts	Age	PSA ¹	Type of Recurrence	pT	pN	PSM	Gleason score ²	Therapy

8	67	4,4	Biochemical	2c	x	no	3+4	WW

¹Preoperative Prostate specific antigen.

²Definitive Gleason score.

PSM: positive surgical margins; RT: radiotherapy; HT: hormonal therapy; WW: watchful waiting.

We evaluated the association between PSM and pathological, clinical and operative variables. D'Amico risk group ($p = 0.015$), bioptic Gleason Score ($p = 0.025$), pathological stage ($p = 0.007$) and pathological Gleason Score ($p < 0.001$) were significantly related with histopathological evidence of PSM. Patients who received a NS procedure did not show an increased risk of PSM ($p = 0.443$)

Accordingly, at univariate logistic regression analysis, D'Amico risk group (OR 2.27; 95% CI 1.33-3.89; $p = 0.002$), pathological stage (OR 2.13; 95% CI 1.33-3.42; $p < 0.001$) and pathological Gleason Score (OR 5.64; 95% CI 2.69-1.09; $p < 0.001$) were strongly associated with PSM finding, while a NS procedure did not affect the risk of PSM ($p = 0.089$). At multivariate logistic regression analysis, pathological Gleason score was the only independent predictor of PSM (OR 3.81; CI 1.65-8.84; $p = 0.002$).

Table 3 shows the clinical and pathological characteristics of patients with disease recurrence in the subgroup of 87 patients with at least 1 year of follow up. One year-bDFS was 90.8%. The median time of follow-up was 18 months. Disease recurrence was only biochemical in 6 patients (6.8%) and clinically detectable as localised relapse in 2 patients (2.3%).

3.3. Functional Outcomes

Evaluation of the urinary function included 92 patients (mean follow-up = 18 months). According to our definition of continence, at last follow-up 71 patients (72%) were completely continent (Figure 1). Mean UCLA PCI-UF (Urinary Function) score was 71.3 ± 27.9 . Patients that underwent monolateral nerve-sparing (MNS) technique (78.4 ± 28.0) and bilateral nerve sparing (BNS) technique (76.7 ± 25.3) showed higher scores than patients that underwent a non-NS technique (67.4 ± 28.2); however, the difference were not statistically significant ($p = 0.1226$) (Figure 2).

Figure 1. Percentages of patients using no pad, 1-2 pads or 3 or more pads daily at last follow-up.

Figure 2. Mean UCLA PCI UF scores in patients undergoing non nerve-sparing (NS) procedure, monolateral nerve-sparing (MNS) and bilateral nerve-sparing (BNS).

Figure 3. Percentages of potent patients considering ESI (Erection Sufficient for Intercourse) criteria for potency definition. The percentages for all patients undergoing a nerve-sparing procedure (NS tot), mono-lateral (MNS) and bilateral NS procedure (BNS) are shown.

Figure 4. Mean UCLA PCI SF scores in all patients undergoing nerve-sparing procedure (NS tot), mono-lateral (MNS) and bilateral NS procedure (BNS) are shown.

Variables included in the statistical analysis of continence recovery were age, age-adjusted Charlson comorbidity score, preoperative PSA, biopsy Gleason score, clinical stage, pathological Gleason score, pathological stage, radiotherapy, ormonotherapy and NS (yes/no). The results of the univariate logistic regression show that the older age (OR 0.906, 95% CI 0.84-0.97; $p = 0.005$), higher age-adjusted Charlson comorbidity score (OR 0.522, 95% CI 0.31- 0.86; $p = 0.027$), higher D'Amico risk class (OR 0.429, 95% CI 0.19-0.92; $p = 0.026$), higher preoperative PSA (OR 0.83, 95% CI 0.77-0.98; $p = 0.022$), higher pathological stage (OR 0.50, 95% CI 0.26-0.94; $p = 0.019$) and higher pathological Gleason score (OR 0.153, 95% CI 0.05-0.40; $p < 0.0001$) were associated to the continence outcome. At mutivariate analysis only age (OR 0.881, 95% CI 0.79-0.98; $p = 0.020$) and pathological Gleason score (OR 0.118, 95% CI 0.05-0.69; $p = 0.012$) were independent predictors for urinary continence.

Overall, 32 patients were included in the potency analysis. According to our definition of potency, 16 patients (50%) were potent. In the subgroup of 16 patients that underwent RARP with MNS technique, 8 (50%) resulted potent. An identical percentage of potency (50%) was observed in the subgroup 16 patients that underwent RARP with BNS technique (Figure 3). Overall, 50% of patients undergoing the NS procedure were potent at the last follow-up (average 18 months). The mean score of the UCLA PCI-SF for the patients undergoing NS technique was 46.2 ± 31.8 . The corresponding values for the patients undergoing MNS and BNS technique were 47.7 ± 31.8 and 45.4 ± 32.6 ($p = 0.8413$), respectively (Figure 4).

Variables included in the statistical analysis of potency recovery in patients undergoing the NS procedure were age, age-adjusted Charlson comorbidity score, preoperative PSA, preoperative IIEF-5 score, biopsy Gleason score, clinical stage, pathological Gleason score and pathological stage. The results of the univariate logistic regression showed that only the pathological Gleason score was a predictor of potency recovery (OR 0.264, 95% CI 0.06-1.03; $p = 0.037$). At multivariate statistical analysis no variables resulted to be independent predictor of potency recovery.

Figure 5. Mean operative time learning curve, dividing patients in eight groups.

Figure 6. Mean operative blood loss learning curve, dividing patients in eight groups.

3.4. Learning Curves

A learning curve was observed for both operative time and blood loss (Figure 5, Figure 6). The mean operative time decreased from 198 ± 43 minutes for the first group to 126 ± 18 minutes for the third group, and then plateaued at about 138 minutes. The mean blood loss increases to the highest value of 405 ± 122 mL in the second group of patients and then decreased and plateaued at about 230 mL. The differences in operative time and blood loss between the first patients group and the last patients group were statistically significant ($p < 0.0001$) for both variables.

Figure 7. Continence learning curve considering UCLA PCI UF score, dividing patients in eight groups.

The UCLA-PCI-UF score showed a rising trend but there was not statistically significant difference between the first (71.0 ± 24.5) and the last group (73.6 ± 27.7 ; $p = 0.168$) (Figure 7). Regarding the sexual function, due to the limited sample ($n = 24$), patients were assigned

to 6 groups of 4 patients each. Similarly to the urinary continence, a statistically significant learning curve was not found for the UCLA-PCI-SF score: mean scores for the first and the last group were 70.7 ± 25.8 and 46.5 ± 19.4 ($p = 0.198$), respectively (Figure 8). The PSM rate slightly decreased throughout the eight groups of patients, with no statistically significant differences among them ($P = 0.213$) (Figure 9).

Figure 8. Potency learning curve considering UCLA PCI SF score in patients who underwent nerve-sparing procedure, dividing patients in six groups.

Figure 9. Percentage of positive surgical margins (PSM) dividing patients in eight groups.

4. DISCUSSION

The analysis of the present surgical series of patients undergoing RARP in a referral centre of last robotic generation provided useful information about the evolution of the robotic surgery from its introduction more than fifteen years ago. In particular, we reported

complications, oncological and functional outcomes and evaluated the learning curve for several surgical parameters.

Major perioperative complications were very rare in our series. No conversion to open surgery was necessary indicating the high safety of RARP in modern series.

The presence of PSM in RP specimen is a known risk factor for disease recurrence and may generate patients anxiety. In the present series we observed a rate of PSM (30.5%), which is in the range of reported rates in the literature. In a collaborative review of PSM in RP, Yossepowitch et al. [5] selected 73 papers out of 768 and found PSM rates of 11–38%. These authors did not investigate differences among different surgical approaches.

Magheli et al. [6] reported on a group of 522 consecutive patients undergoing open RP, laparoscopic RP, and RARP at a single centre; while similar PSM rates were seen for open RP (14.4%) and laparoscopic RP (13.0%), a statistically significantly higher crude PSM rate of 19.5% was observed in the robotic RP group. In RARP series with sample size comparable to that of present study (Motttrie et al. 2007 [7], 183 cases; Atug et al. 2006 [8], 140 cases) the overall PSM rate varied between 16% and 26%, lower than our rate. The differences between different series may be explained by several factors such as differences in study population, surgical technique and protocol of anathomopatologic processing and reporting. It remains currently unclear whether RARP is superior, equivalent or inferior to open and laparoscopic RP with regard to oncological outcome [9]

The prognostic significance of PSM depends also on their location. The apex (42%) resulted to be the most frequent location in our series, followed by the postero-lateral site (30%). This pattern of PSM location is overall in adherence with that reported by some previous studies [10, 11, 12], although it remains a controversial point in the literature [13, 14]. In particular, Patel et al. reported that apex (36%) and postero-lateral sites (29%) were the most common PSM locations after RARP [15].

Our results did not indicate an association between the PSM and performing RARP with the NS technique. This is in disagreement with some previous findings [16] but in compliance with the results of other groups [17, 18]; as a result, this point remains controversial as well.

Few studies with small sample size have addressed clinical and pathological predictive factors for PSM after RARP. Pathological Gleason score was the only predictive risk factor for PSM at multivariate analysis in our series. This is in compliance with some previous studies reporting that parameters related to tumour aggressiveness were strong predictor of PSM status [19, 20, 21]. Others found pathological stage and preoperative prostate specific antigen being the most important independent predictive factors for PSM after RARP [22].

In our series total continence rate settled at 72% at last follow-up. This finding is in the range of values reported by major series in the literature [9, 10, 7]. In several studies comparing the functional results after laparoscopic and robot RP, the percentage of complete continence was similar. This percentage varied between 80% and 95% after a follow-up of 12 months [23, 7]. The wide variation in post-prostatectomy continence rate reported in literature is due to multiple factors such as definition of continence, time to evaluation, surgical technique and patient population. A comparison can be done with the studies of Witz et al. [24] and Shikanov et al. [25], which applying the same continence definition criteria as our study reported rates of 69% [24] and 68% [25], therefore in line with our results. In our logistic model, age and pathological Gleason score were the only negative predictive independent parameters for the continence outcome. This may be explained by the worsening of the pelvic muscle function with ageing and by the more aggressive resection performed by

the surgeon in patients with more aggressive disease (higher length of urethra resected, complete resection of neurovascular bundles, resection of bladder neck) [26]. Novara et al. [27] reported a significant association at multivariate analysis between continence outcome and age (OR 1.076, $p = 0.027$) and Charlson comorbidity score (OR 1.635, $p = 0.009$), partly in adherence with our results. The negative impact of the age on postoperative urinary function was also confirmed in other RARP series [28, 29]. Stanford et al. [28] reported that the men younger than 60 year were significantly more continent within two years than the older ones; Talcott et al. [29] reported a rate of continence of 95% within 12 months among men younger than 65 year compared to a corresponding value of 85% among older patients.

We observed a potency rate of 50% among patients undergoing a NS RARP. The recent meta-analysis conducted by Ficarra et al. [30] reported for the studies using our definition criteria for sexual potency (ESI) a rate of potency within 12 months ranging from 39% to 90% among patients undergoing NS procedure, confirming the huge heterogeneity among studies. Nevertheless, our study did not demonstrate any statistically significant differences between MNS and BNS procedure, in disagreement with previous studies [7]. The superior efficacy of the BNS technique compared to the MNS technique remains rather controversial in the existing literature. Mottrie et al. [7] was one of the first to report the different results according to the techniques (47% MSN vs. 70% BNS). The meta-analysis of Ficarra et al. [30] reaffirmed the potential advantage of the bilateral technique in front of the monolateral, although without demonstrating statistically significant difference at multivariate analysis (OR: 2.07; 95% CI, 0.98-4.41; p value not reported). In our study only the pre-operative IIEF-5 and pathological Gleason score were associated to potency, partially confirming the existing findings in the literature regarding the association between the pre-operative sexual function and the post-operative potency recovery [31]. Nevertheless, no independent predictive factors of postoperative potency were identified at multivariate analysis indicating that other factors should be analysed such as nuances in surgical technique.

Our analysis of the learning curves showed that in modern series there is still a learning effect, however it is limited to the very early group of patients at least in terms of operative time and blood loss, plateauing after only 20 cases for the operative time and after 60 cases for the blood loss. Menon et al. [1] reported similar results on operative time that decreased after just 18 patients. Galli et al. [32] observed similar decrease after 20 laparoscopic RP cases.

A statistically significant learning curve was not found for postoperative outcomes such as PSM, potency and continence. These results confirm what has been already observed in other series [33]: both operative time and blood loss demonstrated a tendency to decrease rapidly in the first phase of the learning curve, while in terms of functional and oncological outcomes, the results remained stable. However, there is heterogeneity in the results reported in literature on this point. Although the learning curve for PSM for RARP is not known, Vickers et al. [34] have demonstrated the presence of multiple learning curves for open RP. A series of 450 RARP cases showed that PSM rates varied from 36% in the first 50 patients to 17.6% in case numbers 51–250 to 7.5% in case numbers 251–450 [35]. Another study of 3794 patients who underwent RARP demonstrated that PSM rates improved with increasing surgeon experience; >1600 cases were required to get a PSM rate <10%, suggesting that our series may be too small for the identification of a learning curve effect [36].

This study do have some limitations restricting the generalizability of the results such as the retrospective design, the relatively small sample size, the single-centre nature and missing

data on other variables that are likely to have influenced our findings, such as body mass index and tumor volume.

CONCLUSION

RARP is a safety and effective procedure in a last generation high-volume referral centre. The overall rate and severity of intra-operative and post-operative complications were very favourable. In terms of oncological and functional outcomes, our results were overall in compliance with that reported in recent literature. The learning curves analysis showed that intraoperative outcomes improve after a relatively small number of cases, while oncological and functional outcomes remain unchanged overtime and may need more time for further improvement. Long-term, prospective, and possibly randomized studies are needed.

Chapter 434

INTRATHECAL BACLOFEN PUMPS IN SPINAL DEFORMITY AND ORTHOPEDIC SURGERY

Jonathan Weyhenmeyer, MD and Albert Lee*, MD

Department of Neurosurgery, Indiana University School of Medicine
Goodman Campbell Brain and Spine,
Indianapolis, IN, US

By the nature of its use, the intrathecal baclofen pump is frequently implanted in children and adults with either an advanced spinal, pelvic or hip deformity who suffer from muscle spasticity. These deformities often lead to additional surgical procedures either simultaneously or after the implantation of the baclofen pump and intrathecal catheterization. For example, when performing an operation on the hip ipsilateral to a previously implanted baclofen pump, the orthopedic surgeon may ask that the implanted intrathecal pump be removed, the wound temporarily packed off, with subsequent replacement of the pump at the end of the case. Prior standard techniques for dealing with the catheter and pump system during this type of operation are not advisable with the new Medtronic Ascenda system, a pump system that is fully MRI compatible. Furthermore, spinal deformity surgery and its relation to the baclofen pump system must be well planned and implemented in order to prevent a cerebrospinal fluid (CSF) leak, inhibition of fusion and spinal instrumentation breakdown. In this chapter, we will describe each of the aforementioned scenarios and surgical maneuvers for mitigating complications and improving outcomes in this patient population.

Intrathecal catheterization for intrathecal drug delivery (IDD) of baclofen has become the standard of care for patients with medically refractory spasticity and dystonia secondary to congenital or acquired neurological abnormalities [1, 3, 5, 6]. Baclofen pumps are frequently implanted in children and adults with advanced spinal, pelvic and hip deformity to relieve spasticity encountered in cerebral palsy and other congenital or acquired syndromes of cerebral or spinal origin [7]. The implantation of baclofen pumps in patients with cerebral palsy has been shown to reduce the overall need for lower extremity orthopedic procedures

* Corresponding Author's Email: alee@goodmancampbell.com.

post-operatively, including procedures considered necessary prior to implantation of the baclofen IDD system [4]. Unfortunately, baclofen pump implantation does not completely remove the need for additional orthopedic surgical procedures occurring either simultaneously or after the implantation of the baclofen system. Given that orthopedic procedures are common following baclofen IDD system implantation, it is prudent to cover the stepwise operative techniques to reduce the risk of complications and operative failure.

At our institution, we utilize the Medtronic Ascenda catheter and Synchromed II pump system for intrathecal catheterization and drug delivery. It is MRI compatible without surgically removing the mechanical pump. The Ascenda catheter is an extremely durable catheter that rarely fractures, occludes or disconnects from the pump, thus helping to reduce the occurrence of catheter related complications. Prior studies have indicated that catheter related post-operative complications are the most common complications following IDD system implantation, with a rate of up to 20% at 5 years [10]. Unfortunately, the increased durability of the catheter has resulted in a higher number of CSF leaks secondary to the inability of the dura to form a water tight closure around the dura. As such, the risk of CSF leaks when implanting or revising the catheter are significantly increased in comparison to prior systems.

BACLOFEN INTRATHECAL DRUG DELIVERY IN MAJOR DEFORMITY SURGERY FOR SCOLIOSIS

There are a number of caveats and nuances when attempting a long segment deformity operation in patients with scoliosis and baclofen pumps previously placed for refractory spasticity. While baclofen pumps clearly help to relieve significant spasticity, they do not necessarily inhibit the progression of scoliotic deformity and in some instances, may increase the rate of progression of the underlying disease process [2]. In addition, previously implanted intrathecal catheters will increase the complexity of the deformity operation. Prior studies have shown an increased rate of post-operative complications in cerebral palsy patients undergoing deformity correction with prior baclofen pump implantation as compared to cerebral palsy patients without baclofen pumps. This increased complication risk also holds for patients receiving concomitant baclofen IDD systems at the time of their deformity operation. Multiple studies have indicated that patients with baclofen pumps are at an increased risk for CSF leaks [2, 8]. In addition, patients with baclofen IDD systems are at increased risk for re-operation stemming from CSF leaks, deep spinal infections, and baclofen IDD system failures [8]. Many of these complications require complete explanation of the baclofen system, putting the patient at high risk for baclofen withdrawal, and, as such, are life threatening.

When performing a spinal deformity operation, it is important that the spine surgeon coordinate with the surgeon who implanted the IDD system. The surgeon who implanted the system should know what vertebral level the tip of the catheter is located and the vertebral level at which the catheter enters the spinal dura. During the deformity operation, every attempt should be made to maintain the intrathecal catheter in the thecal sac at the level it was originally placed. Migrating the catheter caudal or cephalad may result in changes to the therapeutic effect of baclofen and may require an additional surgery increasing the risk of

infection and pseudoarthrosis. In addition, if the catheter is accidentally extracted during the surgery it will need to be replaced immediately in order to prevent overt baclofen withdrawal. As such, the surgeon who implanted the pump should be made aware that an additional operation may be necessary, and working with a surgeon who is comfortable with open spine operations and baclofen catheters is highly recommended for these types of deformity operations.

The previous standard of care in deformity surgery with a previously implanted baclofen IDD system where the catheter was ligated or removed and then replaced at the end of the operation should not be performed with the Ascenda catheter because CSF leak rates are much higher than originally thought. While the Ascenda catheter is clearly more resilient than prior iterations of intrathecal catheters, it is not capable of reliably functioning with two metal sutureless connectors as this may cause a motion induced fracture secondary to stress/strain phenomena. Post-operative CSF leaks following major scoliosis deformity are extremely difficult to deal with and lead to an increased fusion failure rate and an increased risk of infection, see Figures 1 and 2 displaying a large, persistent CSF leak in a young patient after deformity scoliosis surgery where the Ascenda catheter was placed and ligated during the operation.

Figure 1. Axial CT slice showing a failed arthrodesis secondary to a persistent and large CSF leak stemming from a tied off intrathecal catheter. The osseous fusion has completely failed as it has been pushed out to the periphery (posterior and lateral) due to the large CSF leak.

The initial dissection to visualize and free the IDD catheter can be done with standard surgical technique using bovie electrocautery. The catheter will not be harmed if careful dissection is performed with dull instrumentation, e.g., sharp instruments and instruments with teeth should be avoided and bovie electrocautery should be utilized. The increased risk of CSF leak with the Medtronic Ascenda system is largely due to the inability of the dura around the inelastic Ascenda catheter to heal quickly enough to prevent the formation of a pseudomeningocele. It must be emphasized that CSF leaks with the Ascenda catheter are often resistant to traditional management techniques, e.g., bed rest, hydration, epidural blood patches, and complex surgical repair are often required to adequately seal the leak.

Figure 2. Sagittal reconstruction of the patient's CT scan displaying the osseous graft failure secondary to a large CSF leak. Note the significant posterior displacement of the graft material identified as the posterior hyperdensity.

Furthermore, the epidural blood patch, an often-utilized method for sealing a CSF leak is not a universally safe option following major deformity surgery for scoliosis. In total, these complications can result in the inhibition of osseous fusion, spinal instrumentation breakdown, and breakdown of the surgical wound with an increased rate of infection. The benefit of the Ascenda catheter system is that it has an extremely low occlusion rate, which does help with closure when removing old catheters and greatly reduces the risk of patients going into frank baclofen withdrawal. For these reasons, the authors highly recommend this system as the primary equipment in treating medically refractory spasticity over other available products.

ORTHOPEDIC HIP SURGERY FOLLOWING BACLOFEN PUMP PLACEMENT

Hip dysplasia is common in patients with cerebral palsy and the occurrence increases with increasing neurological involvement [9]. When performing an operation on the hip ipsilateral to a previously implanted baclofen pump, the orthopedic surgeon may ask that the implanted intrathecal pump be removed, the wound temporarily packed off, with subsequent replacement of the pump at the end of the case. This occurs in patients with spasticity and hip dysplasia that are small in stature and height as the pump or catheter may reside or pass

within the orthopedic surgeon's surgical field. Previously, the intrathecal catheter would be ligated prior to the orthopedic section of the case and then reconnected with a simple connector. Unfortunately, the Ascenda catheter, although more resilient, is not capable, of reliably functioning after being severed and reconnected. In addition, placing an Ascenda catheter and trying to ligate the catheter off, for future access to connect it to a pump in a delayed fashion may result in a constant CSF leak due to the catheter having an almost 0% occlusion rate. There is also an increased risk of catheter fracture with two sutureless metal connectors as noted above. As such, the pump must be removed and replaced after the conclusion of the orthopedic procedure. A case study is outlined below to further elicit the technical nuances and concerns for patients with baclofen pumps who require orthopedic intervention.

A 22-year-old male with a past medical history significant for cerebral palsy, bilateral hip dysplasia, and prior left sided baclofen pump placement was brought to the operating room for a left hip periacetabular osteotomy. A pre-operative pelvic X-ray showing prior right sided pelvic hardware, left sided femoral instrumentation and a left sided baclofen pump is shown in Figure 3. First, the patient was positioned for the orthopedic procedure, Figure 4. Next the patient is prepped and draped in the usual sterile fashion for the orthopedic procedure. Note that the abdominal pump pocket is also prepped and draped to allow for sterile removal and packing, Figure 5. Prior to the orthopedic segment of the operation, the abdominal pump incision is carefully opened and then bluntly dissected down to the pump. Every effort should be made to ensure that the catheter is not fractured or otherwise violated due to the aforementioned risk with catheter reconnection and distal ligation. Similar to deformity operations, the pump and catheter should be dissected out with blunt dissection and bovie electrocautery. Once the pump and catheter are well visualized, the pump should be carefully removed from the wound and subsequently disconnected from the catheter. A pair of hemostats are then placed on the catheter to prevent leakage of fluid through the catheter and to prevent the catheter from migrating out of the surgical field. The wound is then packed-off with antibiotic soaked gauze until the conclusion of the orthopedic procedure. The synchromed II pump is placed antibiotic solution until it is time to replace it in the patient, Figure 7. As shown in Figure 8, it is sometimes the case that the catheter may take a looping trajectory to the intrathecal space resulting in the catheter traversing the orthopedic wound. As such, the surgeon should not dissect the orthopedic wound with impunity, even after the baclofen pump has been removed, as there is still the potential for catheter injury. As previously mentioned, the Ascenda catheter is very resilient but may not withstand sharp dissection. Furthermore, the catheter is not always amenable to reconnection and fracturing the catheter at this point may necessitate the complete explantation and re-implantation of the entire system for reasons mentioned previously.

At the conclusion of the orthopedic procedure, the wound is reopened, the sterile packing is removed and the catheter with hemostat clamps is visualized. The catheter is cut within 1 cm proximal to where the hemostats were placed. The baclofen pump is then reconnected to the catheter. The pump is then placed back in the wound and sutured to the fascial layer. Antibiotic irrigation is then used to completely sterilize the wound and prevent infection. The wound is subsequently closed in the usual fashion. The pump in this case would need to be reprogrammed to reflect the operative changes made.

Figure 3. Pre-operative X-ray displaying the patients left sided baclofen pump and prior orthopedic instrumentation.

Figure 4. The patient is prepped and draped in the usual manner for the orthopedic procedure with the added caveat that the incision for baclofen pump is included within the field.

Figure 5. A skin incision is made over the previous pump incision. Blunt dissection is then used to identify the pump and catheter.

Figure 6. The catheter is identified and carefully manipulated so as to prevent fracture of the catheter. The catheter is then removed.

Figure 7. The pump is completely removed from the wound and washed with antibiotic solution.

Figure 8. A section of the baclofen catheter is shown running through the orthopedic wound. The orthopedic wound is inferior to the pump wound and is in a horizontal orientation.

KEY POINTS

- Open partial laryngectomies include: vertical partial laryngectomy and horizontal partial laryngectomy.
- Indications of supraglottic laryngectomy are: 1) lesions confined to the epiglottis and false vocal folds, 2) limited involvement of the aryepiglottic fold and 3) good pulmonary function.
- Indications for supracricoid laryngectomy include bilateral involvement of the vocal folds, minimal involvement of the anterior commissure, impaired mobility of the cords, T3 glottic lesions with minimal subglottic extension, and T4 tumors with limited thyroid cartilage invasion.
- Indications subtotal laryngectomy include glottic cancer (T2, T3) with significant subglottic extension reaching up to the cricoid cartilage.

Keywords: vertical partial laryngectomy, horizontal partial laryngectomy, supraglottic laryngectomy, supracricoid partial laryngectomy, subtotal laryngectomy with tracheohyoidopexy or tracheohyoidoepiglottopexy

INTRODUCTION

The beginnings of laryngectomy can be traced from the works of Solis-Cohen, Theodore Billroth, Gluck, Fraenkel, and Killian in the late 1800 and early 1900. During these early times, the survival rate after laryngectomy was 50% or less—mainly attributed to unsanitary surgical conditions. Mortality rate in the 1900's then decreased to 13% through the development of aseptic techniques and further refinement of the laryngectomy procedure. Particularly, laryngeal conservation surgery was introduced. Buck (1875) and Solis-Cohen (1868) in the US, Semon (1894) and Butlin (1895) in the UK, Okada in Tokyo, and Bruno in Germany were all early proponents of partial surgery [1]. The modified partial laryngectomy for anterior commissure was described by Clerf in 1940 and bilateral thyrotomy by Kemler in 1947 [1]. Frontolateral partial laryngectomy was promoted in France by Leroux-Robert in 1950–1970s [1]. Supraglottic surgery and hemilaryngectomy were among the first refined laryngeal conservation surgery techniques introduced by Justo Alonso in 1946 and Ogura in 1955, respectively [2]. Supracricoid partial laryngectomy (SCPL) was introduced by Majer and Reider in Vienna in 1959 [2]. Picquet gave more details of SCPL with cricothyoidoepiglottopexy (CHEP)/cricothyoidopexy (CHP) in 1986, and different pioneers including Laccourreye and Brasnu further exposed the technique to the world in 1990 [2]. Conservation procedures for laryngeal cancer became more widely used until CO₂ laser resection was eventually introduced in 1966 by Jako and Kleinsasser. The use of CO₂ laser and SCPL reached their peak in the 1970's. Furthermore, treatment for laryngeal cancer had become more holistic with the role of radiotherapy having been investigated upon from the early 1990's through many larynx preservation trials (e.g., EORTC, RTOG, GORTEC, EORTC) [3].

We have come a long way from the time of Prof. Billroth and Solis-Cohen. Advances in surgical treatment of laryngeal cancer such as conservation laryngeal surgery procedures have further improved the quality of life of patients by preserving voice, in a good number of cases, without compromising survival. The surgical anatomy of the larynx is based on its skeleton and connective tissue barriers, the spaces delineated by these structures, and the soft tissue structures that include fat, musculature, vessels, nerves, and adnexa including the three laryngeal cartilages (epiglottis, thyroid, cricoid), hyoepiglottic ligament, thyrohyoid membrane, quadrangular membrane, conus elasticus, anterior commissure, and cricothyroid membrane [4].

The laryngeal framework of the larynx is compartmentalized, and this compartmentalization may be attributed to its unique embryology. The embryologic development of the larynx influences the pattern of metastatic spread of laryngeal cancer, and serves as the foundation for the principles of conservation surgery. The larynx develops from three branchial arches. Supraglottic structures are derived primarily from the buccopharyngeal primordium which develops from the third and fourth branchial arches. The glottis and subglottic areas are derived from the tracheobronchial primordium from the sixth branchial arch [4]. This serves

as the basis for supraglottic laryngectomy. The glottis is also vertically separated embryologically to left and right, thus serving as the basis for hemilaryngectomy.

TECHNIQUES

Open partial laryngectomies include: vertical partial laryngectomy (hemilaryngectomy); and horizontal partial laryngectomy, which include supraglottic laryngectomy, supracricoid partial laryngectomy with cricohyoidoepiglottopexy (CHEP) or cricohyoidopexy (CHP) and Subtotal Laryngectomy with Tracheohyoidopexy (THIP) or Tracheohyoido-epiglottopexy (THIEP). Laryngofissure with cordectomy has been completely replaced by Laser CO2 cordectomies (Transoral Laser Microsurgery, TLM).

1. Vertical Partial Laryngectomy (VPL): Hemilaryngectomy [5-7]

Indications and Contraindications

The indications for hemilaryngectomy include unilateral involvement of the vocal fold, non-involvement of the thyroid cartilage, non-involvement of the epiglottis and cricoid cartilage; and T1 and T2 glottic cancer. Contraindications for the procedure include involvement of the thyroid cartilage, bilateral involvement of the vocal folds, gross involvement of the arytenoid of the epiglottis or cricoid cartilage, or poor pulmonary function.

Technique

Make a horizontal incision at the midportion of the thyroid cartilage from the anterior border of the sternocleidomastoid (SCM). Develop the flap superiorly and inferiorly and separate the strap muscles in the midline to expose the thyroid cartilage 1 cm above the superior border and 1 cm below the inferior border. Cut the perichondrium 2 mm away from the involved side. Dissect free the perichondrium up to the posterior edge of the thyroid cartilage of the involved side. Draw a vertical line 2mm from the midline of the uninvolved side and cut the cartilage through and through from the upper to the lower edge of the thyroid cartilage. Open the thyroid cartilage like a book and with 3mm margin, cut the thyroid cartilage on the involved side preserving at least 0.5cm at its posterior edge. The specimen is taken out leaving the perichondrium intact then suture the perichondrium back to its original position (if there is too much space in the defect, you may insert a portion of the strap muscle underneath the perichondrium). Close the strap muscle to itself, put a penrose drain, and close the skin incision in layers.

Variants of Hemilaryngectomy

Modification is a frontolateral partial laryngectomy wherein the excision is extended to the other cord and the arytenoid cartilage in the involved side may be resected [5-6]. Another modification is the extended hemilaryngectomy wherein the excision may be extended to the pyriform sinus resulting in the removal of both the cricoarytenoid and thyroarytenoid muscles [5-6].

2. Horizontal Partial Laryngectomy (HPL)

1) Supraglottic Laryngectomy

Key Points

- The cut in the thyroid framework should not be midline.
- Avoid fracturing the thyroid cartilage.

Indications and Contraindications

Indications are as follows: 1) lesions confined to the epiglottis and false vocal folds, 2) limited involvement of the aryepiglottic fold and 3) good pulmonary function. Contraindications include involvement of the paraglottic space inferiorly, gross involvement of the valleculae and the base of tongue, and poor pulmonary function.

Technique

Make a horizontal incision at the midportion of the thyroid cartilage from the anterior border of the sternocleidomastoid (SCM) on both sides (if neck dissection needs to be done, an apron incision or U-incision may be done). Flaps are developed up to 1cm above the hyoid bone. The suprahyoid muscles are released, and the infrahyoid strap muscles are also released close to their insertion (Figure 1). The external perichondrium of the thyroid cartilage is then freed along the superior and lateral aspects of the thyroid lamina on the affected side (Figure 2). The thyroid cartilage is cut horizontally midway between the superior and inferior borders of the thyroid cartilage (Figure 3). The suprastructure is then removed after the pharynx is entered just above the superior border of the thyroid cartilage (Figure 4). Closure is done through approximation of the perichondrium of the thyroid cartilage. The remaining thyroid cartilage is sutured to the hyoid bone (Figure 5) or to the tongue base (if the hyoid bone is resected). Penrose drain is placed and closure is done in layers. A tracheostomy tube is placed around 2 cm above the sternal notch.

2) Supracricoid Partial Laryngectomy (SCPL) [8-9]

Key Points

- Use an oscillating saw if possible to cut the thyroid cartilage horizontally.
- There should be no tension in the apposition with the remaining thyroid cartilage to the hyoid bone or the base of tongue. The patient should therefore be placed on flexed position.
- Tracheostomy site is separate from the surgical incision.

Figure 1. Suprahyoid muscles released, infrahyoid strap muscles released close to their insertion.

Figure 2. External perichondrium of the thyroid cartilage freed along the superior and lateral aspects of the thyroid lamina on the affected side.

Figure 3. Thyroid cartilage cut horizontally midway between the superior and inferior borders.

Figure 4. Suprastructure removed after the pharynx is entered just above the superior border of the thyroid cartilage.

Figure 5. Remaining thyroid cartilage sutured to the hyoid bone.

Indications and Contraindications

Indications for supracricoid laryngectomy include bilateral involvement of the vocal folds, minimal involvement of the anterior commissure, impaired mobility of the cords, T3 glottic lesions with minimal subglottic extension, and T4 tumors with limited thyroid cartilage invasion. Contraindications include pre-operative evidence of severe pulmonary impairment, involvement of the cricoid cartilage, involvement of the hyoid bone, significant pre-epiglottic space involvement, fixation of both arytenoid cartilages, and invasion of the outer perichondrium of the thyroid cartilage.

Technique

Make a horizontal incision at the midportion of the thyroid cartilage from the anterior border of the sternocleidomastoid (SCM) on both sides (if neck dissection needs to be done, an apron incision or U- incision may be done) (Figure 6). Cut strap muscles close to their insertions and flap them down. Cut the inferior constrictor muscles parallel to the posterior edge of the thyroid cartilage, just 0.5cm above it. Free the inferior horn (Figure 7) with care not to injure the recurrent laryngeal nerve. Do isthmusectomy and mobilize the thyroid

cartilage up to the level of the carina. Separate the cricoid cartilage from the inferior border of the thyroid cartilage (Figure 8). Reinsert the tracheostomy tube at the cricothyroid incision (Figure 9). Enter the valleculae via an incision just below the hyoid bone. With the use of Metzembaum scissors, start cutting at the uninvolved side with 3mm margin moving from superior down to the inferior portion up to the lower edge of the thyroid cartilage. Crack open like a book the thyroid cartilage for direct visualization of the lesion and cut free the thyroid cartilage on the other side with a 3mm margin. After resection of the tumor and the involved thyroid cartilage, the remaining cricoid cartilage and hyoid bone can be visualized. Subsequent suturing and impaction of the hyoid bone to the cricoid cartilage is done with Vicryl-0 (one in the midline, the other 1cm from the midline to the left, and another 1cm to the right) (Figure 10). If there is still tension, you may do a suprahyoid release (which will give an additional 1.5cm length). There are two ways of reconstructing the neoglottis: 1) CHEP- cricohyoido-epiglottopexy: done when the cricoid is impacted to the hyoid with epiglottis still intact, and 2) CHP- cricohyoidopexy: done when the cricoid is impacted to the hyoid bone without an epiglottis. A penrose drain is placed and strap muscles are reanastomosed using Vicryl 3-0. Skin closure is done in layers. A tracheostomy tube is placed around 2 cm above the sternal notch.

Figure 6. Horizontal incision made at the midportion of the thyroid cartilage from the anterior border of the sternocleidomastoid (SCM) on both sides; cricoid and thyroid cartilage are marked.

Figure 7. Inferior horn of the thyroid cartilage freed.

Figure 8. Inferior horn of the thyroid cartilage freed.

Figure 9. Reinsertion of the tracheostomy tube at the cricothyroid incision.

Figure 10. Subsequent suturing and impaction of the hyoid bone to the cricoid cartilage done with Vicryl-0 (one in the midline, the other 1cm from the midline to the left, and another 1cm to the right).

3) Subtotal Laryngectomy with Tracheohyoidopexy (THIP) or Tracheohyoidoepilgottopexy (THIEP)

Key Points

- There should be total removal of the thyroid cartilage.
- Ensure preservation of the recurrent laryngeal nerve.
- Ensure preservation of at least one arytenoid cartilage.
- Perform careful mobilization of the trachea.
- Impaction of cricoid/ trachea to the hyoid bone should be without tension.
- Suturing of cricoid to hyoid bone should be submucosal, ensuring that the epiglottis (if preserved) is well-anchored.
- Tracheostomy site is separate from the surgical incision.
- Use an oscillating saw if possible.
- Perichondrium must be preserved.
- Tracheostomy should be done in a separate incision.

Indications and Contraindications

The technique involves extending laryngeal resection beyond the limits of supracricoid laryngectomy. Indications include glottic cancer (T2, T3) with significant subglottic extension reaching up to the cricoid cartilage. An important contraindication is pre-operative evidence of severe pulmonary impairment.

The procedure entails resection of the cricoid cartilage but with preservation of the epiglottis if uninvolved, maintaining one or two cricoarytenoid units, and further suspension of the tracheal stump to the epiglottis and hyoid bone, or the hyoid bone alone.

Technique

Make a horizontal incision at the midportion of the thyroid cartilage from the anterior border of the sternocleidomastoid (SCM) on both sides (if neck dissection needs to be done, an apron incision or U-incision may be done). Cut strap muscles close to their insertions and flap them down. Cut the inferior constrictor muscles parallel to the posterior edge of the thyroid cartilage, just 0.5cm above it. Free the inferior horn with care not to injure the recurrent laryngeal nerve. Do isthmusectomy and mobilize the thyroid cartilage up to the level of the carina (See representative photos under supracricoid laryngectomy). The superior limit of the tumor is identified. If a THIP is to be performed, the pre-epiglottic space is removed by detaching the periosteum of the hyoid bone in its inferior portion to reach the mucosa of the vallecula, and the epiglottis is grasped and resected before performing pharyngotomy [10]. If a THIEP is to be performed, the pre-epiglottic space is incised along the superior edge of the thyroid cartilage and the epiglottis is preserved. The lower part of the resection involves separation of the cricoid ring from the trachea [10].

Tracheostomy is performed below the lower limit of the tumor, the endotracheal tube is reinserted through the tracheostomy and the resection proceeds differently according to whether one or two cricoarytenoid units are to be preserved [10]. If both cricoarytenoid units are to be preserved, suspension of the trachea to the hyoid bone is performed using five

double polyglactin suture stitches passed through the first and second tracheal ring (for THIEP), or through the pre-epiglottic space and through the base of the tongue encircling the hyoid bone (for THIP) [10]. The first stitch passes along the midline reaching to within 1 to 2 cm of the base of the tongue, whereas the lateral stitches should pass in front of the posterior cricoid plate through the base of the tongue close to the hyoid bone [10]. If only one cricoarytenoid unit is to be preserved, the pyriform fossa is reconstructed on the side of the sacrificed arytenoids before suspension of the trachea [10].

A Proposed Classification for Horizontal Partial Laryngectomy (HPL)

One of the advantages of supraglottic, supracricoid, and supratracheal laryngectomies is the possibility to customize the procedure to the specific extent of the disease, shifting from one HPL type to another intraoperatively. In extreme cases, in patients with a prior complete preoperative diagnostic workup, the procedure can be converted to a total laryngectomy intraoperatively. This results in a radical change in the patient's lifestyle after surgery and may lead to medicolegal issues regarding informed consent. To overcome these problems, a new classification of HPL has been proposed by the working committee on nomenclature of the European Laryngological Society, based on the craniocaudal extent of laryngeal structures resected (Table n°1) [11]. This could help the surgeon to refer to a surgical plan rather than to a single procedure, in the approach to HPL [12]. The proposed HPL classification system considers three types of partial horizontal laryngectomies: Type I (supraglottic), Type II (supracricoid) and Type III (supratracheal). HPL Type I can be extended to one arytenoid (A), the base of tongue (B), one vocal cord (C) or to a pyriform sinus (D); HPL Type II (a: with cricohydoepiglottopexy or b: with cricohyoidopexy) can be extended to one arytenoid (A); HPL Type III (a: with cricohydoepiglottopexy or b: with cricohyoidopexy) can be extended to one crico-arytenoid unit (A). This classification reflects and clarifies the complexity of HPL. All the possible HPL variations, in terms of extent of resection, are now clearly defined and can be reported in the informed consent.

Table 1. HPL classification proposal

TYPE I HPL: SUPRAGLOTTIC LARYNGECTOMY	TYPE II HPL: SUPRACRICOID LARYNGECTOMY	TYPE III HPL: SUPRATRACHEAL LARYNGECTOMY
TYPE I + A: extended to one arytenoid	TYPE IIa HPL: SUPRACRICOID LARYNGECTOMY with CRICOHYOIDO-EPIGLOTTOPEXY	TYPE IIIa HPL: SUPRATRACHEAL LARYNGECTOMY with TRACHEOHYOIDO-EPIGLOTTOPEXY
TYPE I + B: extended to base of the tongue	TYPE IIa + A HPL: SUPRACRICOID LARYNGECTOMY with CRICOHYOIDO-EPIGLOTTOPEXY extended to one arytenoid	TYPE IIIa + A HPL: SUPRATRACHEAL LARYNGECTOMY with CRICOHYOIDO-EPIGLOTTOPEXY extended to one arytenoid
TYPE I + C: extended to one vocal cord	TYPE IIb HPL: SUPRACRICOID LARYNGECTOMY with CRICOHYOIDOPEXY	TYPE IIIb HPL: SUPRATRACHEAL LARYNGECTOMY with CRICOHYOIDPEXY
TYPE I + D: extended to one pyriform sinus	TYPE IIb + A HPL: SUPRACRICOID LARYNGECTOMY with CRICOHYOIDOPEXY extended to one arytenoid	TYPE IIIb + A HPL: SUPRATRACHEAL LARYNGECTOMY with CRICOHYOIDOPEXY extended to one arytenoid

Chapter 436

EFFECT OF BARIATRIC SURGERY ON WEIGHT AND DIABETES

Natalia R. Moreno-Castellanos*, PhD

Department of Basic Sciences, Universidad Industrial de Santander,
Bucaramanga, Colombia

ABSTRACT

Bariatric surgery (BS) is a set of effective surgical procedures used for weight reduction and improvement of insulin sensitivity in morbidly obese patients, in comparison with non-invasive techniques such as drug treatment or changes in lifestyle. BS induces mechanical modifications, such as brain-mediated suppression of appetite, changes in gut hormones, microbiome and bile acids, which together, contribute to BS-associated improvement of glucose, lipid homeostasis and inflammation. Although the resolution of obesity-related metabolic comorbidities occurs well in advance of significant fat mass reductions, it is accepted that BS causes profound changes in the adipose tissue (AT) biology, which, in turn, strongly affect systemic glucose utilization and metabolic health leading to the improvement of insulin response in diabetic patients.

In this line, BS modifies the AT secretory profile and the expression of genes involved in the regulation of adipocyte metabolism, inflammation, and extracellular matrix organization, inducing adaptive changes in the AT. Notably, the degree of improvement, regarding to insulin sensitivity, after BS may depend on AT features at pre-surgery, such as adipocyte size and AT fibrosis; however, the reversion of insulin resistance strongly depends on the “pre-metabolic status” of individuals: “metabolically healthy obese” (MHO) or “metabolically unhealthy obese” (MUO).

Keywords: bariatric surgery, type 2 diabetes, weight, insulin sensitivity

INTRODUCTION

Over the last few decades, there has been a progressive increase in overweight and obesity, this tendency has become a serious problem for public health; mainly, because of its association with diseases, such as type 2 diabetes (T2D), cardiovascular diseases, hypertension, dyslipidemia among others [1, 2].

Obesity is a chronic, multi-factorial and recurrent disease, caused by abnormal or excessive fat accumulation, resulting in an altered metabolism and serious health consequences [3, 4] caused mainly by an imbalance between calories consumed and expended. Based on the Body Mass Index (BMI), the nutritional status of obese people can be classified as: overweight; BMI 30 to 34.9 kg/m², Grade I obesity; BMI 35 - 39.9 kg/m², Grade II obesity; BMI > 40 kg/m², Grade III Obesity or Morbid obesity, defined as a BMI higher than 40 kg/m² or 35 kg/m² [5].

In obesity, there is a lipid accumulation and hypertrophy of the adipocytes. Obese patients, with hypertrophic adipocyte, present a metabolic overload of intracellular and extracellular mechanisms (oxidation of energy substrates and protein synthesis, extracellular matrix expansion and angiogenesis), making them unable to meet metabolic demands. these mechanisms lead to: i) deficiencies in energy production and protein synthesis which, in turn, cause the activation of an intracellular inflammatory response, ii) endoplasmic reticulum (ER) stress and iii) increase in the mitochondrial production of ROS. The latter two, together with hypoxia and mechanical stress, generate the activation of inflammatory cascades (c-jun N-terminal kinase (JNK) and nuclear factor- κ B (NF- κ B)) [6, 7]. Those alterations lead to: an increase the overproduction of pro-inflammatory adipokines (tumor necrosis factor (TNF), interleukin 6 (IL-6), monocyte chemoattractant protein-1 (MCP-1)), decrease adiponectin, amplification of oxidative stress and mechanical stress, development of chronic inflammation and a decrease in insulin signaling, causing insulin resistance (IR).

IR obese patients develop all the metabolic alterations associated with obesity. These patients are called “metabolically unhealthy obese” (MUO) [8], however, not all obese patients develop metabolic complications and IR. There is a type of obese individuals with a normal phenotype, “metabolically healthy obese” (MHO), who interestingly, maintains insulin sensitivity [9]. Specifically, MHO individuals are 13-29% of the obese population [10]. Characterized by maintaining insulin sensitivity, they have a normalized pattern of adipokines (including normal adiponectin levels), a reduction of adipose tissue (AT) fibrosis, smaller adipocytes in contrast with MUO adipocytes, a decrease in AT macrophage infiltration, a low inflammatory and lipid profile, and fasting glucose within normal ranges compared to MUO individuals [11-13]. These phenotypic features reduce the development of dyslipidemia, hypertension, IR, T2D, cardiovascular disease and, ultimately, metabolic syndrome.

There are different strategies to reduce obesity and pathologies associated therewith, the most common of which are reduction methods, such as diet and exercise. Both, improve body fat and body mass index, increase free fatty acids (FFA) oxidation, improve insulin sensitivity and glucose tolerance, have favorable effects on lipid profile, reduce hypertension and inflammation, increase adiponectin levels and reduce the basal levels of damage caused by oxidants [14]. Other common methods are drugs therapies (Omega-3 fatty acids, metformin,

inhibitors of angiotensin, etc.). These methods also promote weight loss and improve patient health, mainly relating to dyslipidemia and hypertension.

Interestingly, although the benefits of these methods in many cases are unsatisfactory. Actually, bariatric surgery (BS) is an effective treatment option for sustained weight loss, this medical procedure improves: hypertension, dyslipidemia, inflammatory status and reverts in the long term IR in obese patients (BS reverses IR and T2D in many patients in proportion to weight loss) [15],

Several studies consider that the improvement of IR may be associated with the remaining volume of the proximal stomach and malabsorptive state, BS caused metabolic changes in the intestine and the transit of food, including changes in the levels of gut hormones (glucagon-like peptide - 1 (GLP - 1) and peptide YY (PYY)), which positively affects insulin and glucose homeostasis [16]. Understanding the mechanisms underlying obesity and BS as the best effective treatment to weight loss is important, particularly the effect on IR patients improving their insulin sensitivity.

BARIATRIC SURGERY AND WEIGHT LOSS

There are several strategies to promote weight loss, but BS, is an effective surgical procedure used to reduce weight and improve health in patients with morbid obesity [17, 18]. These procedures are indicated mainly in obese patients with BMI ≥ 35 kg/m² and in which drug treatment and lifestyle modification have not been successful [19, 20].

BS surgical procedures are classified as restrictive, malabsorptive or mixed techniques. Restrictive methods consist of reducing size or gastric capacity, limiting food intake. Meanwhile, malabsorptive methods involve decreased absorption of nutrients by removing parts of the small intestine. Mixed methods combine both restrictive and malabsorptive techniques. The four techniques most used in BS include: adjustable gastric banding (restrictive technique, placing a band around the upper stomach), sleeve gastrectomy (restrictive technique, reducing stomach size by 25%), gastric bypass surgery (mixed method, creating a small stomach pouch, which can only contain small amounts of food and, in turn, connecting the small intestine to the stomach, thus reducing nutrient absorption) and biliopancreatic diversion (mixed technique, which reduces the stomach and creates a stomach pouch).

The effect of weight loss caused by BS is dependent on factors other than the BS method used. Those factors include, social factors such as age, gender, race, body composition, education, emotional state and activity [21]. Another factor that helps weight loss is the modification of the diet to prevent weight regain after BS [21]. All these factors lead to variations in the grade of weight loss between different patients. However, despite variations in weight loss among patients, patients lose weight significantly at 2 years, followed by a gradual weight reduction in the following years as a result of hormonal, cellular, metabolic and gene changes produced in response to the BS.

It has been suggested that acute caloric restriction that occurs just after BS with increases in some peptides associated with satiety (GLP-1, PYY, oxyntomodulin, gastrin) and decrease in factors associated with feeling hungry (ghrelin) promote weight loss [16]. Notably, it has been established that weight loss associated with BS induces changes in the AT which, in

turn, have a significant impact on the peripheral and general use of glucose and metabolic health [22, 23].

There have been a number of studies that have shown that BS induces important changes in the secretory profile of the AT, reflected in the weight loss [24]. Specifically, adiponectin increases significantly in relation to weight loss in patients undergoing BS, while leptin levels have been reduced. These changes have also been correlated with improved insulin resistance and normalization of the lipid profile in patients after surgery [23], indicating a recovery of alterations in the development of obesity in AT. Additionally, there have been studies that show both an increase [24] or decrease [25] in the pro-inflammatory cytokine tumor necrosis factor- α (TNF- α) after BS. The increase is due to the persistent inflammation after gastric bypass surgery, while decreasing TNF- α is explained by weight reduction and therefore, a reduction in the proinflammatory profile.

There are few studies about cellular and molecular changes that accompany weight loss after BS, especially in the medium and long term, but, they are not yet fully clarified mechanisms and molecular pathways involved in this process and, in particular, those that might contribute to improve the metabolic profile of obese patients undergoing BS. Specifically, a transcriptomic study by Dankel et al. showed an increase in expression of genes involved in pathways associated with the regulation of energy metabolism, as well as important gene changes related to the extracellular matrix after BS [26]. Other target studies have shown that weight loss after BS brings increase of proteins associated with lipid droplets, as CIDEC/FSP27, perilipin 1 (PLIN1), or lipogenic and mitochondrial genes [27].

Moreover, after BS, there are significant morphological changes, specifically in adipocyte size and/or related to the cytoskeleton, which greatly affect glucose utilization and/or fibrosis [28, 29]. This change in adipocyte size, after BS, is accompanied by cellular remodeling, which, in turn, involves cytoskeletal changes. In fact, although this field is not extensively studied, weight loss modifies some cytoskeletal proteins such as: vimentin, tubulin and actin, which in turn helps to normalize the metabolism [30] and increase adipogenesis in AT [31]. These changes, together, promote normalization of adipocyte functionality and thus promote weight reduction.

BARIATRIC SURGERY AND DIABETES

BS leads to improvement of blood sugar and remission of insulin resistance in patients with T2D, even before there have been significant reductions in weight [32]. Generally, short-term remission of diabetes occurs in 60-90% of patients. These ranges cannot be generalized to long-term results. Sjöström et al. published a prospective study in 25 surgical departments and 480 primary care centers in Sweden, called the study “Swedish Obese Subjects” (SOS), in order to determine the ranges of diabetes remission after BS compared to usual medical treatment after 10 and 18 years. The diabetes remission two years later was 16.4% in patients with medical control and 72.3% in patients after BS. At age 15, ranges remission of diabetes decreased to 6.5% for patients with medical management and 30.4% for patients undergoing BS [33]. Additionally, Buchwaldy et al. in a meta-analysis of 136 studies and 22,094 patients, compare different BS methods and found that, regardless of the procedure, BS improves or solves diseases such as T2D, hypertension and dyslipidemia in more than 80% of obese

patients [34]. Sugerman et al. in a study of 1,025 patients undergoing gastric “bypass”, 2 years after BS, 83% of diabetic patients had fasting glucose of less than 120 mg/dl without the use of antidiabetic drugs [35].

Due to the existence of a large number of studies that support the effect of BS on diabetes remission and therefore, improving insulin sensitivity, clearly BS induces an improvement in remission of diabetes in the short term compared to other clinical methods. Restrictive methods, such as adjustable gastric band, show lower remission rates of diabetes and have an effect on glucose metabolism related to weight loss. Nevertheless, more complex procedures, such as, gastric bypass, alter the anatomy and neuroendocrine function. This surgery has higher remission rates even before weight loss, suggesting the presence of other mechanisms probably related to biochemical or endocrine disruption. The improvement in diabetes due to BS has been attributed to caloric restriction, changes in gut hormones, mechanical changes of the gastrointestinal system, appetite suppression mediated by changes in the central nervous system, and/or changes in the composition of bile acids and microbiota, adipose tissue modifications and metabolic status of subjects (MHO vs. MUO) before BS, taste receptors of the gut, genetic factors, insulin clearance and amino acids [36, 37].

Caloric Restriction

It is well known, that caloric restriction significantly improves glucose tolerance in diabetic patients. BS has been associated with improvements in fasting glucose and insulin signaling, occurring frequently in a short time after BS and even before significant weight loss. Obese patients undergoing BS or dieting at 500 kcal/day lose a similar amount of weight during the first 3 weeks and exhibit similar improvements in insulin sensitivity, acute secretion of insulin and beta cell action [38]. This mechanism partly explains remission of diabetes, which is common in all bariatric procedures. However, similar caloric intakes, decrease faster glucose plasma levels in procedures such as gastric bypass comparing with restrictive methods.

Glucagon and Glucagon-Like Peptide 2(GLP2)

Glucagon is a mechanism that improves glucose homeostasis after BS because it increases after stimulation by food in a postprandial state after gastric bypass. However, one year after gastric bypass and after fasting decreases, it could explain some of the long-term benefits of gastric bypass on glucose metabolism.

On the other hand, GLP-2 regulates gastric motility, gastric acid secretion, intestinal transport of hexose, glucagon secretion; increases absorption area and increase barrier function of the intestinal epithelium through inhibition of apoptosis in the enterocyte and crypt cell stimulation and proliferation. Rats' GLP-2 levels after bypass increase, which has been associated with high proliferation of crypt cells as early as 23 days after surgery. This clarifies how well the gastric bypass is tolerated and the low degree of macronutrients malabsorption [39]. However, the association of GLP2 with improved homeostasis after gastric bypass is not yet fully understood.

Incretins

Several studies have shown GLP-1 increase after gastric bypass, but not after adjustable gastric banding, weight loss or diet-induced. The GLP-1 increase is clearly related to the gastrointestinal anatomy alteration caused by the gastric bypass method [16, 40]. The early recovery of beta cells function has been associated with a higher GLP-1 secretion after-gastric bypass, although the cause has not yet been determined [41]. Studies about GIP changes after-BS have been inconsistent. In theory, the removal of duodenum, where most K enteroendocrine cells producing GIP are located, would lead to decreased GIP secretion after gastric bypass [42]. Instead, some studies have found increases in GIP [43], while in others have found decreases [42]. It is possible because different GIP secretion levels after surgery could be caused by variations in surgical technique, specifically, differences in the length of the Roux anastomosis, and blood sampling time.

Changes in Appetite Hormones

PYY is a polypeptide like GLP-1, found in L cells in the gastrointestinal tract, especially in colon and ileum. PYY function is primarily inhibitory, including stomach acid secretion, stomach emptying, intestinal transit rate, insulin secretion and exocrine pancreatic secretion. It also suppresses appetite and reduces food intake, promoting weight loss [44] and stimulating insulin activity [45]. PYY levels increased after gastric bypass, but not after adjustable gastric banding [46]. GLP-1 and PYY postprandial increase after BS, suggesting that gut hormones modulate appetite to enhance the sensitivity and insulin secretion, leading to reduction in food intake and contributing to achieving and maintaining better glycemia control [47].

Ghrelin is secreted by the gastric fundus and proximal small intestine. It acts on the hypothalamus, regulating appetite. Furthermore, it acts on the pancreatic islet where it is also produced, inhibiting insulin secretion. Ghrelin also stimulates appetite and reduces energy expenditure and fat catabolism. Among the mechanisms that regulate ghrelin secretion is body weight, which is inversely proportional to ghrelin amount, suggesting a major role in regulating long-term body weight. Several studies have reported decreases in ghrelin levels in fasting and postprandial post-gastric bypass; others have not found any change or even a low increase in ghrelin [48]. These apparently different results may be due to the post-surgery times studied, the amount of weight loss and sampling time (fasting vs. after meals).

Mechanical Changes of the Gastrointestinal System

One mechanism improving T2D after BS is the rapid delivery of nutrients not absorbed into the active distal intestine “ileal brake” that enhances the secretion of GLP-1 and PYY (hypothesis of the distal bowel). It is the most studied and probably one of the best theories supported by available evidence. It suggests that the arrival of nutrients to distal segments of the small intestine due to duodenum bypass and proximal jejunum, increases peptides secreted in the enteroendocrine “L” cells of the distal segments of the intestine (GLP-1 and PYY) [49]. This has been shown many times in experimental research, demonstrating high

levels of incretins after gastric bypass [46, 47]. It has also been shown, that patients in which ileal interposition is carried out, which locates rich ileal segments of “L” cells in proximal bowel segments, also have improved insulin sensitivity, improved glycemic control and plasma levels of GLP 1 and PYY, which further confirms the role of the stimulation of hindgut and confirms the role of distal intestine stimulation [50-52]. This effect (improvement in glucose metabolism and GLP-1 increased) also occurs after sleeve gastrectomy surgery, which does not include changes in the structure of intestinal transit, increases the rate of gastric emptying, which probably stimulates more distal segments of the small intestine. Ileal interposition in humans associated with gastrectomy has shown potential for the treatment of T2D in patients with BMI: 21-34kg/m² [53]. The exclusion of proximal nutrients in the small intestine (foregut hypothesis) has also been proposed as a euglycemia restorer. While gastric bypass nutrients promote exposure of the distal intestine, they also produce an exclusion of the proximal segments of the small intestine. Foregut theory suggests the existence of unknown hormones, whose effect would be antagonistic to incretins and insulin and would even promote insulin resistance [54]. This theory is based primarily on the results obtained with duodenal jejunal bypass; however, other studies with this procedure, do not have the same results in all animal models [55]. In addition, the results obtained with sleeve gastrectomy, in which these segments are not excluded, results similar to gastric bypass have found; this does not support this theory [56]. Less invasive endoscopic therapies have also been used for the treatment of T2D using a procedure of sleeve endoluminal in a rat model. Into the invasive therapies are included, gastric bypass, foregut bypass and early exposure to nutrients partially digested to the jejunum, Aguirre et al. showed that while rats undergoing gastric bypass surgery lost more weight than rats subjected to sleeve endoluminal, rats with sleeve endoluminal achieved greater improvement in glucose homeostasis [57]. In humans, they have shown reductions in glycated hemoglobin (HbA1c) subsequent to different types of endoluminal sleeves duodeno-jejunal. They are leading further research on safety, efficacy and long-term results.

Afipose Tissue and Metabolic Status of Subjects (MHO vs. MUO)

After gastric bypass, a significant weight and body fat reduction, including 50-60% reduction in visceral AT. Adiponectin, a protein of 244 amino acids secreted by white AT, is inversely proportional to body fat, BMI, waist-hip ratio, serum insulin and glucose levels [58], lower levels are closely related to insulin resistance and suspected to play a role in the pathogenesis of T2D. Many studies have shown an increase in adiponectin after gastric bypass, which is correlated with improvement in insulin resistance [59], adiponectin also increases in serum and AT levels after BS in both obese patients: MUO and MHO. These results together add further evidence to the beneficial effects of BS improving chronic systemic inflammation associated with obesity and insulin resistance [60].

On the other hand, metabolic conditions of patients after BS depend largely on AT characteristics of patients undergoing surgery. It has been established, that adipocytes size and degree of fibrosis before BS can affect the improvement of insulin resistance and reversion of T2D [28, 29]. In this regard, there are subtypes of obese individuals regarding the development of metabolic disease (MHO vs. MUO). It has been considered that to better understand the mechanism that improves insulin sensitivity after the BS, it is necessary to

explain the mechanisms underlying the maintenance of MHO phenotype. Some studies have failed at trying to attribute to changes in lifestyle (diet and physical activity) [61], while other studies have found that MHO individuals, in addition to maintaining insulin sensitivity, have greater capacity to adapt to calorie diets than MUO individuals [62]. Other studies have focused on explaining this phenotype by genetic modification [modification in some genes, such as adiponectin receptor 1 (AdipoR1) and hepatic lipase (LIPC)] [63] and other studies have attributed it to molecular changes in the AT. On the molecular level, it has been found that heat stress in MUO individuals leads to inflammation of AT and increased pro-inflammatory cytokines, hypertrophy, hyperplasia and AT dysfunction, while caloric overload in MHO individuals promotes hyperplasia, but does not increase adipocytes size, which is associated with the maintenance of a normal AT function and maintenance of insulin sensitivity [62].

Recently, our research group has shown that, compared to what was observed in obese MHO, the adipocytes of obese MUO individuals have less ability to prevent oxidative damage and excessive activity of the endoplasmic reticulum (i.e., ER stress) in obesity, this and proteasome dysfunction, carry an accumulation of oxidation and/or misfolding proteins in cells of MUO patients [64]. This proteasome dysfunction, which also occurs in animal models of insulin resistance and which can be induced in vitro by exposure to palmitate, is directly associated with the development of insulin resistance [64]. In addition, in another study we found that BS affects the AT of MUO and MHO in a different way. Moreno et al. determine the proteome of subcutaneous adipose tissue (SAT) in obese patients, with and without IR, before and one year after BS, to identify proteins that may be involved in metabolic changes in the AT. The AT of either MHO or MUO morbidly obese individuals exhibited proteomic signatures suggestive of functional recovery one year after surgery, yet there remained significant differences between the two groups of subjects at after BS, despite similar weight reductions, favorable adipokine profile and decreased inflammation. BS-induced weight loss evokes significant rearrangements in the metabolic activity, oxidative capacity, mitochondrial activity, cytoskeletal organization, and angiogenic capacity of AT in morbidly obese women. However, the most important part of this study is that surgery evokes selective changes in the AT of MUO morbidly obese subjects in a way that resembles, at least in some aspects, the AT in the MHO obese state, while MHO obese AT tends to acquire a lean-like phenotype. These phenotypic aspects of AT may be associated largely with the reversion of the T2D subjects in MUO after BS [60].

Bile Acids

Bile acids work as fat solubilizers and activate nuclear transcription factors that regulate genes involved in the metabolism of glucose and cholesterol. They can also activate TGR5, which is a receptor associated with a G protein activation, which regulates the secretion of GLP-1. Bile acids also act on Farnesoid X receptor, stimulating the secretion of fibroblast growth factor (FGF) 19 with subsequent inhibition of hepatic gluconeogenesis that result in the generation of glucose from certain non-carbohydrate carbon substrates. In prospective studies with humans and animals, Puornaras et al. conclude that gastric bypass but not the gastric banding, lead to faster delivery of bile acids into the terminal ileum, which causes an

increase in the total concentration of bile acids, plasma levels of GLP-1, PYY and FGF 19 [65].

Gut Microbiota

Recent data from studies in mice and small studies in humans have shown that the gut microbiota may play an important role in energy storage and in the development of obesity and associated complications [66]. BS, in particular, induces environmental, systemic and anatomical changes that may affect the composition of gut microbiota. Some studies suggest a change in intestinal microbiota after surgery to profiles most similar to lean subjects. However, these differences have also been found in obese patients undergoing low-calorie diets with restriction of carbohydrates or fats, so it is not clear whether the changes found after gastric bypass are secondary to the structural changes of the intestine, changes in hormone levels or due to diet after surgery [22, 66]. It remains to be clarified whether these changes in microbiota contribute to improving glucose homeostasis.

Genetic Factors

The melanocortin system is an integral component in the regulation of energy homeostasis. The loss of a single functional copy of the melanocortin receptor-4 gene (MC4R) is the most common mutation associated with obesity in humans. Mirshahi et al. found that subjects with I251L allele were more likely to lose weight during surgical and dietary interventions and had less insulin resistance. Published research on the role of MC4R in bariatric surgery involves few diabetic patients, so it is not clear whether MC4R has clinical significance in glycemic results [67]. Recently, fetal and adult ablation of transcription factor - Foxo1 in mouse enteroendocrine stem cells has led to the development of intestinal cells with the ability to produce insulin biologically active in response to glucose. In contrast to insulin-producing cells derived from embryonic stem cells, insulin-producing cells arising from the intestine showed a singular plasticity and ability to regenerate and produce insulin [68]. It is possible that BS, by changing hormonal signals and nutrients, have an influence on insulin secretion in the intestine through Foxo1 alterations.

Taste Receptors of the Gut

Taste receptors coupled with G-protein detect bowel luminal contents and send signals that regulate the expression of nutrient carriers and nutrient uptake, as well as release of gut hormones and neurotransmitters involved in the regulation of energy homeostasis and glucose. Sweet taste receptors, TAS1R2, have been altered in T2D and may increase the risk of postprandial hyperglycemia by increasing glucose uptake by cotransport Na⁺/glucose SGLT1 during hyperglycemia [69]. The fast discharge of undigested nutrients into the small intestine after gastric bypass can also affect the regulation of taste receptors or glucose transporters in L cells, leading to increased secretion of PYY and GLP-1 [70].

Insulin Clearance

The fast decrease in fasting glucose and fasting insulin after gastric bypass may be caused by an early improvement in hepatic glucose production and hepatic insulin sensitivity. Plasma FFA increases following BS are followed by a decrease in FFA plasma levels one year after BS, later contributing to the improvement of peripheral insulin sensitivity.

Amino Acids

Dietary macronutrients work as signaling molecules affecting eating behavior, enteric hormones, insulin release and sensitivity. Obesity and diabetes are known to alter the circulating levels of many metabolites. Metabolite profiles in diabetic patients have shown weight loss after gastric bypass, but not equal to weight loss induced by diet, which is associated with decreased plasma concentrations of fasting branched chain amino acids and their metabolites (C3 and C5) which correlate negatively with insulin sensitivity [71].

CONCLUSION

Bariatric surgery is as a treatment for sustained weight loss in morbidly obese subjects. Recently, development of new procedures and improved surgical techniques has found favorable results in T2D remission. In fact, the improvement of T2D with bariatric surgery reflects positive short- and long-term results. Nevertheless, among the different surgical techniques, gastric bypass clearly has the best results in weight loss and remission of diabetes. Although the results of bariatric surgery, in the management of T2D have been shown in many publications, the pathophysiological mechanisms are not fully understood. Nevertheless, the mechanisms considered important increasing sensitivity to insulin and weight loss include changes in caloric intake and glucose metabolism mediated primarily by changes in intestinal hormones released into specific segments, as well as genetic and mechanical mechanisms, AT modifications and clear differences between the initial metabolic states (MUO vs. MHO) of subjects before BS. The pathophysiological basics are constantly being researched and require further study for confirmation. However, it can be concluded that the improvement of diabetes and weight loss after BS implies a multifactorial complex process.

BIOGRAPHICAL SKETCH

Natalia R. Moreno-Castellanos

Education: MSc, PhD Biomedicine

Research and Professional Experience:

I obtained my MSc degree in Cell Biology, molecular and genetic at the University of Córdoba, Spain in 2010. I completed PhD studies at the University of Cordoba in 2015, under the supervision of Prof. Maria Malagón and Rafael Martinez, research based on the identification of new biomarkers of the adipose tissue in obesity and insulin resistance in a collaborative project between the Metabolic Research Laboratory of Navarra and the University of Córdoba. During this project, I applied different experimental techniques, which have allowed it to obtain original and new results on the effects of bariatric surgery on the molecular composition of adipose tissue and to identify and characterize for the first time, a new element of the cytoskeleton of adipocytes, in relation to the regulation of lipid metabolism, obesity and insulin resistance. These results have been collected in two publications one published at “Obesity Surgery” and other currently under review in the journal “Diabetes”. In addition, as a result of other collaborations I participated as co-author in different journals, such as: “Antioxidants Redox Signaling”, “Scientific Reports”, “Molecular and Cellular Endocrinology”, “Journal of Clinical Endocrinology and Metabolism” and “Current Vascular Pharmacology”. Actually I have a position as a professor full time at the University Industrial de Santander, Department of Cell Biology, Colombia), at the same time I being member of the research group of the Spanish network of excellence for obesity and nutrition (CIBERObn). My research line is now focused on the study of genetic aspects on Diabetes Mody and their impact on physiology and pathophysiology in Colombian people and Obesity and metabolic diseases and its association with infectious diseases. Finally, I

presented results in different national conferences (4 communications type Oral Poster) and international (2 Poster type and one oral communication).

Professional Appointments: Full time Professor

Honors

1. 2 Scholarship granted by the Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Spain for a research stay in:
 - Metabolic Research Laboratory, under Dr. Gema Frühbeck supervision. University of Navarra, Pamplona, Spain. January 5th –April 5th 2014.
 - Network of Excellence for Functional Biomaterials and in the Centre for Research in Medical Devices (CURAM), under Dr. Abhay Pandit supervision. National University of Ireland, Galway, Ireland. June 1 th–August 30th 2015.
2. 1 Travel Grant, granted by the European Obesity society (EASO), for an Oral Communication (Functional characterization of novel cytoskeletal protein SEPT11 in murine and human adipocytes: role in lipid traffic), Sweden, Gotheburg, June 1th-June 4th.

Department of Surgery, University Hospital Rey Juan Carlos, Spain

ABSTRACT

Obesity is actually considered as a global epidemic disease associated with high physical and psychological morbidity. Bariatric surgery has proven to be the most effective and definitive treatment for this entity. In general, obese patients have poor physiologic reserve and this, added to their voluminous anatomy, leads to the development of complications in a different way than patients with normal BMI. Even in the presence of peritonitis, obese patients do not show clear symptoms, such as fever or abdominal pain and, when present, the diagnosis can be achieved when it is too late. The only significant clinical finding, as described by Mason, is the rapid pulse or tachycardia over 120 bpm; when an obese patient presents it in the first days after surgery, it is mandatory to rule out two complications, that can cause death if they are not quickly treated. These complications are intra-abdominal sepsis, and massive pulmonary embolism. Mason recommended in the presence of tachycardia to assess and treat "before the sun sets", this is, to solve before it is too late. The key for a good outcome in the management of complications, is to have a high index of suspicion when our patient "is not doing well" after surgery and having a low threshold for reintervention. Based on the published series of bariatric surgery, complications can be classified as perioperative (up to 30 days after the operation); immediate postoperative period (up to 6 months) and late (after 6 months). Additionally, based on the severity of the complication, it can be classified as severe (requiring reoperation or resulting in death) or mild. In this chapter we will focus on peri, postoperative and late complications.

INTRODUCTION

Obesity is actually considered as a global epidemic disease associated with high physical and psychological morbidity. Bariatric surgery has proven to be the most effective and definitive treatment for this entity. In general, obese patients have poor physiologic reserve and this, added to their voluminous anatomy, leads to the development of complications in a different way than patients with normal BMI. Even in the presence of peritonitis, obese patients do not show clear symptoms, such as fever or abdominal pain and, when present, the diagnosis can be achieved when it is too late. The only significant clinical finding, as described by Mason, is the rapid pulse or tachycardia over 120 bpm; when an obese patient presents it in the first days after surgery, it is mandatory to rule out two complications, that can cause death if they are not quickly treated.

PERI AND POSTOPERATIVE COMPLICATIONS

Leaks

Leaks can occur in the anastomosis, the staple line, or in cases of diathermic or mechanical injuries with laparoscopic instruments. Leaks are the most feared complication of bariatric surgery. Initially, they present only with tachycardia or may associate leukocytosis, neutrophilia and increased C-reactive protein; symptoms and signs of sepsis may appear later. The same signs may also be present in the setting of pulmonary embolism. The risk of leak ranges from 0.8% to 6%, but might be increased up to 35% in revisional bariatric surgery. Most leaks occur early, generally within the first week after surgery, but can occur up to a month after the operation [1-3]. The diagnosis of this complication can sometimes be a challenge. When a leak is unnoticed, the septic state progresses and the patients rapidly develop respiratory and renal failure [4]. As a general rule and it is the policy that we follow at our institution, once a leak is clinically suspected, even in cases without radiological confirmation, a surgical exploration must be performed, by laparoscopic approach when possible. How to diagnose this complication? In the case of patients with drainage, a change in the characteristics of the fluid can be observed, with outflow of intestinal contents or purulent discharge. We can also give a swallow of methylene blue dye and in case of extravasation, the diagnosis is achieved. However, it is not always a valid tool for diagnosis, since not all patients have drainage or they do not collect the site of the fistula. Computed tomography with IV and oral contrast (gastrografin), is the best imaging technique for the diagnosis of leak, with a sensibility for the diagnosis that reaches up to 86% [5]. It also allows to diagnose or at least provides indirect data of leak location, as in leaks located in the gastric remnant after a Gastric Bypass, where it does not reach the contrast. Another test that can be performed is an esophagus-gastro-duodenal transit with gastrografin. In some high-volume centers, the transit is first performed with gastrografin, then with Barium and finally a CT scan is performed, increasing thereby the percentage of diagnosed leaks.

In unstable patients, the treatment of leaks consist in emergency surgery, with different options ranging from drainage of the fluid collections adjacent to the fistula, resuture of the

leakage point or resection of the anastomosis and confection of a new one. In addition the treatment should include:

- Broad-spectrum antibiotic coverage
- Enteral access for feeding, most commonly a gastric feeding tube placed in the gastric remnant.

In a stable patient, a non-operative management of leaks can be chosen, including IV antibiotic therapy, absolute diet with nutritional support and percutaneous drainage of any existing collection. For the specific treatment of the fistula, endoscopic methods are available, such as the placement of endoprosthesis or sealing the fistula with fibrin or clips, all with different results, depending on the experience of endoscopist.

Different intraoperative techniques have been used to decrease the incidence of leaks, but there is no evidence that these methods reliably decrease the leak rate after bariatric surgery [6, 7].

Intestinal Obstruction and Internal Hernia

Internal hernia is a well-documented complication with an incidence rate of 1% to 9% of bariatric procedures performed. It is difficult to diagnose, usually presenting as intermittent and diffuse abdominal pain, which can be resolved spontaneously (spontaneous reduction of the hernia). Occasionally, it may cause vomiting, which forces the patient to attend frequently to the emergency room. In these cases, internal hernia is not always detected in the imaging tests. If progresses to incarceration, intestinal ischemia of the involved segment appears, with risk of strangulation and perforation. When there is a high clinical suspicion of if incarcerated internal hernia, exploring laparoscopy or laparotomy are mandatory [8]. Several types of internal hernia are most frequent: in Roux-en-Y Gastric Bypass, it is the Peterson hernia, located in the space between the alimentary loop and the mesocolon. These hernias can be theoretically prevented by closing this space with non-absorbable suture at the time of surgery. Steele et al., have reported that the antegastric antegrade assembly together with the closure of this space leads to fewer internal hernias than retrogastric and retrocholic assembly [9].

Other causes of early postoperative bowel obstruction are disorders in the jejuno-jejunal anastomosis of Roux-en-Y gastric bypass, that can be caused by angulation, edema of the anastomosis, obstruction by intraluminal clots or extraluminal adhesions. Clinical manifestations are vomits, abdominal distension and pain. Most of these etiologies can resolve with conservative management (nasogastric tube aspiration, fasting and hydroelectrolytic support). However, in some cases surgical treatment is necessary.

Hemorrhage

Significant bleeding after gastric bypass has been described in 0.4% to 4% of patients. The origin of this complication may be intraluminal, appearing as hematemesis, melena or

bright red blood per rectum, or intraperitoneal. It may present with hemodynamic stability or instability. In the first case, a conservative management is usually established, and in the second one a more aggressive treatment is necessary, implying interventional radiology or even an early reintervention to control the bleeding focus. Once confirmed the bleeding, antithrombotic prophylaxis must be discontinued and / or coagulation disorders corrected, in an attempt to control bleeding. The bleeding is most likely as a result of the use large staples in the distal stomach. Large staples are not adequate to seal small vessels. This has led many surgeons to reinforce the staple line by over-sewing, buttressing, or even both [10].

Stenosis

Clinical presentation is similar to an obstruction and includes nausea, vomiting, abdominal pain, and dysphagia. A retrospective review of 230 patients found that the risk of stenosis following a LRYGB, BPDDS, or LSG is approximately 3.3%, 1.2%, and 3.5%, respectively [11]. In the case of Roux-en-Y gastric bypass, the most common site of stenosis is the gastrojejunal anastomosis. The cause of the stenosis is usually multifactorial, but mainly due to technical defect and / or ischemia. The management consists initially in endoscopic dilatation, resolving the stenosis in many patients. Surgery is reserved for the failure of endoscopic treatment [12].

In sleeve gastrectomy, the stenosis is mainly induced by cicatricial retraction. The *incisura angularis* is the most frequent site for the appearance of the stenosis. Nowadays there is consensus that this complication is associated with the caliber of bougie employed for the calibration of the gastric tube. In short- segment stenosis, repeated endoscopic dilatation may be useful. Longer stenoses and those ones not responding to endoscopic techniques, may require surgical resolution [13].

Stomal Obstruction

Acute stomal obstruction is an early complication that can occur in up to 14% of LAGB patients. Obstruction is usually caused by inclusion of excess perigastric fat, use of a narrow band for the thickness of the gastric tissue, or significant tissue edema. Patients usually present with persistent nausea, vomiting, and inability for oral intake. The diagnosis is confirmed with an upper gastrointestinal series, demonstrating no transit of contrast beyond the band. Acute stomal obstruction secondary to edema, can be conservatively treated with nasogastric tube aspiration, though it implies a risk for aspiration pneumonia and gastric ischemia. Persistent obstruction requires surgical revision or removal of the band. Meticulous removal of excess perigastric fat at the time of initial band placement may help to prevent this complication. The use of large diameter bands also reduces the incidence of acute postoperative obstruction [14].

Surgical Site Infection

Surgical site infections (SSIs) often present with the typical signs of cellulitis or perincisional necrosis. Some of them, specially in patients with Diabetes Mellitus, require an aggressive management, including ICU monitoring, IV antibiotic therapy and/or surgical debridement, since they can progress to necrotizing fasciitis with harmful consequences. Actually, with the laparoscopic approach, the incidence and severity of this complication has significantly decreased, though it must be always kept in mind that it may reflect a chronic fistula of intra-abdominal origin. Among laparoscopic techniques, wound infection rates vary depending upon the technique used, with a higher rate of wound infections associated with the use of circular stapling devices to create the gastrojejunostomy [15]. Signs of wound infections include unexplained fever, fluctuance, erythema, or purulent discharge. Treatment consists in opening the wound for drainage of infected fluid, debridement of any devitalized tissue, and antibiotics, when the surrounding skin presents signs of cellulitis [16].

Pulmonary Embolism

It is the second most feared complication in patients undergoing bariatric surgery. Fortunately, its incidence is very low, occurring between 1% and 2% of the cases, although with a mortality rate, that reaches up to 30%. Sometimes the diagnosis may pass undetected (subclinical pulmonary embolism). The most common risk factors associated with fatal PE include severe venous stasis disease, BMI >60, truncal obesity, and obesity-hypoventilation syndrome [17]. The patient presents dyspnea, with signs of sepsis sometimes indistinguishable from those observed in the case of a fistula. Thus, it is crucial to obtain a certain diagnosis. When pulmonary embolism is suspected, a chest CT scan, followed by an abdominal imaging study, is mandatory. Once a fistula is discarded and a pulmonary embolus is confirmed, anticoagulant treatment must be immediately started. When the patient's BMI does not allow the performance of a CT scan, in these cases the management must be aggressive, including exploring laparoscopy and if the intra-abdominal complication is ruled out, anticoagulation must be started. The best way to reduce the possibility of pulmonary thromboembolism is prevention, identifying any risk factors that must be treated preoperatively. Optimal strategies for preventing VTE/PE in bariatric surgery have not been clearly established. Most bariatric surgeons use both pneumatic compression devices and low molecular weight heparin. The current American Society of Bariatric and Metabolic Surgeons (ASMBS) guidelines regarding VTE prophylaxis state that all bariatric patients must receive mechanical prophylaxis and early postoperative deambulation is recommended. Additionally, the surgeon may routinely use pharmacological prophylaxis of either low molecular weight heparin or unfractionated heparin [18].

Pulmonary Complications

Pulmonary complications include pneumonia and acute respiratory failure. Atelectasis is common after all types of surgery that require general anesthesia and orotracheal intubation,

but is more prevalent in morbidly obese patients. The overall incidence of postoperative pneumonia is around 0.4%. The overall rate of acute respiratory failure (ARF) is 1.3%. The incidence is higher with open approach, when compared with laparoscopic one. Incidence is also higher after gastric bypass procedures than after restrictive procedures, and is more prevalent in patients with preoperative heart failure, chronic renal failure, peripheral vascular disease, chronic obstructive pulmonary disease (COPD), tobacco smoking, and diabetes. ARF is associated with a significantly higher in-hospital mortality rate compared with those who do not develop this complication. Early postoperative deambulation and respiratory physiotherapy are important to decrease the incidence of pulmonary complications. Preoperative identification of obstructive sleep apnea and initiation of continuous positive airway pressure (CPAP) therapy also reduces the risk of pulmonary complications in the postoperative course. CPAP should be used in the early postoperative period when it is clinically necessary [19].

Marginal Ulcers

They might appear in the gastrojejunal anastomosis of Roux-en-Y Gastric Bypass, commonly in the jejunal part. The mechanisms of development are not completely understood, but ischemia, tension in the anastomosis and / or *Helicobacter pylori* infection are usually involved [20]. Another important factor is the exposure of this anastomosis to the acid produced in the gastric pouch (when it is excessively large). The incidence of this complication ranges from 0.6% to 16% [21]. The clinical presentation includes pain, loss of appetite, excessive weight loss, nausea, vomiting, anemia and even perforation. As a preventive measure, proton pump inhibitors are used during the postoperative period for 3 months. Of the total number of patients presenting this complication, up to 1/3 would require revision surgery [21]. Risk factors for late presentation of a marginal ulcer include smoking, nonsteroidal antiinflammatory drugs (NSAID), or gastrogastic fistula formation. If NSAIDS are necessary, a concomitant use of a proton pump inhibitor is indicated [22].

Rhabdomyolysis

Rhabdomyolysis is a clinical and biochemical syndrome that includes increase of muscle enzymes, acute renal failure, compartmental syndrome and even death; notwithstanding some cases can be completely asymptomatic. It is produced by the damage and necrosis of the skeletal muscles when exposed to prolonged compression. This compression causes the release of substances (CK) to the plasma, that in excess are nephrotoxic. Its incidence in bariatric surgery is not clearly defined, ranging from 1.4% to 75% [23]. Risk factors identified include prolonged surgical time, extreme surgical positions, ASA III-IV, diabetes or hypertension [24].

Signs and symptoms usually appear during the first 24 hours after surgery. The suspected diagnosis is based on clinical manifestations (reddish-brown urine, gluteal and back pain, oliguria) and must be confirmed in laboratory tests with CK measurement. CK may reach 5-fold higher levels than normal ones [25]. The subsequent development of acute renal failure varies between 20-50%, with a mortality rate of nearly 20%. An early diagnosis of this

complication is essential for a successful outcome. Once the diagnosis of rhabdomyolysis has been made, the treatment consists in intravenous hydration and forcing diuresis with osmotic diuretics, which seems to be the best measures to avoid fatal consequences [25].

LATE COMPLICATIONS

Late complications of bariatric procedures include cholelithiasis, incisional ventral hernia, nutritional deficiencies, neurological and psychiatric disorders.

Cholelithiasis

It occurs in up to 38% of patients within six months after surgery, giving symptoms in up to 41% of these patients. This incidence can be reduced to 2% with a six month course of ursodeoxycholic acid given prophylactically after weight-loss surgery. Cholecystectomy is not routinely indicated during the bariatric surgery, but it is advisable if the patient has symptomatic cholelithiasis preoperatively.

Another related complication is choledocholithiasis following a gastric bypass, with a more complex management. First of all, the diagnosis must be confirmed by ultrasonography or magnetic resonance cholangio-pancreatography (MRCP). Management can be difficult because of the impossibility of direct access to the duodenum. Current therapeutic options include endoscopic retrograde cholangiopancreatography (ERCP) assisted by laparoscopy (with entry into the gastric remnant), transhepatic percutaneous access or surgical approach to the bile duct [26, 27].

Ventral Incisional Hernia

The increase of the laparoscopic approach has raised the overall incidence of port-sites hernias. Considering the difficulty of a correct closure of the incisions added to the obesity status, a correct abdominal wall closure still remains a challenge for the bariatric surgeon [28]. Severe obesity is associated with an increase in intra-abdominal pressure and, therefore, a high risk of developing this type of hernia after a laparotomy. However, its incidence has significantly decreased with the laparoscopic approach (1.8%), when compared with open surgery (24%). To repair the hernia, it is advisable to wait until an adequate weight loss is achieved and post-surgical weight stabilization (more than one year). Early repairs should be considered only in complicated ventral hernias [29].

COMPLICATIONS OF SPECIFIC BARIATRIC PROCEDURES

Roux-en-Y Gastric Bypass

Gastric Remnant Distension

Gastric remnant distension is a rare, but potentially lethal complication with risk of perforation and peritonitis. Symptoms include pain, hiccups, abdominal distension in the left upper quadrant, tachycardia or dyspnea; nausea and vomiting are not frequent. Radiological evidence shows striking gastric remnant distention. The treatment consists in urgent decompression with performance of percutaneous or surgical gastronomy. If the gastrostomy is not feasible or a perforation is suspected, emergency surgery is indicated. Some studies recommend prophylactic gastrostomy in elderly, super-obese patients, patients with diabetic gastropathy and as part of revisional surgeries where gastric emptying might be delayed [30].

Dumping Syndrome

Dumping syndrome can occur in up to 50% of patients who undergo gastric bypass. There are two types of dumping syndrome: early and late [31].

Early dumping syndrome: has a rapid onset, within the first 15 minutes after ingestion and is the result of rapid emptying of food (hyperosmolar and sequestering liquid into the bowel), causing hypotension and reflex response of the sympathetic nervous system. Symptoms include abdominal pain, diarrhea, nausea, and tachycardia. Preventive measures include the suppression of sweet foods and replace them with foods rich in fiber, protein and complex carbohydrates. Usually these symptoms improve in 7 to 12 weeks after surgery.

Late dumping syndrome: is produced by the response of insulin to hyperglycemia, causing hypoglycemia 2 - 3 hours after food intake. Symptoms include dizziness, fatigue, sweating, and weakness. Treatment is similar to that of early dumping syndrome.

Change in Bowel Habits

Diarrhea is more common after malabsorptive procedures and may become uncontrollable in some cases. Constipation may occur in patients with a gastric band and in patients undergoing gastric bypass surgery. They usually improve these changes over time and with medical measures. Treatment with laxatives may be necessary for short periods of time to improve constipation [32].

Failure to Lose Weight and Weight Regain

The lack of weight loss after the Roux-en-Y gastric bypass is rare, and is often due to non-compliance with the postoperative diet. Among the causes of weight regain are eating disorders, development of a gastro-gastric fistula, enlargement of the pouch or dilation of the gastrojejunal anastomosis [33].

Laparoscopic Adjustable Gastric Banding

Early complications of this procedure appear in 1% to 12% of all performed procedures. Hemorrhage is very rare due to the almost lack of dissection of the tissues and there is no

possibility of anastomotic leakage. The iatrogenic perforation of the stomach appears in 0.5% of the cases [34]. The risk of thromboembolic events, such as deep venous thrombosis or pulmonary embolism is 0.1% (lower than in other procedures). Specific complications related to the band may occur days or even years after the procedure. Complications related to the port or tubing of the mechanism can occur in up to 11% of patients [35]. Prolapse of the stomach may be posterior (more common when the band is placed with the perigastric technique) or anterior (*pars flaccida* technique). Clinical manifestations include gastroesophageal reflux disease, oral intolerance, dysphagia and regurgitation. The diagnosis is usually made with an upper GI series. The first thing to do when confirming the diagnosis is to deflate the band, but the definitive treatment is usually surgical repositioning of the stomach and new plication or removal of the band and replacement by a new one, if necessary. When these symptoms appear immediately after increasing the band pressure in the outpatient clinic, the problem will be solved by reducing the volume of the band [36].

Erosion

Patients with this complication may have recurrent port infections, abdominal pain, gastroesophageal reflux, or a feeling of increase or decrease in band restriction after ingestion. The diagnosis is endoscopically achieved and the treatment consists in surgical removal of the band and closure of the gastric perforation. Other treatment option is the endoscopic removal of the band.

Esophageal Dilation

Esophageal dilation might be secondary to a excessively tight band or a prolapsed stomach. The incidence of esophageal dilatation ranges between 5% and 10% upon series [37, 38].

Laparoscopic Sleeve Gastrectomy

Bleeding

Most of the hemorrhages associated with this technique have their origin in the stapling line after the division of the stomach. Other sources of postoperative hemorrhage are short vessels during dissection of the major curvature and inadvertent splenic injury. In order to decrease the bleeding from the stapling line, many surgeons perform a reinforcement with over-sewing, buttressing or both [39].

Stenosis

Stenosis of a sleeve gastrectomy seems like an obstruction. Symptoms include dysphagia, vomiting, reflux, or regurgitation and may even lead to inability of oral intake with dehydration and malnutrition. The most frequent place of stenosis is the gastroesophageal union, followed by the *incisura angularis*. Diagnosis is obtained with upper gastrointestinal series and endoscopy. The most frequent cause of stenosis is the use of a very small bougie. The actual recommendation is to use a bougie of 36 to 40 Fr. We would recommend that the diameter of the bougie must be inversely proportional to the experience of the surgeon with this technique, meaning to use a bougie of greater caliber for the surgeon with less

experience. The treatment of this complication is endoscopic dilation when it is a short stenosis, but for long stenosis, surgery is usually necessary to correct the problem [40].

Gastric Leaks

Gastric leakage is the most feared complication and sometimes difficult to manage. They occur in up to 5.3% of patients. The causes may be tissue ischemia or scars with posterior perforation, generated by the use of hemostatic devices. Some leaks are caused by hyper-pressure generated by distal stenosis. Most of them are located at the gastroesophageal junction, where vascularization is compromised after the section of short gastric vessels; this would generate the ischemia that impels a correct healing of the tissue, leading to the appearance of the leak. Sleeve gastrectomy produces high intragastric pressure, even without stenosis, and this can increase the time necessary for the leak closure [41, 42]. If the patient is clinically stable, a conservative management with drainage of collections, antibiotherapy and total parenteral nutrition can be chosen until resolution of the leak. Other option is the placement of covered stents endoscopically, but it is not always feasible or successful [43].

Reflux

This complication occurs with typical symptoms such as burning pain, heartburn and regurgitation. It may appear early or late in the postoperative period. Initial treatment is with standard drugs used in GERD. If a stenosis is demonstrated, it can be treated by endoscopic dilatation to improve reflux. If the patient does not respond to adequate medical treatment no anatomical cause (stenosis or hiatal hernia) is demonstrated, conversion to a RYGB might be necessary [44].

Malabsortive Procedures

These procedures (Biliopancreatic Diversion and Duodenal Switch) present a higher rate of complications [45]. It is attributed in part to the greater complexity of the surgical technique and that these approaches are usually performed in patients with greater BMI. The marginal ulcer appears in up to 10% of BPD, and 1% to 3% of DS. Dreaded complications are the nutritional deficiencies that appear in the postoperative course, sometimes becoming so severe that they may cause mortality or the need for restitution to the normal anatomy of the gut [46, 47].

ABSTRACT

Bariatric surgery is, so far, the most effective method of sustained weight loss by obese patients. Although different studies have been performed with the aim of understanding the mechanisms by which bariatric surgery elicits weight loss, these are not completely understood. Dietary habits change in patients subjected to different types of bariatric surgery. It is known that bariatric surgery induces weight loss by restricting the amount of food the stomach can hold and/or by reducing nutrient absorption. However, in the recent years, evidence has emerged about variations in sensorial food perception in those patients, which may also be responsible for modifications in food acceptance and preference.

In this chapter, a revision of the studies concerning the effect of bariatric surgery procedures in overall oral food perception will be made, discussing how this may influence choices and dietary behavior. Attention will also been given to the potential effects of bariatric surgery on saliva composition, which may also influence oral perception. For a better framing of the theme, a review of the main endocrine-metabolic aspects of each type of bariatric surgery procedure, as well as physiology of taste and olfaction, will be made.

1. INTRODUCTION

Bariatric surgery is considered safe and the most effective method for sustained weight loss in treating morbid obesity. The different types of bariatric surgery are based in two main concepts: restriction and malabsorption. Restrictive procedures aim to regulate the amount of calories consumed by decreasing the gastric area capable of receiving food. The malabsorptive type reduces the area of intestine in contact with food, decreasing the absorption of nutrients and consequently energy (Elder and Wolfe, 2007). Some types of bariatric surgery procedures combine these two concepts. Independently of the type of surgery, the patient's understanding, motivation, and participation are key factors for the success of the intervention. To consider bariatric surgery as a restrictive and/or malabsorptive procedure is an oversimplification, and there is increasing evidence that factors such as neural and endocrine signaling pathways affecting appetite and satiety, including those affecting sensorial aspects and reward of food intake, are all operative to a variable extent in inducing weight loss (Wolfe et al., 2016).

The different types of bariatric surgery are Roux-en-Y gastric bypass (RYGB), sleeve gastrectomy, biliopancreatic diversion with duodenal switch and implantation of devices. In the latter case, the most common devices are adjustable gastric banding (which constricts the size of the gastric pouch and outlet), intermittent vagal blockade (where leads are placed around the vagal trunks at the diaphragm to produce an intermittent vagal blockade and an increase in satiety), and gastric balloons (which fill the stomach, leaving less space for food) (Buchwald, 2005; Elder and Wolfe, 2007; Ionut et al., 2013).

The effects of bariatric surgery comprise not only the direct effect on gastrointestinal capacity to receive, digest, and absorb foods, but also effects at the level of the complex interaction between signals from the gastrointestinal system, adipocytes, the central nervous system and hormones. Changes in post-ingestive responses occur (Quercia et al., 2014), which will be further presented in this chapter. Moreover, there is evidence that individuals submitted to bariatric surgery change their hedonic drive to consume palatable food, what appears to be also related to changes in the way in which they perceive food sensorial signs, namely taste (Pepino et al., 2014) and odors (Jurowich et al., 2014). Changes in food choices, with the establishment of healthier dietary habits, have been observed, such as an increased intake of protein-rich foods and vegetables and a reduced consumption of sugar and fat contained snacks (Ullrich et al., 2013).

The effect of bariatric surgery in oral food perception may include an effect on the constituents of oral medium responsible for taste and aroma perception. In this context, knowledge about changes in saliva composition may help us in understanding oral food perception changes. Based on this assumption, this chapter presents the main functions of this fluid, as well as factors affecting its composition and its relationship with oral food perception and ingestion. Although it has not yet much explored, our group has evidence that saliva composition changes in obesity (Lamy et al., 2015; Rodrigues et al., 2015) and that some of those changes appear to be reverted in individuals subjected to bariatric surgery (Lamy et al., 2015). Those studies will be reviewed and discussed in the context of possible influences of bariatric procedures in food perception.

2. BARIATRIC SURGERY

2.1. Bariatric Surgery, Weight Loss, and Eating Behavior

The main objective of bariatric surgery is weight loss, with the consequent treatment of the comorbidities associated with obesity and derived from excess body weight and adiposity.

As a weight loss procedure, the benefits of bariatric surgery are greater than those of lifestyle intervention and pharmaceutical management. It has the additional benefits of reducing risk factors for and leading to remission of comorbid conditions. Furthermore, the initial cost of bariatric surgery can be recovered within two years through reduced patient reliance on medication, fewer physician visits, increased employment, and increased productivity in the workplace.

There are a number of surgical procedures currently available to promote weight loss, together called bariatric surgery (reviewed in Buchwald, 2005; Elder and Wolfe, 2007; Ionut et al., 2013). In 2004, the consensus congress of the American Society for Metabolic and Bariatric Surgery concluded that: *'Bariatric surgery is the most effective therapy available for morbid obesity and can result in improvement or complete resolution of obesity comorbidities'* (Buchwald, 2005). In general, bariatric surgery reduces caloric intake by restricting the size of the stomach, limiting the absorption of nutrients in the intestine, or combining restrictive and malabsorptive components.

Different authors cite different percentages of weight loss after surgery, with some of them finding similar results for the various types of bariatric surgery and others reporting differences. The velocity of weight loss is also not consistent across different studies. Even so, there is generally rapid weight loss over the first six months, with maintenance, but at lower rate, of weight loss over time. After RYGB, 12% to 45% total decrease in body weight was reported three years after surgery (LABS, 2009). For the laparoscopic adjustable gastric band, a total body weight loss of 15.9%, at three years post-surgery was reported (Sjöström et al., 1999), whereas for gastric balloon most of the decrease in weight occurs during the initial months post-surgery, with reports of losses higher than 10% initial body weight after one year (Dogan et al., 2013).

Besides the changes in terms of the amount of food that an individual is able to eat and in nutrient absorption, weight loss requires the adoption of eating habits different from those practiced before surgery. General recommendations include the ingestion of very small, frequent and nutrient-dense meals and the avoidance of foods high in fat and/or sugar.

Alterations in dietary patterns appear to be one of the most documented effects of all bariatric surgical procedures. With the RYGB procedure, decreases in the consumption of the majority of sugar-containing foods and beverages, as well as in fatty foods, are reported (Molin Netto et al., 2017). For sleeve gastrectomy, improvements in healthy dietary habits were reported, namely with a short time between food intake and reduced appetite (Bužga et al., 2014). Using rats as an animal model, a decrease in the intake of dietary fat and a shift preference towards lower calorie-dense foods was observed after vertical sleeve gastrectomy (Wilson-Perez et al., 2013).

Bariatric surgery results in a decreased capacity to hold high amounts of food in one meal. However, some patients replace the high amounts of food in one meal by a frequent snacking of caloric food. It was shown that when this occurs, less weight is lost, or weight

regain may even occur (Leite Faria et al., 2009). Some authors also observed a greater preference for lower-calorie over higher-calorie after RYGB (le Roux and Bueter, 2014). Some authors observed that the decrease in the proportion of daily calorie intake from sweetened foods and beverages is higher after RYGB than after laparoscopic adjustable gastric banding surgery (Pepino et al., 2014).

It is also known that several extremely obese patients develop food addiction and that such food addiction may influence the efficacy of bariatric surgery in terms of weight loss. Nevertheless, it seems that bariatric surgery-induced weight loss may also help to treat food addiction, improving eating behavior in these patients (Pepino et al., 2014).

The main factors identified as responsible for dietary changes after bariatric surgery are: food intolerances, prevention of dumping syndrome symptoms, optimization of weight reduction, alteration of neuroendocrine regulation, and nutritional counselling and education about healthy choices (Molin Netto et al., 2017). The subsequent points will discuss aspects related to post-ingestive consequences and oral food perception, which may help to improve dietary habits.

2.2. Hormonal/Post-Ingestive Changes Induced by Bariatric Surgery

Bariatric surgery is coupled with changes in gut/gastro-intestinal hormones, which may also result in diverse changes in appetite/satiety control. This appears to be a reason for the sustained weight loss achieved with these procedures (Ionut et al., 2013). Complications such as hyperinsulinemia, resistance to insulin and diabetes type II are significantly attenuated after bariatric surgery, even before an amount of decrease in fat mass that could explain that. The mechanisms responsible for that are not completely understood, but gut hormones and peptides involved in the regulation of appetite/satiety have been implicated (Ionut et al., 2013).

The regulation of appetite/satiety, together with energy expenditure, is a complex process, involving central and peripheral signals (Coll et al., 2007; Perry and Wang, 2012). In the long-term regulation of satiety, two anorexigenic hormones – leptin and insulin – are the main intervenient, signaling the levels of energy stores (Perry and Wang, 2012; Rui, 2013). For short- to medium-term regulation, although the aforementioned hormones continue to play a role, gastrointestinal peptides/hormones are primarily responsible, acting both at nervous and circulatory level (Perry and Wang, 2012; Rui, 2013).

Ghrelin is produced by the endocrine cells of the gastric fundus and acts on the hypothalamic arcuate nucleus, promoting appetite and thus weight gain and stimulating growth hormone release (Kojima et al., 1999). During weight loss induced by diet, plasmatic levels of ghrelin are increased (Cummings et al., 2002). However, in the process of weight loss induced by surgery this is not necessarily true. The reduction of considerable stomach volume, as occurs in laparoscopic sleeve gastrectomy, results in significant reduction in ghrelin levels (Sista et al., 2016). In this case, the majority of the cells from the gastric fundus, which produce ghrelin, are removed. For Roux-en-Y gastric bypass the existing data present no consensus, with studies showing decreases in terms of both fasting and postprandial conditions after this type of surgery (Cummings et al., 2002; Geloneze et al., 2003), whereas others, by contrast, report increased levels of ghrelin (Kalinowski et al., 2017). For laparoscopic gastric banding, different studies also present different results, with

observation of: 1) slight or no differences in ghrelin levels (Hanusch-Enserer et al., 2003); 2) increased plasmatic ghrelin concentrations (Uzzan et al., 2007). The mechanisms involved in the release of ghrelin after bariatric surgery are not completely understood and the levels of insulin and insulin resistance before surgery may affect ghrelin release following surgical weight loss (McLaughlin et al., 2004).

Gastrin is a family of multiple peptides produced in the gastric antrum and duodenum by the enteroendocrine G cells. Their production responds to food ingestion, with increases in the secretion of acid and increases in satiety (Meek et al., 2016). Bariatric surgery involving decreased access of food to G cells appears to reduce gastrin levels, such as been observed in Roux-en-Y surgery (Sundbom et al., 2007). In other surgical practices, where G cells maintain contact with food, such as gastric banding, no changes in fasting gastrin concentration were observed (Shak et al., 2008).

At the level of intestine peptides such as cholecystokinin (CCK), gastric inhibitory peptide (GIP), glucagon-like peptide-1 (GLP-1), oxyntomodulin, and Peptide YY (PYY) are produced and contribute to regulating food intake (Meek et al., 2016). CCK is secreted in the duodenum by I cells, mainly in response to the presence of amino acids and fatty acids in the duodenum. CCK promotes bile secretion into the gut lumen, the release of digestive enzymes from the exocrine pancreas and a decrease in the rate of gastric emptying (Meek et al., 2016). As well as for the other gastrointestinal peptides/hormones, results from different studies and different types of bariatric surgery do not present the same results. A decrease was observed in CCK levels after the non-surgical bariatric technique duodenal-jejunal bypass linear, which mimics the exclusion of the proximal small intestine that occurs in Roux en-Y gastric bypass (de Jonge et al., 2016). However, other studies have shown increases in CCK levels after Roux-en-Y gastric bypass (Jacobsen et al., 2012). Sleeve gastrectomy was reported to result in increases in levels of CCK (Peterli et al., 2012). For gastric balloon surgery, there are reports of stimulation of CCK release (Feinle et al., 2002) and reports of reduced levels of this peptide after surgery (Mathus-Vliegen and de Groot, 2013).

Gastric inhibitory peptide (GIP), also known as glucose-dependent insulintropic peptide, is another intestinal peptide produced by K cells, the majority of which are located in the duodenum and proximal jejunum, with smaller numbers also occurring throughout the entire small intestine (Baggio and Drucker, 2007). GIP is secreted in response to nutrient ingestion, especially glucose or fat (Baggio and Drucker, 2007), and it has an incretin effect, i.e., it induces insulin secretion in response to glucose in the duodenum. Bariatric procedures that reduce the contact of nutrients with parts of the intestine have been reported to result in a reduction in GIP secretion (Guidone et al., 2006), although this has been not observed in all studies (Laferrère et al., 2008). After biliopancreatic diversion, decreasing levels of GIP were also observed (Sarson et al., 1981), whereas after gastric banding, no change in fasting GIP concentrations were reported 6–12 months after surgery (Shak et al., 2008).

Similarly to GIP, GLP-1 has an incretin effect and is also secreted a few minutes after ingestion, augmenting insulin response and decreasing glucagon secretion. This peptide, secreted by intestinal endocrine L cells, induces satiety, while sustained GLP-1-receptor activation is associated with weight loss (Baggio and Drucker, 2007). An increase in postprandial GLP-1 response was observed after Roux-en-Y, not only after some time (le Roux et al., 2007), but also before weight loss (Laferrère et al., 2008). Nonetheless, laparoscopic adjustable gastric banding was not observed to induce an enhanced GLP-1 response (le Roux et al., 2007).

Peptide YY (PYY) belongs to the pancreatic peptide family and, similarly to GLP-1, is released postprandially by intestinal endocrine L-cells proportionally to the amount of calories ingested. The secretion of PYY induces satiety and reduces food intake. Malabsorptive bariatric surgery types, such as Roux-en-Y, appear to cause an increase in the stimulation of L-cells, increasing the postprandial response of PYY (Korner et al., 2005; le Roux et al., 2007). The same was not observed for restrictive types of bariatric surgery, such as adjustable gastric banding (le Roux et al., 2007).

Another intestinal peptide involved in the regulation of food intake that may be affected after bariatric surgery is oxyntomodulin, which is a peptide belonging to the enteroglucagon family of peptides and arises from post-translational processing of proglucagon in intestinal cells. The release of oxyntomodulin into blood responds to food ingestion, being proportional to the caloric content of the meal (Cohen et al., 2003). Jejunio-ileal bypass surgery results in a marked elevation of oxyntomodulin levels (Sarson et al., 1981). The exaggerated increase in the levels of this peptide in Roux-en-Y surgery has been linked to the dumping syndrome, which is a side-effect greatly associated with this type of bariatric surgery (Meek et al., 2016).

During the previous description of the changes in gastrointestinal peptides/hormones paired with bariatric surgery, one of the hormonal modifications that were cited as a consequence of the altered secretion of these peptides is insulin secretion and sensitivity. As we started by stating, one of the metabolic complications derived from obesity that has considerable improvements with bariatric surgery is diabetes type II. These benefits in glucose metabolism are particularly evident and occur early in types of bariatric surgery that bypass contact with the proximal parts of intestine, such as Roux-en-Y (le Roux et al., 2007). On the other hand, when food makes contact with the stomach, as in adjustable gastric banding, improvements in insulin sensitivity and glucose metabolism emerge later, mainly paired with body weight reduction (Usinger et al., 2011). Changes in insulin levels and sensitivity may also affect appetite/satiety after bariatric surgery, as insulin participates in the regulation of food intake by acting at the level of hypothalamus, inducing satiety (Vetter et al., 2009).

3. ORAL FOOD PERCEPTION

3.1. Mechanisms Involved in Flavor Perception

The flavor of food, often confused with taste or aroma, is defined as the combination of tastes, smells, and trigeminal and tactile sensations, as well as the visual and auditory cues that we perceive when tasting food (Spence, 2015a). During ingestion, the flavor of the food is integrated with post-ingestive cues, influencing palatability and acceptance. This association of the post-ingestive signals with oral food perception is the basis for unconditioned stimulation, which is responsible for the acceptance of some naturally aversive stimuli, such as bitter and astringent ones, or for the rejection of some flavors that were pleasurable before a gastric disease (Beauchamp and Mennella, 2009).

Taste results from chemical stimulation at the level of taste receptor cells located on taste tissue in the tongue, palate and epiglottis. Smell respects the detection of volatile compounds in the upper region of the nose. Moreover, volatiles that are released during mastication in the

mouth can be detected through retronasal route, making what is defined as a food aroma. Concerning chemosensory stimulation, this occurs through activation of receptors in the mucosa in the mouth and nose.

It is important to note that oral food perception (at the level of taste, smell or aroma) involves different psychological components: sensory-discriminative and hedonic. The sensory-discriminative component relates to the capacity to detect and differentiate different qualities of stimulants, or the intensity with which these stimuli are perceived. On the other hand, the hedonic component relates to the satisfaction with that stimuli, i.e., how much they are liked or disliked (Spence, 2015a).

It is known that the hedonic component of oral food perception may be affected by different factors, but one of the factors already reported is the amount of sensory experience with a particular stimulus. It was observed that decreasing the habitual consumption (habitual contact) of food with particular sensorial characteristics may reduce preferences for those characteristics (Bertino et al., 1982).

3.2. Basics of Taste Anatomy and Physiology

A comprehensive description of the gustatory system is beyond the scope of this chapter and has been reviewed by different authors (e.g., Hadley et al., 2004; Breslin and Huang, 2006; Hornung, 2006). We will only introduce basic concepts that will be discussed later on.

In terms of taste anatomy, taste cells are organized in groups, with an onion shape, called taste buds. Each taste bud consists of approximately 100 taste cells belonging to four types: i) type I, with glia-like functions; ii) type II, considered to be taste cells, harboring the protein receptors for the basic tastes; iii) type III, which expresses the constituents of the synaptic vesicle machinery; iv) considered basal cells, believed to be stem cells that may replace mature cell types (Witt and Reutter, 2015).

At the moment, five types of basic tastes are unanimously considered: sweet, salty, bitter, sour, and umami or savory. A growing number of researchers now believe that metallic and fatty acid tastes deserve to be added to the list, while others have argued that there may be as many as 25 different basic tastes; however, these remain controversial (Spence, 2015a). Tordoff and colleagues (Tordoff et al., 2012) provided the first evidence for calcium taste transduction in the human oral cavity. However, some authors maintain that calcium signaling is a complex dynamic process in taste cells and in this context it is difficult to consider it as a taste quality (Medler, 2015). Research about the possible existence of the taste of fat and its regulation gained interest mainly due to the potential connection that this may have with the acceptance of or preference for fatty foods, which is particularly important in the context of obesity and public health. Fat taste has been proposed based on the observation that fatty acid receptors are present in the oral cavity, at taste bud level, specifically in the circumvallate and foliate papillae (Simons et al., 2011). One of the main concerns in defining fat as a taste is the fact that there is no obvious perceptual independence from other taste qualities, as some researchers claim that there is no well-defined perception of fatty acids (Galindo et al., 2012). Despite the lack of conclusion about fat as a taste, the oral perception of fatty acids has been demonstrated to be able to predict dietary behaviors related to fat consumption, both in human and animal models, suggesting a functional significance of oral fat perception (Keast and Costanzo, 2015).

Sweet, bitter, and umami taste transduction occurs through protein membrane receptors (Roper, 2007) attached to gustducin, a G protein composed of the products of the GNAT3 (α -subunit), GNB1 (β -subunit) and GNG13 (γ -subunit). The binding of tastant to membrane protein receptor results in an intracellular cascade that culminates in membrane depolarization and the release of signal to nerves that convey information to taste centers in the Central Nervous System (CNS) (Roper, 2007). Salty taste may be transduced by epithelial Na channels similar to those found in renal tissues, while sour transduction appears to be initiated by intracellular acidification acting on acid-sensitive membrane proteins (Roper, 2007).

Despite taste receptors having initially been identified in the oral cavity (mainly on the tongue), over recent years several studies have emerged referring to the presence of taste receptors in the organs of the gastrointestinal system and in other extra-gustatory tissues (Wu et al., 2002; Iwatsuki et al., 2012; Depoortere, 2014; Laffitte et al., 2014). Nutrient sensing at gut level appears to be important not only for digestion, but also for controlling food intake. TAS1Rs, which comprise sweet and umami taste receptors, have been detected in different endocrine cells from the intestine and X/A-like cells from the stomach, and their activation by nutrients results in gut hormone secretion, what may serve to regulate food intake (Janssen and Depoortere, 2013). Some studies have shown that the family of human bitter taste receptors (TAS2Rs) are not only expressed in mucous epithelial cells of the tongue, but also in epithelial cells of the stomach, small intestine, and colon (Rozengurt and Sternini, 2007; Behrens and Meyerhof, 2011; Prandi et al., 2013). These receptors are activated by molecules similar to the ones that activate them in oral cavity (e.g., quinine, denatonium benzoate). Intragastric infusion of denatonium benzoate in rodents produced flavor aversions, preventing future ingestion of other bitter compounds (Glendinning et al., 2008), raising the possibility that agonists of TAS2Rs might be useful in obesity, as they would potentially prolong satiety (Calvo and Egan, 2015).

3.2.1. Influences of Hormones and Gastrointestinal Peptides in the Taste System

In recent years the direct influence of hormones and peptides involved in the regulation of food intake and in taste perception has been suggested. CCK acts at the level of cholecystokinin receptor A, in taste cells, in an autocrine fashion. Its action appears to increase bitter signaling (Herness and Zhao, 2009) and to decrease sweetness (Hajnal et al., 2005). The peptide YY, which induces satiety after food ingestion, is produced at the level of both the intestine and cells in taste buds. Moreover, receptors for this peptide exist in taste cells (Hurtado et al., 2012) and, in mice, it was observed that a lack of PYY results in reduced preferences for fat oral perception (La Sala et al., 2013). GLP-1 and its receptors have been reported to be present in TAS1R-expressing cells (Martin et al., 2009), i.e., in cells expressing receptors for sweet and/or umami tastes. The functional action of this gastrointestinal peptide in sweet taste response has been reinforced by the observation that mice deficient in GLP-1 receptor have a decreased perception of sweeteners, either containing calories or artificial ones (e.g., sucralose), and an increased sensitivity to umami (Martin et al., 2009). Receptors for ghrelin, a gastric hormone that induces appetite, have been reported to be present in taste buds (Shin et al., 2010). It seems that ghrelin may decrease response to salty and sour tastes (Kang et al., 2011), as well as to the stimuli evoked by long-chain fatty acids (Shin et al., 2010).

The hormone leptin is greatly involved in the long-term regulation of energy balance, reflecting the adiposity levels of individuals. The studies about the role of this hormone in the

regulation of taste perception, gained interest, particularly in the case of sweet taste. A relation between plasma leptin levels and sweet taste has been proposed by different authors based on studies performed both in humans (Sanematsu et al., 2009) and rodents (Shigemura et al., 2004). However, studies are not totally in agreement: whereas some reported decreased responses to the sweet stimulus sucrose (Kawai et al., 2000; Yoshida et al., 2013), others reported an increased responsiveness (Lu et al., 2012), or no observable effects on sweet taste response (Glendinning et al., 2015). Sweet has been the basic taste most linked to leptin effects, with some authors arguing that this hormone does not influence the responses for the other basic tastes (Yoshida et al., 2015). However other studies observed that men of a regular weight who are sensitive to the bitter taste elicited by PTC (phenylthiocarbamide) or PROP (6-n-propylthiouracil) presented higher plasma (Wang et al., 2014) or saliva (Rodrigues et al., not published) leptin levels in comparison to their non-sensitive counterparts.

3.3. Basics of Aroma Perception

It is clear that olfaction is an important external signal used by humans to assess the palatability of foods and select foods in general. It has been suggested that as much as 75%–95% of the taste of food (i.e., as transduced by the gustatory receptors on the tongue) results from the stimulation of the olfactory receptors in the nose instead (Spence, 2015b). It has been argued that with a greater amount of the brain devoted to olfaction, humans may in many ways equal other animals in their olfactory abilities. It is important to distinguish between orthonasal smell when we sniff (which tells us about the aroma of food) and the retronasal smell when air is pulsed out from the back of the nose as we swallow. It is the retronasal aromas that are combined with gustatory cues to give rise to flavors (Spence, 2015b).

Olfactory receptors located on olfactory cilia bind odorants that have been dissolved in mucus in the olfactory region of the nose. Each receptor cell apparently expresses a single receptor, which recognizes a small number of odorants. Our olfactory sense plays an important role in eating behavior by modulating our food preferences and intake, while hunger or satiety may also influence how we perceive odors (Plailly et al., 2011; Tresserra-Rimbau et al., 2013).

Volatile molecules from foods are not only detected through the nose, but also via the retronasal route. Aroma release and perception is a complex process that is perceived in the oral cavity, during mastication of food, by the release of volatiles. During chewing the velum-tongue opens (le Roux and Bueter, 2014), allowing the passage of volatiles (aroma compounds) from the mouth to the nose, reaching receptor cells (Hannig et al., 2016). Aroma release and perception are affected by different factors, and the exact influence of each of these factors is not completely understood. A negative correlation between mastication and volatile release was reported in a study performed with flavored candies (Blissett et al., 2006). With flavored model cheese, Pionnier and colleagues observed a positive correlation between respiratory rate, chewing activity and aroma release (Pionnier et al., 2004). This effect of chewing activity has been supported more recently, in a study where different factors with potential effect in aroma release were tested and where masticatory behavior was observed as being the major factor (Feron et al., 2014).

Aroma perception depends not only on volatile release, but also on detection at receptor level. Factors that may influence this detection will influence perception. Adaptation appears to influence aroma perception: if the receptors were subjected to a constant level of stimulation by a particular volatile, then the response to that volatile would decrease with time (Baek et al., 1999).

Despite a lack of studies about the potential effect of hormones or gastrointestinal peptides in aroma perception, several studies report changes in olfactory function induced by hormones. For example, orexin was reported to increase olfactory sensitivity, whereas leptin reduces that sensitivity (Valladares Vega and Obregon Rivas, 2015).

Olfaction is modulated in response to changing levels of various molecules, such as ghrelin, orexins, neuropeptide Y, insulin, leptin, and cholecystokinin (Palouzier-Paulignan et al., 2012). The current known distribution of peripherally and centrally derived energy-signaling molecules and their receptors in the olfactory system are reviewed by Palouzier-Paulignan and colleagues (Palouzier-Paulignan et al., 2012).

3.4. Changes in Oral Food Perception after Bariatric Surgery

3.4.1. Changes in Taste Function

Changes in food preferences and dietary habits are associated to weight loss, both with or without bariatric surgery. Studies about changes in preferences after diet-induced weight loss reported increases in preferences for sweet, starchy, and high-fat foods. However, these were different for individuals who maintained a low-fat diet in comparison with those who maintained a low-carbohydrate diet (Martin et al., 2011). Others studies reported a decline in dietary preference for fat following a low-fat diet over six months (Ledikwe et al., 2007). However, these studies do not elucidate whether changes in preferences are influenced by stimuli perception at taste receptor level.

As in diet-induced weight loss, patients after bariatric surgery typically report changes in palatability of sweet and high-fat foods. Different studies have reported altered taste perception in bariatric surgery patients, which appears to depend on the type of bariatric procedure used. Different evidences emerge from different studies, which can be sometimes be related to the type of surgery and/or to the type of methodologies used to access taste – i.e., some studies evaluate taste perception through the evaluation of taste sensitivity, whereas others evaluate it through the perceived intensity, and others through preferences. By employing the forced choice three stimuli drop technique, Scruggs and colleagues (Scruggs et al., 1994) studied the effects of gastric bypass surgery in taste detection and observed a decrease in the detection thresholds for the basic tastes of sweet, bitter, salty, and sour, which means higher sensitivity for these four taste qualities. However, other authors reported decreased taste thresholds only for the sweet taste, but not for bitter (Burge et al., 1995). In terms of preferences, increased affinity for a salty taste was reported for bypass patients, whereas gastric banding patients had increased affinity for a sweet taste (Tichansky et al., 2006). Statistically significant improvements in the acuity for the different basic tastes (sweet, sour, salty, and bitter) were reported for obese patients after sleeve gastrectomy (Altun et al., 2016).

In one of the most recent and comprehensive studies, modifications in eating behavior was observed to be similar following Roux-en-Y or laparoscopic adjustable gastric banding (Pepino et al., 2014). However, when subjects were matched on the amount of weight lost, the contribution of the taste system towards those changes appears to differ. Whereas in Roux-en-Y surgery the hedonic value of sweet was significantly affected, in laparoscopic adjustable gastric banding this was not so evident: patients from Roux-en-Y surgery find the sweet taste less pleasurable than before (Pepino et al., 2014). However, the authors did not observe changes in taste sensitivity, suggesting that alterations in preferences could be not directly related to events at taste receptor level (Pepino et al., 2014).

3.4.2. Changes in Aroma/Odor Perception

Alterations in smell after bariatric surgery have been observed, but few data are available.

Richardson and colleagues (Richardson et al., 2012) observed that absolute olfactory dysfunction present in morbidly obese persons is not affected by weight loss, and data from other authors suggest that a substantial body weight loss per se does not affect olfactory perception. Their results point to the improvement of olfactory perception after sleeve gastrectomy but not Roux-en-Y gastric bypass (Jurowich et al., 2014). In a cohort of patients undergoing Roux-en-Y gastric bypass, it was reported that subjective changes in appetite, taste and smell are very common after this surgery (Graham et al., 2014).

Enck and colleagues (Enck et al., 2014) observed that bariatric surgery did not change odor sensitivity, but some morbidly obese patients exhibited abnormally low olfactory functions prior to and after surgery, concluding that olfactory functions in normal healthy volunteers and obese patients suffer only marginal effects with the manipulation of the hunger/satiety state.

Holinski and colleagues (Holinski et al., 2015) prospectively analyzed the orthonasal olfactory function and the gustatory function with psychophysical testing in highly obese adult patients undergoing laparoscopic bariatric surgery. In this study, about 25% of the morbidly obese patients were treated with hypnosis, with a significant decrease in discrimination and identification capacity. Six months after laparoscopic bariatric surgery, the olfactory function ability to discriminate was improved, and about 25% of morbidly obese individuals had limited gustatory function.

In another study the majority of patients presented taste and olfactory changes soon after surgery, independently of type of procedure (Zerrweck et al., 2016). Patients submitted to laparoscopic gastric bypass more often identified a different smell in food, and a higher percentage of excess weight loss was observed in individuals presenting any food aversion, especially in the laparoscopic gastric bypass group as compared with individuals submitted to laparoscopic sleeve gastrectomy.

Further studies are needed to understand if these changes are real, along with determining the durability of changes, and understanding the underlying mechanisms, influence of gender, obesity comorbidities, percentage of weight loss, and whether they are related to the surgical procedures/techniques adopted (Makaronidis et al., 2016).

4. SALIVA: AN IMPORTANT FLUID IN ORAL FOOD PERCEPTION

4.1. Saliva Secretion, Composition, and Functions

Whole saliva is the secretion product of three pairs of major salivary glands (parotid, submandibular, and sublingual), numerous minor salivary glands (e.g., lingual, labial), and gingival crevicular fluid (Pedersen et al., 2002). This fluid, consisting of approximately 99% water, contains a wide variety of constituents, of organic and inorganic origin, as well as cells and microorganisms.

The three pairs of major salivary glands – parotid, submandibular, and sublingual – produce different secretions and have different contributions according to the type of stimulation. Parotid glands, located on each side of the face, under the ears, are serous in nature and produce a watery saliva, with little or no mucins. These glands have a higher contribution for total saliva following stimulation by mastication. Parotid secretion contains different constituents, including different salivary proteins, which include digestive enzymes such as amylase. Sublingual glands, located under the tongue, are mucous glands, with a secretion rich in mucins. Submandibular glands, which contribute to a high proportion of secretion for the total of saliva when resting, are mixed glands, with the resultant product having characteristics between parotid and sublingual secretion (reviewed in Proctor, 2016).

The inorganic part of human saliva comprises about 0.2–0.4% of the fluid. Ions such as Na^+ , K^+ , Mg^{2+} , Ca^{2+} , Cl^- , HCO_3^- , and HPO_4^{2-} are found in variable proportion in saliva. Bicarbonate (HCO_3^-) and phosphate (PO_4^{3-}) ions have considerable buffering capacity and, together with proteins, participate in the regulation of salivary pH. When resting, saliva has a pH ranging between 5.75 and 7.05, increasing with stimulation of salivation to 8.0 (Singh Mamta et al., 2013). Saliva ionic composition is different in resting vs stimulated conditions. Whereas in non-stimulated conditions, saliva is slightly hypotonic, relative to plasma, when stimulated its composition is closer to that of plasma (Pedersen et al., 2002).

Proteins and peptides comprise an important part of the organic composition of saliva. Salivary proteins have diverse functions, namely protection for teeth and oral tissues, taste perception, and participation in ingestive and digestive processes (Humphrey and Williamson, 2001).

Considerable research has confirmed saliva to be one of the most important factors influencing oral health. Organic and inorganic constituents of saliva contribute to the protection of oral structures. Salivary glucose levels have been associated with poor oral health in diabetes mellitus patients. A positive correlation between salivary glucose levels and oral *Candida* carriage has been observed (Naik et al., 2014), which can result in acid production, with the resultant decrease in salivary pH (Darwazeh et al., 1991).

4.2. Relation between Saliva Composition and Food Intake: Potential Effect of Changes to Dietary Regimens

Saliva composition is dynamic in nature and is influenced by different factors, one of which is food intake. Physical and chemical stimulation, such as mastication and taste stimuli, strongly affect salivary gland functionality, with modifications in saliva constituents (Dawes

et al., 2000). Stimulation with different tastants has been observed to result in short-term variations in the levels of different salivary proteins (Neyraud et al., 2006). This salivary response appears to occur not only for oral stimulation with basic tastes, but also for other oral sensations, such as pungency and burning (Lorenz et al., 2011). In terms of masticatory activity, a positive relationship with the contribution of parotid glands has been observed, whereas submandibular glands are primarily responsible for unstimulated (resting) saliva. Long-term changes in masticatory activity also induce changes in salivary function and the resultant composition of secretion product (Pedersen et al. 2002).

The composition of diet is also a factor responsible for variations in type and amounts of saliva constituents. For example, in animals, it is well recognized that species with different dietary chemical composition present dissimilarities in their saliva composition (for a review, see Baptista et al., 2010). One of the most studied cases is the induction of salivary proline-rich proteins with the increased consumption of tannins (e.g., Lamy et al., 2008; Lamy et al., 2011). In humans, the exposure to polyphenolic compounds present in food and drink also seems to change salivary secretion and composition. Short-term exposure to tannic acid resulted in changes in salivary protein profile, which appeared to be different in individuals with high sensitivity to astringency, in comparison to those with low sensitivity for such sensation (Dinnella et al., 2010). Salivary amylase, PRPs, and cystatins have been proposed as salivary proteins and change in expression levels after stimulation with tannic acid solution (Dinnella et al., 2010).

For the same individual, changes in diet composition induce changes in saliva secretion and in the type and amount of compounds present in this fluid. A change from a standard diet to a high-fat diet over a long period results in changes in saliva protein composition, as was observed in a rat model (Rodrigues et al., 2015). This study did not test whether this was a direct result of the presence of higher amounts fat in the diet or an indirect result due to changes in the proportion of the other macro- and micronutrients, or even an indirect result of metabolic alterations in the animal. Nevertheless, in general, the study indicated the potential effects of changes in diet on saliva composition. A significant correlation between dietary and salivary fatty acid composition had already been observed before (Actis et al., 2005), showing that dietary fat may also change salivary constituents other than proteins.

The effect of changes in dietary patterns on saliva composition was studied by comparing an omnivore regimen with lactovegetarian and vegan regimens. A long-time change to a lactovegetarian diet was observed to induce changes in saliva secretion rate, buffer capacity and sodium concentration (Johansson and Birkhed, 1994). The observation of higher saliva secretion rates in vegetarian individuals in comparison with meat-eaters was hypothesized to be due to the slightly alkaline pH of most vegetable-driven foods (Amirmozafari et al., 2013). Concomitantly with changes in flow rate, decreases in peroxidase, catalase, and superoxide dismutase activities were also reported in saliva from vegetarian individuals (Amirmozafari et al., 2013).

It is not only the case that diet affects saliva secretion, as saliva secretion may affect dietary choices and nutritional status. A recent study observed that individuals with hyposalivation have, on average, nutritionally poorer alimentary habits, with a lower intake of vegetables and fish, polyunsaturated fatty acids, potassium, and vitamins D, E, and B6 (Iwasaki et al. 2016).

4.3. Saliva Changes Induced by Lifestyle Factors

Lifestyle factors, including exercise, are relevant in the context of obesity. Independent of diet, although possibly related to it, are lifestyle factors affecting oral medium characteristics, namely smoking, alcohol consumption, and physical exercise. The detrimental effect of chronic alcohol drinking on salivary proteins with defense functions is known. For example, chronic alcohol consumption decreases the levels of lactoferrin, peroxidase, immunoglobulin A and lysozyme (Waszkiewicz et al., 2012 a, b, c). A lesser level of glycosylation of salivary proteins from alcohol-dependent individuals was also cited, and suggested as a possible cause of an increased susceptibility to oral pathologies (Kratz et al. 2014). Physical exercise is known to produce alterations in salivary flow and protein composition. The higher viscosity of saliva produced during exercise is not a new discovery (Dawes, 1981). Despite such increase in viscosity having been primarily attributed to systemic dehydration after intense exercise, together with increased mouth breathing, which in turn reduces watery saliva content, increasing the concentration of salivary mucins and other proteins, a recent study has suggested that it is also a result of altered secretion of salivary mucin secretion (Ligtenberg et al., 2015). The effect of exercise on salivary secretion has been mainly studied at the level of salivary proteins with antimicrobial and mucosal defense functions. The effects at the level of salivary Immunoglobulin A (sIgA) secretion are reported by different authors, with prolonged, high-intensity exercise bouts decreasing sIgA secretion (Nieman et al., 2006), and short exercise bouts or low- to moderate-intensity exercise increasing sIgA levels (Allgrove et al., 2008). This indicates that not only the practice, but also the type and duration of exercise produce changes in salivary composition that may further affect the general functions and properties of saliva. The influences of physical exercise on salivary secretion may further differ according to the fitness of the individual (Kunz et al., 2015).

4.4. Saliva and Taste Perception

Saliva has a role in the oral perception of foods. This fluid is necessary to dissolve the substances that will be further transported to the places of reception/detection of taste (taste receptor cells in taste buds).

The involvement of saliva in oral food perception has begun to be studied in the context of astringency development, due to the participation of salivary proteins in the development of this sensation. Different salivary proteins have been identified as being involved in astringency from polyphenols, due to their affinity with these compounds: proline-rich-proteins (PRPs) (Williamson, 1994), histatins (Yan and Bennick, 1995), staterins, and cystatins (Soares et al., 2012), or even amylase (Soares et al., 2011). Of these, salivary PRPs have been the most studied in terms of interaction with polyphenols, constituting the main family of salivary proteins involved in astringency.

Apart from the proteins reported to be involved in astringency, other salivary proteins have been suggested as participating in oral food perception. The protein lipocalin 1, secreted by Von Ebner minor salivary glands, presents homology with hydrophobic molecule transporters, which are suggested as participating and helping in the concentration and transport of sapid molecules to taste cells (Schmale et al., 1990). Besides promoting lubrication, mucins, which are mainly high molecular weight glycoproteins, also participate in

the perception of food texture (Mese and Matsuo, 2007). Salivary amylase is a protein that is also involved in food perception. The involvement of this protein in food sensorial perception has been suggested by different authors, namely due to its influence on the perception of viscosity from starch-based foods (Engelen et al., 2007).

Carbonic anhydrase VI (CA VI) is a protein that is widely reported as being linked to bitter taste perception. Some authors observed that individuals with a deficit in CA VI presented altered anatomy of taste buds and taste function, and that such changes might be reversed by zinc treatment (Henkin et al., 1999). Moreover, this protein was observed in reduced levels in patients with taste dysfunction (Shatzman and Henkin, 1981). Levels of salivary CA VI have been also associated with differences between individuals in their capacity to taste the bitterness of the compound 6-n-propylthiouracil (PROP). Padiglia and colleagues (Padiglia et al., 2010), although they did not observe differences in the amounts of salivary CA VI between individuals sensitive and non-sensitive to the PROP bitter taste, observed differences between these groups in the capacity of salivary CA VI to bind zinc, which seems to affect its function. In the same line, a group of Italian researchers observed that different polymorphisms in the gene that codes for the salivary protein CA VI, which change the function of this enzyme, are related to the PROP taste response (Cabras et al., 2012). However, some controversy exists about the influence of this protein in bitter taste, with some studies lacking any observation of such a relationship (Feeney and Hayes, 2014).

Epidermal Growth Factor (EGF), secreted by parotid and submandibular glands, has been related to the morphological integrity of taste buds, being potentially involved in taste perception (Morris-Wiman et al., 2000). The possible interaction between salivary proteins and tastants, which can affect taste perception, was proposed for proteins such as histatin (Wada et al., 2010, cited by Dsamou et al., 2012). This protein was suggested as having an affinity with molecules such as quinine, possibly preventing it from reaching taste receptors. Melis and colleagues (Melis et al., 2013) reported the interaction of the molecule PROP with the amino acids arginine and lysine, suggesting that this interaction may induce changes in the conformation of the molecule, which may help it to interact with taste receptors.

A relationship between saliva composition and fat perception has been suggested, with the protein zinc- α 2 glycoprotein being observed at higher levels in individuals with a high sensitivity to the taste of oleic acid (Mounayar et al., 2013).

Salivary cystatins, which had already been reported as possibly involved in astringency (Soares et al., 2012) were associated with the perception of caffeine bitter taste in adult men, with the individuals presenting lower sensitivity to this taste having higher levels of this salivary protein (Dsamou et al., 2012). It was suggested that the relationship of this protein to taste sensitivity is due to the activity of cystatins as protease inhibitors, preventing the action of proteases that may be needed for decreasing the tightness of the salivary film that covers taste receptors, and consequently allowing the tastants to access taste pores (Dsamou et al., 2012). This possible relationship between salivary cystatins and bitter taste perception was reinforced by studies reporting higher acceptance of bitter taste by children with high levels of salivary cystatins (Morzel et al., 2014; Mounayar et al., 2014). However, this issue needs to be deeply studied, as controversy exists in terms of the participation of salivary cystatins in the perception of bitter taste elicited by other compounds, such as PROP. In this case, some studies report no differences in salivary cystatin levels between individuals with high and low responsivity (Cabras et al., 2012), whereas our research team observed different salivary

responses in terms of cystatin secretion after stimulation with PROP bitter taste (data not published).

4.5. Changes in Saliva Composition in Obesity and Bariatric Surgery

Metabolic state can induce changes in saliva, with the consequent changes in the functions of this fluid. Nutritional condition and problems associated with it, such as malnutrition (Psoter et al., 2005), and obesity (Choromańska et al., 2015; Vors et al., 2015) have been observed as relating to changes in saliva composition.

Energy-protein deficit elicits changes in the levels of some salivary proteins, which is different according to the level of severity of malnutrition (Fonteles et al., 2012). Undernutrition in anorexia nervosa has been also associated with altered function of major and minor salivary glands, resulting in changes in the pH and composition of oral medium. Unstimulated flow rate is significantly lower in anorectic patients, with these individuals also presenting lower activities of enzymes such as collagenase and aspartate amino transferase (Elżbieta et al., 2015).

Saliva flow rate, total protein concentration and levels of salivary proteins such as alpha amylase, cystatins, and carbonic anhydrase VI (CA VI), among others, have been observed to be changed in obese individuals (Lamy et al., 2015; Rodrigues et al., 2015). Besides CA VI levels being elevated in obese individuals (Lamy et al., 2015; Vors et al., 2015), a strong positive correlation was observed between the levels of this protein and Body Mass Index (BMI), suggesting that salivary concentration of CA VI increases with BMI (Lamy et al., 2015). Higher levels of this protein, which have been associated with sensitivity to bitter taste, may suggest a relation between changes in obese saliva composition and bitter taste perception. Differences in the levels of salivary amylase, or salivary cystatins (Lamy et al., 2015), which have also been suggested as being related to oral food perception at the level of starchy foods (Mandel et al., 2010) and bitterness (Dsamou et al., 2012) respectively, supports this hypothesis. Vors and colleagues (Vors et al., 2015) reported lower lipolysis and higher proteolysis in the saliva of obese individuals in comparison with that of normal-weight subjects. Salivary lipolysis was reported as having a positive relation with fat intensity perception (Neyraud et al., 2012), which may suggest that saliva from obese individuals may result in different oral fat perception.

Various other nutrition-related pathologies have been also studied in terms of changes in saliva composition, which is beyond the scope of this chapter. This is reviewed in different publications (e.g., Javaid et al., 2016; Schipper et al., 2007; Zhang et al., 2013).

Despite the scarcity of studies about saliva composition after bariatric surgery, those that exist report partial reversion of the changes in this oral fluid composition that had been previously induced by obesity. Saliva total antioxidant status and the total amount of superoxide dismutase 2, which seems to be increased in obese patients, appears to decrease after bariatric surgery (Knaś et al., 2016), with the differences observed for the proteins salivary alpha-amylase and carbonic anhydrase VI in obese women no longer observed after gastric sleeve bariatric surgery (Lamy et al., 2015). Changes in saliva composition induced by bariatric surgery can also result in changes in food aroma perception. Aroma release is affected by several factors already mentioned in previous parts of this chapter. One of them appears to be saliva composition. An interesting study showed that the perception of aroma

by obese individuals may be altered in comparison with normal-weight subjects due to differences in saliva composition (Piombino et al., 2014). In that study, the different perception of wine aromas by obese individuals was related to the differences in their saliva protein composition, and a possible role of some of the proteins in binding volatiles, impeding them from accessing receptors, was hypothesized. Although potential changes in aroma perception after weight loss have not been evaluated, it is possible that they may also occur, as the saliva composition changes.

Based on the information set out above in relation to alterations in hormones and gastrointestinal peptides following bariatric surgery, about how hormones may influence taste perception and saliva secretion, and how taste and saliva may be related, more studies about saliva changes after different types of bariatric surgery may be useful for better understanding the modifications in oral food perception usually reported for this type of weight loss.

CONCLUSION

Bariatric surgery is, thus far, the most effective method for sustained weight loss and treatment of comorbidities associated to obesity. Although different factors contribute to this, differences in the way in which food is perceived at oral cavity level contribute to changes in dietary patterns. Oral food perception is influenced by hormonal parameters, and changes in these, resulting from bariatric surgery, have an influence at taste and odor level.

Although less well explored, saliva composition is also modified, at some level, after different types of bariatric surgery. Further studies are needed to better understand how these salivary changes are relevant to altered food perception and for the overall process of weight loss after bariatric surgery.

ACKNOWLEDGMENTS

This chapter is funded by FEDER financing through the Operational Programme for Competiveness Factors-COMPETE and national funding through FCT-Foundation for Science and Technology under the project UID/AGR/00115/2013 (ICAAM – University of Évora). The authors also acknowledge financial support from the Portuguese Science Foundation (FCT) in the form of Elsa Lamy FCT investigator contract IF/01778/2013. The Portuguese Science Foundation (FCT) played no role in the development of this work or in its submission for publication.

Chapter 439

**INTEGRATIVE VIRTUAL REALITY THERAPY
PRODUCES LASTING BENEFITS FOR A YOUNG
WOMAN SUFFERING FROM CHRONIC PAIN AND
DEPRESSION POST CANCER SURGERY:
A CASE STUDY**

ABSTRACT

In this chapter we present a case study, which was part of an evaluation of the BrightArm Duo Rehabilitation System for treating the effects of chronic upper body pain following breast cancer surgery. The subject was a 22-year old woman with burning and stabbing pain in the right upper arm. Training consisted of playing custom bimanual 3D games while seated at a gravity-modulating robotic table. The therapy consisted of 16 sessions over eight weeks. Standardized assessments demonstrated a meaningful improvement in the motor, cognitive and emotive domains with a statistically significant reduction in pain. Gains transferred to daily activities enabling the subject to resume full time employment, driving and socializing.

INTRODUCTION

The psychological, social and behavioral impact of cancer at a young age can be tremendous (1). As the number of young cancer survivors increases, their quality of life after cancer treatment becomes an important concern (2). With improved detection and progress in management of breast cancer (3), the survivors need improved rehabilitation approaches to address and overcome the resulting complications from that treatment. Depression and chronic pain in shoulder and arm following breast cancer surgery are prevalent and can lead to life-long psychological, cognitive and physical impairments. It is important to have rehabilitation techniques that can produce long lasting benefits for women, while being graduated in difficulty, interactive and fun.

Virtual reality (VR) offers benefits for other diagnostic conditions and provides a new and unique opportunity in the rehabilitation of women with breast cancer. VR analgesia, pioneered by Hoffman (4) for burn wound care, has subsequently been used to reduce chemotherapy-related distress in women with breast cancer (5). Virtual reality has great potential for use in acute and chronic pain by providing a non-opioid ‘virtual analgesic’ response (6). Virtual reality therapy has been tried in breast cancer to alleviate symptoms during chemotherapy (5). However, to the authors’ knowledge no clinical trials have been conducted to study VR effectiveness in breast cancer survivors with chronic upper body pain and related depression.

The BrightArm Duo Rehabilitation System (Bright Cloud International, New Jersey, USA) is an experimental robotic platform that modulates gravity loading on the upper extremities (UEs). The ability to unload gravity makes it appropriate for individuals with weak arms and diminished ability to grasp, such as those suffering from chronic UE pain. BrightArm Duo uses VR to engage the patient in upper body bimanual integrative exercises that provide motor and cognitive training and affective relief. This integrative virtual rehabilitation has been found to be beneficial in prior BrightArm Duo studies of elderly individuals with chronic stroke residing in skilled nursing facilities (7). These earlier studies have shown benefits to cognition and depression reduction, which in theory could benefit breast cancer survivors with the same type of impairments. Thus, a feasibility study was conducted (N=6) to explore the feasibility of BrightArm Duo Rehabilitation System for the treatment of chronic pain in breast cancer survivor post-surgery, and who also have depression and cognitive deficits. The case described here was the youngest subject participating in that study.

OUR STUDY

The BrightArm Duo Rehabilitation System consisted of a robotic rehabilitation table, two computerized forearm supports, a 27” monitor, a laptop computer for the therapist, a remote clinical server and a library of custom integrative rehabilitation games. The library of custom games was developed in Unity 3D (8) for uni-manual and bi-manual motor (shoulder, elbow, grasp), emotive (depression) and cognitive (executive function, focusing, short-term and delayed memory, working memory and task sequencing) training. The subject interacted with these serious games through active arm movement and power grasp, both being tracked in

real time. The forearms of the subject were placed onto low-friction supports outfitted with two 770 nm LED towers and a rubber pear bulb connected to an internal differential pressure sensor. The hand position was determined with better than 0.5 mm accuracy. Subject's grasp strength of the rubber pear was measured by the pressure sensor and communicated wirelessly to the laptop station at a data rate better than 40 packets per second. Each session, the system automatically adapted to the subject's forearm movement and grasp capabilities. Game difficulty, session duration, gravity unloading/loading (gravity assistance/resistance during training) on her upper extremity, were all gradated over the length of the training (7). Tilting upwards provided resistance when moving away from the trunk. Conversely, tilting downwards assisted weak arm movement.

Figure 1. BrightArm Duo Table tilted upwards with two arm supports for user interaction and therapist laptop rendering Pick & Place game to the 27" monitor. © Bright Cloud International Corp. Reprinted by permission.

Figure 2 shows the screen images of the nine games used in the study. In *Breakout 3D*, the subject bounced a virtual ball toward an array of crates using paddle avatars. The game trained shoulder abduction/adduction or flexion/extension depending on the orientation of the crates, as well as focusing and executive function. The matching card games *Card Island* and *Remember that Card* trained short-term and delayed visual and auditory memory, grasp strength, shoulder abduction/adduction, and shoulder flexion/extension. For *Musical Drums*, the subject controlled drum stick avatars to strike a series of notes that drifted across (up to four) drums. This game trained focusing and motor control. The *Xylophone* game trained short-term auditory and visual memory by having the subject repeat a sequence of musical notes using mallet avatars. In *Pick & Place*, the subject grasped a ball from among multiple choices and then moved it to a fixed target of matching color, using shoulder flexion/extension or abduction/adduction arm movements. The game trained working memory and motor control as subject was asked to follow an ideal straight line to the target. Playing *Arm Slalom* induced shoulder rotations in order to guide a skier avatar through a

downhill slalom course. In the *Avalanche* game, the subject controlled pickaxe and shovel avatars through grasp and arm movements. The task was to break and clear a series of ice walls so to free people trapped in a cottage. In *Treasure Hunt*, the subject used one or two shovel avatars to clear sand and uncover a series of buried treasures, before they were buried again by periodic sand storms.

Training Protocol

The feasibility study followed a single subject A1-B1-A2-A3 design with training (B1) consisting of a total of 16 sessions, two sessions per week for 8 weeks. Standardized assessments of motor, cognitive and emotive state were performed pre-training (A1), post-training (A2) and at 8-week follow-up (A3). The training sessions progressed from 20 minutes to 50 minutes in duration, and the BrightArm Duo robotic table was tilted upwards progressively from a minimum of 0° (horizontal) at the start of the protocol to a maximum of 20° in the last training sessions. This corresponded to gravity unloading at the beginning of the therapy then progressively increased gravity loading as the subjects trained in later sessions. The Western Institutional Review Board, an independent board overseeing research involving human subjects, reviewed and approved the study protocol in accordance with Federal Guidelines. The subject was recruited at the University Pain Medicine Center (Somerset, NJ) and training took place at Roosevelt Care Center, a clinical facility in Edison, NJ in summer 2015. The subject received a \$25 monetary compensation for each session attended however to the authors' knowledge this was not her primary reason for participation. The subject was genuinely interested in this experimental therapy to help manage her upper body pain symptoms.

CASE STORY

The subject was a 22-year old single woman of a mixed race, African American and White, with post-surgical chronic pain for the preceding 9 years. This chronic pain was localized to right upper arm and was burning, throbbing and stabbing in nature. She occasionally also reported pain in lower back, upper back, breast, hip and neck which was described as nagging. The subject reported that moving made her pain worse and nothing made it better. She had severe depression, difficulty socializing and had one suicidal attempt. As a consequence of her pain she kept her right arm in a sling which resulted in employment difficulties. She worked as a certified nursing assistant in home health care with hourly work that she would have to cancel many times due to pain. She was recruited from the University Pain Medicine Center where she followed up routinely with a pain medicine physician with a reported pain level of 6 to 8 on Numerical Pain Rating Scale (9) and not undergoing any physical or occupational therapy at the time of her enrollment in the experimental study. The surgical procedure on her breast reported when she was 13 years old did not have any medical records for verification of diagnosis. She underwent lumpectomy of her right breast again in 2008 and cyst removal from left breast in 2007. She reported taking Tromadol 50 mg and Percocet 10 mg at pre-training. She had tried multiple therapies in the past as indicated in her clinical notes. These ranged from pain medications, to physical therapy twice a week for 10 weeks from January to April 2014, to home exercises.

Data Collection Instruments

Therapy session data (B1) included supported arm reach baseline on the BrightArm Duo table (as measured by overhead digital cameras used in tracking), power grasp strength baseline (as measured by a forearm support grasp sensor), heart rate and blood pressure. In addition B1 data included the number of active movements and grasp repetitions for each arm during a session, as well as game performance data (score, errors, completion time) collected during play. Pain was assessed using the Numeric Pain Rating Scale (NRS) administered verbally by the attending OT. This pain measure has validity in measuring cancer-related pain intensity (9). Skin temperature was measured during the sessions with basis wristwatch that was worn on the subject's unaffected arm. Blood pressure and pulse were measured before and after each session using Omron 7 Series upper arm blood pressure monitor.

Occupational therapy evaluations were done pre-training, post-training and at eight week follow-up by a blinded Senior Occupational Therapist (OT) consultant who was not training the subject. This OT evaluation involved assessment of upper extremity function using the Fulg-Meyer Assessment - Upper Extremity Section (FMA)(10), the Chedoke Arm and Hand Inventory – 9 (CAHAI-9)(11) for bimanual tasks and the Jebsen Hand Function Test (JHFT)(12) for hand function. Arm and hand range of motion were measured using mechanical goniometers, shoulder strength was assessed using wrist weights, grasp strength was measured with a Jamar mechanical dynamometer and a Jamar pinch meter. In addition the subject was assessed for her degree of independence in activities of daily living (ADL) involving the upper extremity, using the Upper Extremity Functional Index 20 (UEFI-20) (13).

Neuropsychological evaluations were done by a blinded research assistant under the supervision of a licensed clinical neuropsychologist pre-training, post-training and at follow-up. These were measures of depression severity, attention/concentration, processing speed, learning, memory, and executive function. The standardized measures used were the Beck Depression Inventory, Second Edition (BDI-II), (14) the Neuropsychological Assessment Battery Executive Functioning Module (Generation subtest) (15), the Hopkins Verbal Learning Test, Revised (HVLT-R) (16), the Brief Visuospatial Memory Test, Revised (BVMT-R) (17), the Trail Making Test A and B (TMT) (18). Alternate test forms were used whenever possible to minimize test-taking practice effects. Raw scores were utilized in all data analysis. Both evaluating clinicians were blinded to the therapy methodology and scope.

At the end of weeks 4 and 8 of VR training, the subject rated her experience on a custom paper-based subjective evaluation questionnaire with ten questions. The questions were: 1) “The system was easy to use?”; 2) “Playing games with my affected arm(s) was easy?”; 3) “I had no pain or discomfort in my upper body?”; 4) “Instructions given to me were useful?”; 5) “Playing games with both arms was easy?”; 6) “I was not bored while exercising?”; 7) “The length of the exercising in a day was appropriate?”; 8) “There were few technical problems?”; 9) “I would encourage others to use it?”; 10) “I liked the system overall?” Each question was rated on a 5-point Likert scale, from 1 meaning “strongly disagree” (least desirable outcome) to 5 meaning “strongly agree” (most desirable one). The subject could add free form comments on the evaluation form.

FINDINGS

The subject exercised a total of 20,130 active arm repetitions and 7,020 hand grasps. The BrightArm Duo tilt was gradually increased over the study span, from 0° initially to 20° upwards at the end. Figure 3a show active arm repetitions increased from about 320 in session 1 to over 1,500 repetitions in session 16 with peak activity around session 5 and 11. Hand grasps increased from 45 in session 1 to 971 by session 16. The intensity of play increased with session number as well. If session length is normalized to maximum duration of 51.2 minutes, arm movement and hand grasps would increase along a slope of 878 ($p=0.18$) and 1,011 ($p<0.001$) repetitions between session 1 and 16. The subject played a total of 412 games over a total of 567 minutes. The exercising duration steadily increased from 21.2 minutes/session at the start to 51.2 minutes/session at the end. Both game difficulty and subject performance increased over the study. Figure 3b illustrates how composite games scores increased from 43 (session 1) to 65 (session 16). The linear regression fit of the data points yielded a statistically significant trend line ($p<0.001$) corresponding to a 22 point increase in average game score from about 47 points in session 1 to about 69 points in session 16.

Pain and Skin Temperature Outcomes

The subject’s reported pain and skin temperature were captured every session. Figure 4a illustrates the reported maximum upper extremity pain on the 10 point Numerical Pain Rating

Scale by session number. As seen by the statistically significant trend line ($p=0.01$), there was marked reduction in reported pain of 4.4 points over the course of the study. The increase in reported pain towards the end of the experimental therapy coincided with the subject stopping taking her pain medication. Figure 4b plots the average skin temperature by session number as measured at the wrist of the subject's unaffected arm. The linear regression fit of the data points yielded a statistically significant trend line ($p=0.001$) corresponding to a 10.25°F increase in skin temperature over the 16 sessions. This is indicative of increased blood flow to the upper extremities in response to increased use of the affected arm.

Figure 3. a) Arm and hand repetitions and b) composite game score by session number for the cancer survivor experiencing post-surgery chronic pain. © Bright Cloud International Corp. Reprinted by permission.

Upper Extremity Active Range of Motion

The subject's range of motion was evaluated for the affected and unaffected arms at pre-training (A1), post-training (A2) and follow-up (A3). The elbow and finger values were within normal limits. In Table 1, 10 of 12 range of motion measures improved at A2 and A3 relative to A1. The affected arm maintained substantial gains at A3: Abduction (111°),

Flexion (89°), Adduction (40°), External Rotation (31°), and Extension (19°). The unaffected arm improvements were more modest at A3: Flexion (16°), Abduction (10°), Extension (9°) with Internal Rotation moderately decreasing (20°). The minimal clinically important difference (MCID) is 8° for shoulder range of motion improvement (19).

Upper Extremity Strength

Table 2 lists arm and hand strength for the affected and unaffected arms pre-training (A1), post-training (A2) and follow-up (A3). All ten strength measures improved or remained the same as compared to A1. At follow-up, the gains in grip strength compared to pre-training were 231.3 N and 97.9N for the affected and unaffected hands, respectively. These results are 200% to 400% the MCID of 49 N for hand grip (20). At follow-up, the affected and unaffected hand two-finger pinch improved 29.8 N and 20.0 N, respectively and the 3-jaw pinch improved 36.5N for both hands, compared to pre-training. The affected shoulder strength had an impressive gain from 4.4N at A1 to 31.1N at A3, a 700% increase. The unaffected shoulder strength improvement was from 31.1N to 44.5N represents a more modest 40% increase.

Table 2. Hand and arm strength for the post-surgery cancer survivor experiencing chronic pain. © Bright Cloud International Corp. Reprinted by permission

Variable	Affected Shoulder					Unaffected Shoulder				
	A1	A2	A3	A2-A1	A3-A1	A1	A2	A3	A2-A1	A3-A1
Hand Grip	68	262.4	299.4	+194.4	+231.3	115.7	218.0	213.5	+102.3	+97.9
Tip Pinch	0.0	31.1	29.8	+31.1	+29.8	11.1	23.6	31.1	+12.5	+20.0
3 Jaw Pinch	4.4	46.7	40.9	+42.3	+36.5	16.9	34.7	53.4	+17.8	+36.5
Ant. Deltoid	4.4	22.2	31.1	+17.8	+26.7	31.1	31.1	44.5	0.0	+13.3
Lat. Deltoid	4.4	22.2	31.1	+17.8	+26.7	31.1	31.1	44.5	0.0	+13.3

Upper Extremity Functional Assessments

Functional assessments also improved at post-training (A2) and follow-up (A3) relative to pre-training (A1). Fugl-Meyer Assessment scores were 47 (A1), 58 (A2) and 56 (A3). The 11 and 9 point improvement at A2 and A3 respectively meet the MCID criteria of 9 points (21). CAHAI-9 scores were 50 (A1), 63 (A2) and 63 (A3). The improvement of 13 points at A2 and A3 is twice the MCID of 6.3 points (22), and is indicative of improved ability to perform bimanual ADLs. The metric UEFI-20 measurements were 18 (A1), 58 (A2) and 42 (A3). The improvement of 40 and 24 points at A2 and A3 were three to five times the MCID of 8 points (13). The JHFT for the affected hand was 79 (A1), 35 (A2) and 39 (A3) seconds. The subject was able to complete the manual tasks of JHFT in half the time post-training, and the speed improvement was maintained at follow-up.

Cognitive and Emotive Outcomes

Table 3 lists emotive and cognitive measures evaluated pre-training, post-training and follow-up. There was a notable reduction in depression severity of 16 points (A2) and 6 points (A3). Both values were above MCID of 5 points for BDI-II (23). The Trail Making Test Part B showed a reduction in time from 128 seconds at A1 to 49 seconds at A3. This was indicative of improved attention and processing speed. HVLT-R which measures verbal

learning and memory was one cognitive measure that showed a systematic decline from 22 points at A1, to 20 points at A2, and 16 points at A3. This was offset by an increase in word generation from 5 at A1, to 6 at A2 and 9 at A3. There was a systematic increase BVMT-R, from 13 points at A1, to 18 points at A2 and 20 points at A3, indicative of improved visuo-spatial memory.

Subject Attendance and Testimonial

The subject completed the 16 sessions of the protocol over a period of nine weeks. She postponed two sessions early on due to back pain related to work and unrelated to BrightArm training. She reported no side-effects from the VR therapy such as cyber sickness or headache. The subject evaluated the system by answering the ten questions. The average response was 3.6/5 at the two sampling times (week 4 and week 8). The lowest scores were for the questions: “I had no pain or discomfort in my upper body?” (1.5), “Playing games with my affected arm(s) was easy?” (2.0), “I would encourage others to used it?” (3.0), “The length of the exercising in a day was appropriate?” (3.5). The responses averaged a rating of 4 between week 4 and 8 for the questions: “The system was easy to use, “Playing games with both arms was easy?,” “There were few technical problems?,” “Instructions given to me were useful?.” The highest evaluation score was 5.0/5 for the questions: “I was not bored while exercising?” and “I liked the system overall?” which shows excellent technology acceptance of the BrightArm Duo.

At follow-up (A3) the subject was asked if she would provide a testimonial. In compliance to IRB Human Subject’s Regulations her identity is not disclosed, although she included her name in the email sent in late May 2015. This email is included here with subject’s approval, as it provides her opinion on the impact that the experimental therapy had on her life.

“I’ve just completed my 8 weeks of physical therapy. This therapy section helped me tremendously. Before I started this therapy my right arm had no use me and there was so much pain! There were things I couldn’t do like driving, getting dressed, taking a shower, playing with my nephew....I was working on and off, I couldn’t hang out with my friends, my life basically stopped, and it was very depressing. But now I’m driving, I’m back working full time, I’m catching up with friends AND there’s no pain. I’m extremely happy with the results, this is my third time trying therapy for my arm and this the only one I saw results from. The therapy sessions consist of games....yes you are literally sitting in a chair in front of a computer playing games, though they were challenging it was also very fun, well for me it was. Dr. Burdea and his team gave me back my life because I

thought it was over literally. I recommend everyone that's having this problem to try this therapy session, it works tremendously and it is fun (did I mention it's actually games you play on a computer) yes and everyone is very friendly. So thank you Bright Cloud International."

The subject was referring to BrightArm Duo in the physical therapy reported in this testimonial. She has compared VR games to the traditional physical therapy she had undergone in the past which did not work for her. The immersive games induced bilateral high repetitions and engaged the participant with rewarding feedback for effort. These features made the rehabilitation training with BrightArm Duo distinctly different from her prior traditional therapy.

DISCUSSION

Childhood cancer survivors have an increased risk of complications later in life and rehabilitation with better outcomes will greatly improve the quality of life in these women (24). In this study, the 22-year old female subject showed marked reduction in shoulder and arm pain of 4.4 points on the NRS scale which is much higher than the MCID of 2.17 for NRS established for people with surgical and post-surgical shoulder pain (25). This is an encouraging finding considering the impact of VR therapy on chronic pain in other conditions such as fibromyalgia has shown no benefits for pain intensity (26). However, the benefits of VR therapy in cancer related pain during acute painful procedures, hospitalization and chemotherapy has been studied and shown to be beneficial (27). Visual distraction has been one of the theories put forth for explaining these beneficial effects on pain (6). Although, in this study, the positive effect on pain intensity cannot be completely attributed to the phenomenon of visual distraction. As reported in literature (28), the distraction from pain could be insufficient to cause the accompanied improvements on motor and cognitive aspects of function measured at post-training and maintained at 8-week follow up. It is also likely that the 16-session protocol used in this study resulted in better outcomes than the 10-session protocol reported in other studies of VR in chronic pain of fibromyalgia (29).

Garcia-Palacios et al. (26) reported no benefit of VR therapy on depression in people with chronic pain due to fibromyalgia, whereas in this study, the depression scores decreased by 16 points on the BDI-II, which is a 32% improvement. The MCID for depression varies with initial severity (30) and has been estimated to be 32% for individuals with prolonged depression which fits the profile of the subject in this study. A recent review by Chirico et al. (27) summarizes the benefit of VR therapy in cancer on psychological variables such as state anxiety and painful procedures, the results of the present case study open the possibility to understand the impact of VR therapy in other variables such as depression. They also recommend including bio physiological variables in VR therapy research in cancer using biosensors for understanding physiological responses to the training. In this study, biosensors at the wrist of the unaffected arm showed a 10.25°F increase in skin temperature with the over the course of the 16 sessions conducted in the same indoor therapy room. This interesting finding is indicative of an increased thermal response during exercise that is likely during moderate to high intensity exercise (31) and was associated with improved outcomes

in the subject. This may indicate increased blood flow to the arm with a beneficial effect for overall health of the arm (32).

An average of 1,260 active arm repetitions and 440 hand grasps per session for the subject over the course of 16 sessions is an important characteristic of the BrightArm Duo therapy. This large number of induced arm repetitions has previously been reported (7) to benefit elderly stroke survivors in the chronic phase. The substantial benefits of this intensive therapy are indicative of application for chronic cancer pain populations as well. All standardized measures in this case study of range of motion, strength, UE function, attention, and memory improved at post-training. With the NRS pain level of 6 and 7 pre-training, the subject was unable to move her right arm and post training the regained range of motion in the arm along with simultaneous distraction from pain has shown to be the right combination of therapy for her. As seen from her own testimonial, the subject was able to transition to a full time job and returned to driving giving her maximal functional independence much desired at her young age.

A remarkable finding in this case study was that at 8-week follow up (A3) the majority of gains remained higher than A1, with no VR training for eight weeks (after A2). The subject did not report playing any form of videogames during the no-VR phase and enjoyed reading and socializing for recreation. The maintenance effect with VR therapy has been shown in prior studies in 48 hour follow-up (5), however, to the authors' knowledge, a 8-week follow up has not been reported previously. The study of VR maintenance effect for rehabilitation therapy programs is as critical for chronic pain conditions as it is for rehabilitation of conditions such as stroke. This case study is supportive of the feasibility of a longitudinal study protocol to study these maintenance effects of VR therapy in chronic pain and depression.

This study, part of an n=6 feasibility evaluation of the BrightArm Duo system for upper body chronic pain, has obvious limitations to generalizability. However, the information detailed in this case study brings forth the qualitative aspects associated with BrightArm Duo training especially in younger individuals and helps examine the feasibility of the VR therapy in this sample of cancer survivors. The therapists can benefit from an in-depth study of successful cases using BrightArm Duo system in rehabilitation to maximize benefits for their clients. In conclusion, initial findings demonstrate a meaningful reduction in chronic pain and physical, cognitive and psychological improvement for a young female subject. These outcomes suggest a need for controlled studies in young subjects with pain and depression associated to post-surgical treatment of breast cancer.

Chapter 440

IS MINIMALLY INVASIVE PARATHYROIDECTOMY FEASIBLE IN PATIENTS WITH PREVIOUS IPSILATERAL THYROID SURGERY?

***Roberto de la Plaza Llamas*, José Manuel Ramia Ángel,

ABSTRACT

Introduction. Prior ipsilateral thyroid surgery (PITS) has habitually been considered a contraindication for minimally invasive parathyroidectomy (MIP) in patients with primary hyperparathyroidism (PHPT).

Material and Methods. We performed an unlimited PubMed search updated on March 31, 2017, with the following strategy: ((Minimally invasive parathyroidectomy) OR (Focused parathyroidectomy) OR (Targeted parathyroidectomy)) AND ((Thyroid surgery) OR (Thyroidectomy) OR (Cervical endocrine surgery) OR (Reoperative neck)). A total of 563 articles were obtained.

Results. We found only four articles reporting MIP for PHPT in patients with PITS. Two of them correspond to the same series, which was recorded in full in the second article. Despite the limited results, we analyzed the studies in search of evidence supporting or contraindicating the use of MIP in patients with PITS.

In the literature on MIP, only 33 patients with PITS have been reported. Only one complication has been described, a temporary recurrent laryngeal nerve paralysis. All patients were discharged within 24 hours. Mean duration of the procedure and length of stay (in the studies in which it was recorded) did not differ from those cases without PITS.

* Corresponding Author's Email: rdplazal@sescam.jccm.es.

Conclusion. MIP seems to be a valid option in patients with PITS. Surgical difficulty does not appear to be increased in these patients. The limited dissection involved in MIP and the targeted nature of the technique in theory are clear advantages, with a decreased risk of complications, shorter hospital stay, and less scarring. There is also a saving on costs. However, further studies are required to reach firm conclusions.

1. INTRODUCTION

Minimally invasive parathyroidectomy (MIP) has been accepted as the procedure of choice for the majority of patients with primary hyperparathyroidism (PHPT) and single gland disease, and appears to have replaced bilateral neck exploration as the gold standard [1].

Prior central compartment surgery of the neck, such as parathyroid surgery via bilateral cervical exploration or total or ipsilateral thyroidectomy, is habitually considered a contraindication for MIP in patients with PHPT. This is because prior surgery may distort or eliminate the normal tissue planes, and may alter the location of the adenoma because of the scarring process accompanying the prior mobilization of the parathyroid glands or the thyroid [2]. Obviously this process is more pronounced in cases of ipsilateral thyroidectomy. It has generally held that reoperations for PHPT have lower cure rates (80% to 96%), higher rate of complications (5% to 10%), longer surgical time and higher costs significantly (2-3 times) than the first operation [3-7].

The aim of this chapter is to determine whether minimally invasive parathyroidectomy is feasible in patients with previous ipsilateral thyroid surgery (PITS), and to assess the results of series in which it has been applied.

2. MATERIAL AND METHODS

We performed an unlimited PubMed search updated on March 31, 2017, with the following strategy: ((Minimally invasive parathyroidectomy) OR (Focused parathyroidectomy) OR (Targeted parathyroidectomy)) AND ((Thyroid surgery) OR (Thyroidectomy) OR (Cervical endocrine surgery) OR (Reoperative neck)). A total of 563 articles were obtained.

Abstracts were reviewed and articles deemed relevant to the subject of this study were analyzed. Series containing patients who had undergone prior bilateral or ipsilateral surgery for adenoma removal were included. Series including contralateral thyroid surgery or surgery for other non-thyroidal causes were excluded, as were those that reported patients undergoing prior parathyroidectomy without thyroidectomy.

3. RESULTS

We found only four articles reporting MIP for PHPT in patients with PITS [1-2, 8-9]. Two of them [2, 8] correspond to the same series, which was recorded in full in the second article [2]. In all, 30 patients were studied (Table 1).

Briefly, the operative approach for MIP in the three series typically involved an incision of 2 to 4 cm, if possible taking advantage of the prior scar, although sometimes a caudal or cephalic incision was required [2]. Two types of approaches, central and lateral, were used. The central approach to the pretracheal fascia involved retracting the strap muscles laterally after separating them down the midline [2]. The lateral approach used the lateral aspect of the previous wound only and allows access to the deeper neck structures by entering the plane between the strap muscles and the sternocleidomastoid muscle [1-2, 9].

Norman et al. studied 21 patients referred for non-familial PHPT. Of these, 14 had persistent PHPT, three recurrent hyperparathyroidism and four PHPT without parathyroid surgery. The four patients with PHPT without parathyroid surgery were the only ones who had undergone PITS. All patients underwent a high-resolution sestamibi scan several weeks before the operation. The surgical procedure was radioguided MIP without intraoperative PTH monitoring (IOPTH). All patients were cured, as demonstrated by normal serum calcium and PTH levels after one week and three and six months after the procedure. Sixteen of the 21 patients were discharged within two hours of the operation. Four patients remained overnight as 23-hour admissions, mostly because their operations were performed late in the day and they were elderly [2].

In Dimas et al.'s retrospective study, 42 of 380 patients with PHPT had prior cervical surgery. Twenty-seven of these 42 were selected for MIP, while the other 15 underwent traditional cervical exploration. Selection criteria for MIP were unilateral single or two gland disease localized preoperatively by at least two imaging techniques. Imaging studies included high resolution neck ultrasound and sestamibi scan in most cases, and CT scan, selective venous sampling and MRI in seven patients. MIP was performed only when there was unilateral single or two gland disease and the adenoma(s) was preoperatively localized with two concordant imaging techniques, one of which necessarily was sestamibi scan. Endocrine neck operations had been performed previously in 24 patients in the first group (total or subtotal thyroidectomy) before the diagnosis of PHPT; one patient had a 2-stage planned unilateral approach under local anesthesia for parathyroid hyperplasia. Two patients had previously undergone surgery for other reasons: a highly positioned sternotomy and a tuberculosis neck mass with multiple abscesses. The type of operation performed included a unilateral approach under local anesthesia (22 cases) with one conversion to general anesthesia, and MIP under general anesthesia (5 cases). No gamma probes, IOPTH assays or frozen-section analyses were performed. Twenty-six of the 27 patients were normocalcemic after the operation. One patient had persistent PHPT. Mean duration of the procedure and length of stay were similar to those recorded in MIP in patients without previous neck surgery. No surgical complications or persistent hypoparathyroidism occurred. Mean hospital stay was approximately 20 hours (19-23 hours). All patients were considered for discharge on the first postoperative day after the morning measurement of blood calcium levels. Mean follow-up assessments at 40 months (4-89 months) did not reveal any recurrence [1].

In 62 patients operated on for PHPT, De la Plaza et al. used MIP with IOPTH in 55. Two patients had undergone prior total thyroidectomy for thyroid papillary carcinoma, one with central lymph node dissection. Preoperative localization was performed with sestamibi scan; ultrasound was negative in both patients. They were assigned to ambulatory MIP surgery with IOPTH, one radioguided. A temporary recurrent laryngeal nerve paralysis was recorded in another patient who underwent radio-surgery and who had previously undergone central lymph node dissection. Laryngoscopy performed at three months showed complete recovery, with normal mobility of the vocal cords [9].

Table 1. Patients in the literature underwent minimally invasive parathyroidectomy with previous ipsilateral thyroid surgery

Discharged	<23 hours (NS)	1 day	AS
Type of operation	MIRP	UALA: 22, MIP: 5	MIRP: 1, MIP: 1
IOPTH	No	No	Yes
Recurrence PHPT	No	No	No
Persistence PHPT	No	1	No
Follow-up (months)	6	40 (range 4-89)	18 and 25*

Central lymph node dissection: CLND; Temporary recurrent laryngeal nerve paralysis (TRLNP); NS: not specified; AS: ambulatory surgery; MIP: minimally invasive parathyroidectomy; UALA: unilateral approach under local anesthesia; MIRP: minimally invasive radioguided parathyroidectomy; IOPTH: intraoperative PTH monitoring.

* Updated data.

Taken together, the studies analyzed did not present evidence that contraindicated the use of MIP in patients with PITS.

4. DISCUSSION

With the use of preoperative imaging and IOPTH measurements, the surgical approach to PHPT has evolved from a standard bilateral exploration to a more focused image-directed approach [10]. However, surgery of the central compartment of the neck, particularly ipsilateral thyroidectomy, has been considered a contraindication for MIP.

MIP in patients with PITS has only rarely been reported in the literature. The published series of MIP either do not specify the history of PITS, automatically exclude patients with PITS [11] or warn that PITS may prevent the use of a minimally invasive approach [12]. The assignment of patients with persistent or recurrent PHPT to MIP is more common [13].

The search carried out in this chapter found that only 30 cases of MIP with PITS have been described in the literature, with a single case of morbidity [1-2, 9]. All patients were discharged within 24 hours. Mean duration of the procedure and length of stay, in the studies that specified them, did not differ from the cases without PITS [1]. In view of these results, the low level of use (or the low level of reporting) of focused parathyroidectomy in patients

with PITS comes as a surprise. This group of patients may represent a substantial proportion of the total: in Dimas et al.'s series, for example, 42 of 380 patients (11%) patients referred for PHPT had prior cervical surgery [1].

As we have seen, MIP has been carried out in patients with PITS even in cases in which only one preoperative localization study is available, with the support of radio-surgery and/or IOPTH [2, 9]. The European Society of Endocrine Surgeons recommends IOPTH assay for patients undergoing targeted parathyroidectomy on the basis of a single preoperative localization study [14]. If preoperative localization with sestamibi and ultrasound is not concordant and the surgeon wishes to perform a minimally invasive targeted procedure, IOPTH assay is recommended since the prevalence of multiglandular disease in this group is 17% [14-16].

MIP offers the following advantages: less scarring and thus better cosmetic results, less tissue dissection, lower level of pain, a significant decrease in the percentage of transient postoperative hypoparathyroidism to about 5% (compared with approximately 15 to 25% after bilateral neck exploration) and complete elimination of the risk of permanent hypoparathyroidism [17]. The biggest disadvantage is the risk of multiglandular disease.

CONCLUSION

The studies analyzed do not present any evidence to contraindicate MIP in patients with TIPS. Given its advantages over bilateral cervical exploration, MIP seems to be a valid option in patients with PITS, even when only one preoperative localization study has been performed. None of the 30 reports in the literature recorded any major surgical difficulties in patients with previous ipsilateral thyroid surgery. In theory, the limited dissection involved in MIP and the targeted nature of the technique represent advantages for the patient, with a lower risk of complications, shorter hospital stay and less scarring, and a decrease in costs. However, further studies are required to confirm these suppositions.

ABSTRACT

Postoperative cognitive dysfunction (POCD) is a mild form of perioperative ischemic brain injury, which emerges as memory decline and decreased attention during several months or even years after surgery. The present review summarizes our studies of POCD in patients after cardiac surgeries along with extensive review of the literature in this field. We found that at least three types of POCD may be outlined, and therefore tests sensitive to each type of POCD should be included into test batteries. Overall, the limitations of psychometric testing as a method of POCD definition include the lower baseline performance in cardiologic patients in comparison with matched healthy controls, the regression to the mean phenomenon and practice effects. Although the majority of studies of POCD have dichotomized cognitive outcome after surgery, classifying patients as “impaired” or “unimpaired,” this approach has a range of serious limitations, leading to discrepancies in case classification by different dichotomous criteria. In the last part of the article we present the results of retrospective analysis of our data in order to illustrate that widely used conversion of raw test scores into z-scores for combining different tests into a ‘cognitive domain’ may contribute to discrepancies in the results of studies of surgery outcomes. The same is true for the factorization of raw scores. Consequently, analysis of the raw (mean) scores and standard deviations is obligatory for any meaningful conclusions to be made, and other mathematical approaches should be used cautiously as an additional option.

Keywords: brain ischemia, memory decline, mild cognitive dysfunction, psychometric testing, psychomotor speed slowing

INTRODUCTION

Post-operative cognitive dysfunction (POCD) is a mild form of perioperative ischemic brain injury, which emerges predominantly as memory decline during several months, or even years after surgery (Bergh, Bäckström, Jönsson, Havinder, & Johnsson, 2002; Newman, Stygall, Hirani, Shaefi, & Maze, 2007; Sotaniemi, Monomem, & Hokkanen, 1986; Tsai, Sands, & Leung, 2010; Vingerhoets, de Soete, & Jannes, 1995). In addition, patients commonly report decreased concentration, attention span, and psychomotor speed. Both patients and spouses of patients notice postoperative memory decline after several months or even 1 year after operation (Bergh et al., 2002; Kastaun et al., 2016). Negative effects on driving abilities during several months after uncomplicated cardiac surgeries, were registered (Ahlgren, Lundqvist, Nordlund, Aren, & Rutberg, 2003), and patients with preoperative mild cognitive deficits were shown to demonstrate changed functional capacity in 1 year after cardiac surgery (Messerotti Benvenuti et al., 2013).

In young patients, cognitive function tends to be restored to its preoperative levels, in about 6 – 12 months after surgery (Herrmann et al., 2000; Kastaun et al., 2016; Mahanna et al., 1996; Neville, Butterworth, James, Hammon, & Stump, 2001; Newman et al., 2001a), however, in some patients POCD may persist, or even progress after 5 years of their operation with negative effect on the quality of life (Newman et al., 2001b). Increased mortality rate during a median of 7 - 8 year follow-up in patients with POCD, which was registered in 3 months after operation, was also demonstrated (Evered, Silbert, Scott, Maruff, & Ames, 2016; Steinmetz, Christensen, Lund, Lohse, & Rasmussen, 2009). In the same patient population, risk of leaving the labor market prematurely was twice as high among patients with 1-week POCD in comparison with patients without POCD.

Improved surgical technologies appear to minimize the number of cases with severe neurological complications and POCD in recent years even in high risk patient cohorts, and some studies showed improvement of cognitive functioning after cardiac surgery (Cormack et al., 2012). Nevertheless, the optimal tools for assessment of neurological and neuropsychological outcomes of surgical interventions are still needed at least when the effectiveness and the safety of surgical technologies and neuroprotective strategies are evaluated and compared. In addition, issues relating to the definition of POCD can be generalized to other fields where detection of subtle neuropsychological change is central (Lewis, Maruff, & Silbert, 2004).

Although some advanced neuroimaging and electrophysiological methods are available at present, the evaluation of patients with neuropsychological tests remains the most common approach for POCD definition. Using conventional pen and paper tests is much easier and cheaper in comparison with other diagnostic options, including computerized neuropsychological tests, and therefore any medical center all over the world may conduct research of POCD and compare neuropsychological consequences of different surgical and perfusion technologies.

Nevertheless, the evaluation of neurological outcomes of surgical interventions by perioperative psychometric testing is an intensively criticized approach. Experts point out the absence of a “gold standard” for effective application of this method in cardiac surgery studies (Arrowsmith, Grocott, Reves, & Newman, 2000; Blumenthal et al., 1995; Funder, Steinmetz, & Rasmussen, 2010; Collie, Darby, Falletti, Silbert, & Maruff, 2002; Lewis et al., 2004; Newman et al., 2007; Rasmussen et al., 2001; Slade, Sanchez, Townes, & Aldea, 2001; Tsai et al., 2010; Van Dijk et al., 2000), and many findings in this field were not confirmed by other similar studies, done by other research groups. Therefore, the contemporary methods of definition of POCD are considered to be highly arguable and unclear.

Here we summarize our experience with the evaluation of POCD in patients after coronary and open heart surgeries conducted in A. N. Bakulev Scientific Center of Cardiovascular Surgery in Moscow (Russia) in 2000 – 2010 (Bokeriia, Golukhova, Polunina, Davydov, & Begachev, 2005; Bokeriia et al., 2007; Bokeriia, Golukhova, & Polunina, 2009; Golukhova, Polunina, Lefterova, & Begachev, 2011; Golukhova, Polunina, Lefterova, Morelli, & Begachev, 2012; Polunina, 2008; Polunina, Golukhova, Guekht, Lefterova, & Bokeria, 2014) along with extensive review of the literature in this field. We found that at least three types of POCD may be outlined, and therefore tests sensitive to each type of POCD should be included into the batteries for studies of POCD. Also we discuss limitations of psychometric testing as a method of POCD definition, and these include lower baseline performance in patients with cardiac diseases in comparison with age and sex matched controls, regression to the mean phenomenon and practice effects, which may vary in magnitude in patients and healthy subjects. Although the majority of studies of POCD have dichotomized cognitive outcome after surgery, classifying patients as “impaired” or “unimpaired” on the basis of their baseline cognitive performance, this approach has a range of serious limitations, and considerable discrepancies in case classification by different dichotomous criteria of POCD were reported. In the last part of the article we present the results of the retrospective analysis of our data in order to illustrate that widely used conversion of raw test scores into z-scores for combining different tests into a ‘cognitive domain’ may contribute to discrepancies in the results of studies of surgery outcomes. The same is true for the factorization of raw scores, which have been used in few but very influential studies in this field.

PATHOPHYSIOLOGY AND TYPES OF POCD

In cardiac surgery POCD is caused predominantly by air and solid/fat particles microembolism emerging from the surgical wound and cardiopulmonary bypass, and the overall intraoperative microembolic load was shown to correlate with the cognitive decline after surgery in a range of studies (Barbut et al., 1997; Bokeriia et al., 2009; Fearn et al., 2001; Jacobs et al., 1998; Lee et al., 2003; Sylivris et al., 1998). Cerebral hypoperfusion, which impairs the clearance of microemboli from the cerebral circulation, (Blacker, Flemming, & Wijdicks, 2003; Caplan, & Hennerici, 1998; D'Agostino et al., 1996; Ganushchak, Fransen, Visser, De Jong, & Maessen, 2004; Omae, Mayzel-Oreg, Li, Sotak, & Fisher, 2000; Orlandi et al., 2005) and the systemic inflammatory response (Bruggemans, 2013; Parolari et al., 2007) are also discussed as important contributors to perioperative brain

damage. In addition, it was consistently shown, that pre-existing cerebrovascular disease with disturbed cerebral circulation considerably worsens effects of intraoperative brain ischemia on postoperative cognitive functioning (Evered, Silbert, Scott, Maruff, & Ames, 2016; Scott, Mathias, Kneebone, & Krishnan, 2016).

Neuroimaging studies consistently demonstrated an acute brain edema and global decrease of brain metabolism during the first three days after on-pump surgery (Anderson, Li, Hindmarsh, Settergren, & Vaage, 1999; Bendszus et al., 2002; Harris et al., 1998; Jacobs et al., 1998). In addition, 20 - 45% of on-pump patients demonstrated multiple small ischemic lesions postoperatively, and only 20% of them showed clinical signs of stroke or delirium (Bendszus et al., 2002; Floyd et al., 2006; Knipp et al., 2004; Restrepo et al., 2002; Stolz et al., 2004). Recently alterations in resting-state functional connectivity were demonstrated at 6-week follow-up after cardiac surgery (Browndyke et al., 2016). Hence, mild brain ischemic injury is common after on-pump surgery. Overall, the total volume of brain ischemic alterations correlated with clinical symptoms in several neuroimaging studies (Floyd et al., 2006; Stolz et al., 2004). It should be noted, that the problem of intraoperative cerebral microembolism, and POCD is not limited to cardiac surgery settings. For instance, the orthopedic surgery is associated with excessive fat microembolism (Scott et al., 2016; Kim et al., 2008; Koch et al., 2007; Koessler, Fabiani, Hamer, & Pitto, 2001). Indeed, any vessel or skin trauma may lead to air or fat embolism, especially when a wound is elevated in comparison to the heart level, and when multiple veins are open (Mirski, Lele, Fitzsimmons, & Toungh, 2007); mini-invasive manipulations may induce massive microembolism (Dube et al., 2004; Sowell, Lovelady, Brogdon, & Wecht, 2007), and POCD is also commonly found after non-cardiac and off-pump surgeries (Newman, 2007; Rasmussen et al., 2001; Tsai et al., 2010). Newman and colleagues (2007) reported that studies of major surgery outcomes showed POCD in 26 – 33% of patients compared with 7% for minor surgery, when patients were evaluated on the 7th – 21st day after surgery.

Our previous analysis of literature and our own data showed that at least three types of perioperative brain ischemic damage may be registered in cardiac surgery patients (Polunina et al., 2014). First, left hemisphere structures are more prone to perioperative ischemic strokes and microembolism in comparison with right hemisphere ones (Atochin et al., 2004; Leker, Pollak, Abramsky, & Ben-Hur, 1999; Lee et al., 2003; Rasmussen, Sperling, Abildstrom, & Moller, 2002; Weinstein, 2001), and the same is true for strokes in general population (Foerch et al., 2005; Hedna et al., 2013; Naess, Waje-Andreassen, Thomassen, & Myhr, 2006). It was hypothesized that slower circulation and greater metabolic demands in the left hemisphere neuro-networks, compared to right hemisphere ones, may predispose left hemisphere structures to greater risk of functional decrement after ischemic events (Hedna et al., 2013). In a series of our studies we registered the postoperative decline of digit span and verbal short-term memory in both open heart and coronary artery surgery patient cohorts, and this type of cognitive dysfunction correlated with either the microembolic load at left middle cerebral artery or the length of cardiopulmonary bypass time (Bokeriia et al., 2007; Polunina et al., 2014).

Second, patients with high microembolic load may demonstrate more extensive neuropsychological deficit involving visuospatial functions, and this right hemisphere dysfunction correlated with the intraoperative microembolic load at right middle cerebral artery in our study (Bokeriia et al., 2007; Polunina et al., 2014). It should be noted, as opposite to the major trend with higher risk of left hemisphere damage, some cardiac surgery

centers reported postoperative strokes and decreased cerebral perfusion to be more prevalent in the right hemisphere in comparison with the left one (Chernov, Efimova, Efimova, Akhmedov, & Lishmanov, 2006; Jacobs et al., 1998; Korn-Lubetzki et al., 2007). These discrepancies mean that variations in surgical and perfusion technologies may considerably influence the distribution of intraoperative microemboli within the brain circulation system and therefore the localization of brain damage.

Finally, psychomotor slowing appears to occur predominantly in elderly patients with prominent atherosclerosis, and this cognitive deficit did not correlate with microembolic load in our study (Bokeriia et al., 2007). The analysis of the data of longitudinal studies showed that psychomotor slowing is very common at 1-week follow-up, and highly reversible at 1-month follow-up in the majority of cardiac surgery patients (Bokeriia et al., 2005). This dynamics is similar to the postoperative brain swelling reversibility (Anderson et al., 1999; Bendszus et al., 2002; Harris et al., 1998), and therefore it may be suggested that postoperative psychomotor slowing is caused by disturbed conductivity and neurochemical imbalances, rather than real brain damage. Overall, psychomotor slowing is a typical neuropsychological consequence of the aging process (Swan, LaRue, Carmelli, Reed, & Fabsitz, 1992), and deficit in this cognitive domain is especially prominent in atherosclerotic patients in general population (Lopez et al., 2003; Rankin, Kochamba, Boone, Petiti, & Buckwalter, 2003).

Hence, all three cognitive domains, i.e., digit span/verbal memory, visuospatial functions and psychomotor speed should be tested perioperatively in order to register these three types of POCD. It is a common approach in research of cardiac surgery outcomes to combine tests into separate “cognitive domains,” however, to our opinion, most researchers prefer follow some imperfect psychometric tradition instead of taking neurological reality into account. Selection of optimal tests and appropriate statistical approaches are very important issues for registering subtle effects of intraoperative ischemia on brain functions in order to determine which surgical or anesthesiological technology is safer and therefore preferable.

SELECTION OF TESTS

The selection of tests remains problematic, and varies extensively between studies. Newman and colleagues (Newman et al., 2007) have counted 70 different neuropsychological tests which have been used in the studies of postoperative cognitive dysfunction, published before December 2005. Comparisons between studies are difficult because of the differences in the tests selected.

It should be noted that the ecological validity of a range of tests is also questionable. Several studies demonstrated a discrepancy between postoperative complaints in specific cognitive areas, and neuropsychological testing results (Dijkstra, & Jolles, 2002; Funder et al., 2010; Vingerhoets et al., 1995). For instance, Vingerhoets and colleagues (1995) did not find significant intergroup differences in performance on Rey Auditory Verbal Learning Test (RAVLT) between patients complaining of postoperative memory decline and patients not complaining in 1 year after surgery. And similar findings were characteristic for concentration, attention, and psychomotor speed domains in this study. At the same time, the group with cognitive complains had significantly higher anxiety and depression, as compared

to the patients without complains. Other research demonstrated that patients with greater cognitive demands had the most complaints concerning poor postoperative cognitive functioning (Funder et al., 2010).

In 1995 preliminary recommendations were given by the “Statement of Consensus on Assessment of Neurobehavioral Outcomes after Cardiac Surgery” (Murkin, Martzke, Buchan, Bentley, & Wong., 1995). The authors suggested four neuropsychological tests (Rey Auditory Verbal Learning Test, Trail Making Test parts A and B, and Grooved Pegboard test) as a core battery for research of POCD. This standard was used in many studies after 1995, and now the results of a considerable proportion of neuropsychological studies in the cardiac surgery field may be compared and analyzed.

In our analysis of 24 publications concerning neuropsychological outcomes of cardiac surgery (Polunina, 2008) we found that studies which used a test battery recommended by Statement of Consensus on Assessment of Neurobehavioral Outcomes after Cardiac Surgery (i.e., RAVLT, TMT A and B, and Pegboard test), showed significantly lower incidence of POCD after 1-3 months of follow-up, as compared to the studies which used Digit Span and Non-verbal memory tests (average incidence: 28 - 32% versus 45 - 52%). These data evidence, that selection of tests may considerably influence the findings in cardiac surgery outcome studies.

In our study (Polunina et al., 2014), we found that tests measuring auditory span were more sensitive to postoperative cognitive deficit, compared to word, or story learning. Moreover, in the same cohort of young patients after open heart operations, we found a strong correlation between postoperative changes of the performance on Digit Span Forward, and intraoperative microembolic load at left middle cerebral artery, whereas the correlation between postoperative changes of word list learning and microemboli only showed the same trend (Bokeriia et al., 2007). In CABG patients, we observed significant correlation between the length of cardiopulmonary bypass, and postoperative changes of performance on the Digit Span Forward, but not on word-learning or story-learning tests.

The similar results showed the analysis of literature data (Polunina, 2008), i.e., studies, which used Digit Span, demonstrated significantly higher POCD incidence, compared to studies which did not use Digit Span (mean POCD incidence: $45.7 \pm 23.3\%$ vs $26.2 \pm 18.0\%$, $t = 2.63$, $p = .013$). At the same time, studies which used RAVLT (word list learning), reported lower POCD incidence, compared to studies which did not use RAVLT (mean POCD incidence: $32.8 \pm 21.0\%$ vs $47.7 \pm 25.1\%$, $t = 1.81$, $p = .08$). Overall, Digit Span appears to represent neurological reality more efficiently in the context of the postoperative cognitive dysfunction, when compared to word-learning, or story-learning test paradigms. Although Digit Span is commonly referred to as an “attention span” test, whereas word list learning tests are considered to relate to “verbal memory” domain, both of these tests appear to be supported by normal functioning of left temporal cortical structures, and therefore are sensitive to the similar neurological functions.

In addition, we observed significant linear correlations between microembolic load at right middle cerebral artery and postoperative decline of the performance on Benton Visual Retention Test ($R = -0.39$, $p = 0.018$) and overall microembolic load and postoperative deficit in Block Design test ($R = -0.31$, $p = 0.04$) in the cohort of patients after open heart surgery (Polunina et al., 2014). This postoperative cognitive deficit was not typical for CABG cohort, and no correlations between visuospatial tests and microembolic load in this group were

found. It should be noted, that open heart operations were characterized by almost twice as large microembolic load at right MCA compared to the CABG group; therefore, a deficit of right hemisphere functions was related to a larger microembolic load to this brain structure in open heart patients.

Finally, in our study (Polunina et al., 2014) both patient groups showed post-operative slowing of performance on timed tests (i.e., Digit Symbol and TMT, parts A and B), and intraoperative microembolic load did not correlate with performance on timed tests. At the same time, there was a significant association between an older age and the slowing of psychomotor speed at the baseline and post-operative follow-up, i.e., this function was especially sensitive to the effects of ‘on-pump’ in elderly patients.

Analysis of literature data showed that 13 studies which used Pegboard test, for assessment of POCD during first week after cardiac surgery, found significant impairment of performance in the studied patient cohorts, whereas only 4 of 20 (5%) studies reported the same trend at their 1 – 3 month follow-up (Bokeriia et al., 2005). Very similar dynamics was characteristic of TMT A and B, Digit Symbol, Reaction time tasks, Letter-Cancellation, and Stroop test, (i.e., neuropsychological probes with high loading on psychomotor speed processes). Hence, psychomotor speed tends to normalize during first weeks after operations.

It should be stressed, that the battery of 10 tests was difficult to perform for patients at early postoperative follow-up in our first study, and therefore we used only 5 tests for the assessment of POCD in our second study. Digit Span and Block Design were easier to perform for our patients in comparison with word list learning test or Benton Visual Retention Test, therefore we had chosen these tools. Digit Symbol was chosen as a measure of psychomotor speed, as this test is well known and therefore more popular in Russia in comparison with TMT or Pegboard. Finally, we also included MMSE, as it proved to be an effective tool for measuring postoperative changes of global cognitive status. Overall, we found the same three types of POCS in the second study (Polunina et al., 2014). At the same time, the dropout rate among cardiac surgery patients was considerably lower in our second study in comparison with the first one.

Computerized tests appear to be more sensitive and precise for POCD diagnostics in comparison with conventional tests, and are preferable for studies in this field (Silbert et al., 2004). However, availability of computerized tests remains lower in comparison with conventional ones, and therefore the latter are more frequently used especially in medical centers with low research budget. Still, computerized battery of tests for POCD diagnostics should contain tests sensitive to three types of POCD, i.e., left hemisphere dysfunction (digit span), right hemisphere dysfunction (visuospatial functions), and easy motor and perceptual tests measuring psychomotor speed/reaction time.

LIMITATIONS OF PSYCHOMETRIC TESTING IN POCD STUDIES

It is an established fact that repeated neuropsychological evaluations lead to changes in performance, independent of any changes in underlying function or capacity, due to practice effect or regression to the mean phenomenon (Browne, Halligan, Wade, & Taggart, 1999; Collie et al., 2002; Funder et al., 2010; Rasmussen et al., 2001; Slade et al., 2001; 50-52).

The statistical phenomenon of 'regression to the mean' may considerably influence the results of studies of cardiac surgery outcomes (Browne et al., 1999), and it means that normal subjects with the lower performance at the first assessment would increase their results at the follow-up, whereas subjects with higher performance would decrease their results at repeated assessment, showing the trend to reach group means. The phenomenon 'regression to the mean' in cardiac surgery outcome research was demonstrated by Browne and colleagues (1999). In their study, authors observed significant decline of group mean score on delayed recall in Rey Auditory Verbal Learning Test (RAVLT) and significant improvement (practice effect) on the Trail Making Test part A (TMT A) score at three month follow-up after surgery. However, when subjects were divided into 3 baseline performance category (low, moderate and high), only high performers showed significant deterioration on RAVLT, whereas only low performers showed significant improvement (practice effect) on TMT A at 3 months follow-up. Moreover, high performers also slightly but significantly deteriorated on TMT A. Authors concluded, that the use of group mean data with appropriate control group mean data should be the method of choice in cardiac surgery research, as the phenomenon of regression toward the mean precludes dichotomous approach (impaired/non-impaired) to the analyses of cardiac surgery effects on cognitive functions.

Two other research groups also demonstrated prominent effects of preoperative cognitive performance on magnitude and direction of postoperative changes. In the study of Robson et al. (2000) baseline performance on all cognitive tests accounted for 47-82% of variance of postoperative changes, whereas aortic atheroma explained only 1-5% of independent variance of postoperative changes in four from seven cognitive scores. Newman et al. (2001a) reported significant association between baseline cognitive performance and postoperative changes of cognitive index in five years after surgery with considerably greater "impairment" signs in patients with high preoperative performance. Hence, phenomenon of regression to the mean represents very strong and consistently demonstrated trends in cardiac surgery outcome research and should not be ignored.

The magnitude of the practice effect considerably varies across the tests and patient cohorts. As it was already discussed, the practice effect during repeated neuropsychological evaluations is most prominent in low baseline performers (Browne et al., 1999). In addition, we registered the significant effect of a position of a test within a test battery on the study results. Practice effect at the follow-up assessment was most prominent when a test was administered at the beginning of testing (Polunina et al., 2014).

Another serious limitation of neuropsychological studies of surgery outcomes is the lower baseline cognitive performance in patient groups in comparison with controls. For instance, it was consistently shown that heart disease is a risk factor for dementia and cognitive dysfunction (Justin, Turek, & Hakim, 2013), and therefore matching healthy control subjects is very problematic. Also when effects of perioperative factors are studied, it is not uncommon that patients with more severe perioperative conditions are characterized by more prominent preoperative cognitive dysfunction in comparison with healthier controls, and the same is true for lost to follow-up patient cohorts in comparison with those, who were included in the studies (Funder et al., 2010; Puskas et al., 2007; Selnes & Gottesman, 2010). Hence, matching groups according to age and sex does not help to eliminate intergroup differences in baseline cognitive functioning in studies comparing cardiac surgery patients and normal controls.

Previously analyses of group means in cardiac surgery outcome research were criticized because "a group mean score reflects both the individuals whose performance is compromised due to POCD and those whose performance is enhanced as a consequence of practice; accordingly the net result may be no significant group differences from baseline score" (Murkin, J.M., Stump, D.A., Blumenthal, J.A., McKhann, G., 1997). At present several studies showed, that inclusion of a control group into a study protocol allows easily to overcome this problem (Keith et al., 2002a; Lee et al., 2003; Nagels et al., 2004). Moreover, in two studies the cardiac surgery group demonstrated absence of practice effect on memory tests in comparison with a control group, and these findings clearly indicated postoperative cognitive deficits, which might be overlooked in the absence of controls (Keith et al., 2002a; Lee et al., 2003).

DICHOTOMOUS CRITERIA OF POCD

The majority of studies of POCD have dichotomized cognitive outcome after surgery, classifying patients as "impaired" or "unimpaired" on the basis of their baseline cognitive performance. Multiple dichotomous criteria of POCD (impaired vs not impaired) were widely used in research of cardiac surgery outcomes. These included: 20% drop criterion in at least 1, 2 or more tests or cognitive domains (postoperative decline in test scores by at least 20% from baseline); 0.5 SD, 1 SD, 1.5 SD, 2 SD or 3 SD criterion of decline in at least 1, 2 or more tests or cognitive domains (SD – standard deviation); reliable change indexes (RCI); impairment in comparison to normative index in at least 1, 2 or more tests or cognitive domains; 1SD or 20% decline of composite z-score; decline of $z\text{-score} > 1.96$ in 1 or 2 cognitive tests; 10% drop criterion in 1 or 2 tests or cognitive domains; 5 percentile decline in at least 1 or 2 cognitive domains; any decline in 1 or 2 tests; etc. The most commonly used techniques in studies of POCD are 1SD and 20% decline criteria.

Several studies compared the incidence of POCD according to different dichotomous criteria, and showed, that the incidence of "impaired" cases considerably varies when different criteria of POCD are applied (Browne et al., 1999; Bruggemans, Van de Vijver, & Huysmans, 1997; Kneebone et al., 1998; Mahanna et al., 1996; Raymond, Hinton-Bayre, Radel, Ray, & Marsh, 2006). It is obvious, that criterion of 0.5 SD would always classify more cases as impaired ones in comparison with 1 SD criterion, whereas 1 SD criterion would classify considerably more cases as POCD-positive in comparison with 1.5 SD, 2 SD or 3 SD criteria. The same trend is also true for the criteria defining POCD as decline in at least 1, 2, 3 or more tests.

Mahanna and colleagues (1996) used five different criteria to define neuropsychological deficits after cardiac surgery and found a sixfold difference in the incidence of deficits (3.4-19.4%). The authors showed that 20% drop criteria identified the largest proportion of patients with cognitive deficits in comparison with other three criteria of POCD. For instance, 34% patients exhibited cognitive deficit due to 20% drop criterion, whereas only 13.8% patients were classified as "impaired" by 1 SD criterion in 6 weeks after surgery. Similar trends were consistently found in the analyses of pre-discharge and 6 month follow-up data. Browne et al. (1999) also reported considerably larger incidence of decline on RAVLT or TMT A when 20% criterion was applied in comparison with 1 SD criterion both at pre-

discharge and 3 month follow-up. Rasmussen et al. (2001) also confirmed these findings by their data. Hence, at least three research groups found 20% decline criterion to be considerably less stringent in comparison with 1 SD criterion.

Important, that in the study of Mahanna and colleagues (1996) there was little agreement among the four measures of cognitive impairment tested in that study. Only 2.8% of the sample was rated as impaired by all four criteria and only 31.5% was consistently rated as non-impaired. The authors criticized the 1 SD criterion, because this method cannot show cognitive decline if a patient's baseline score is too low, and this was the reason why up to one third of the sample of Mahanna and colleagues (1996) was misclassified by 1 SD criterion.

More sophisticated dichotomous approaches were suggested for overcoming practice effect and regression to the mean during repeated neuropsychological evaluations (Bruggemans et al., 1997; Collie et al., 2002; Kneebone et al., 1998; Rasmussen et al., 2001; Raymond et al., 2006). The reliable change indexes (RCI) which provide criteria for meaningful change based on the calculated measurement error for each score. A patient's predicted retest score equals their pre-operative score plus mean practice effect detected in a matched control group. If the difference between the actual and expected retest score exceeds the likely variation based on matched controls, a significant change is considered to have occurred (Raymond et al., 2006).

Considerable discrepancies in case classification by 1 SD and reliable change indexes were reported as well (Bruggemans et al., 1997; Kneebone et al., 1998). In the study of Kneebone and colleagues (1998) RCI classified more patients as showing a postoperative decline in 7 of 11 neuropsychologic tests in comparison with the 1 SD method. At the same time, 1 SD criterion classified more patients as showing decline on California Verbal Learning Test in comparison with RCI.

The Standardized Regression-based technique (SRB) generates a regression equation to predict a patient's score change on the bases of preoperative performance, plus any demographic variables that contribute significantly to the prediction model in matched controls (Raymond et al., 2006). The expected change is therefore dependent on initial performance rather than mean practice effect. Raymond and colleagues (2006) compared RCI, SRB, 20% and 1 SD criteria in their study of outcomes of cardiac surgery. Patients were classified as impaired if they demonstrated deterioration on 2 or more of the nine test scores used. The SRB and RCI techniques classified more patients as declined than the SD or 20% methods on all scores of MicroCog except reaction time. The average incidence of decline across scores was 3.6% (SD method) and 4.2% (20% method), compared to 7.7% (RCI method) and 13.3% (SRB method).

Although RCI and SRB procedures seem to be logical in eliminating practice effect and regression to the mean effect, some authors argued that unlike strokes POCD is not a dichotomous event but occurs along a continuum (Keith & Puente, 2002b; Selnes & Gottesman, 2010). Moreover, the practice effect may be smaller in patients due to preoperative mild cognitive dysfunction in comparison with healthy subjects, whereas mean group practice effect of healthy controls instead of individual practice effects is calculated for RCI (Keith & Puente, 2002b; Newman et al., 2007).

The number of tests in a test battery and whether they were drawn from separate domains may also contribute to the magnitude of POCD incidence, when the definition of POCD involves a deterioration on a specified number of tests. We analyzed the data of 24

publications, which included 34 patient cohorts (Polunina, 2008), and the number of tests varied from 1 to 15 in these studies. We found that the magnitude of POCD incidence positively correlated with the total number of neuropsychological tests and the number of timed tests used in a study ($R_s=.38$ and $.36$, $p=.03$ and $.04$), however, only when patients were tested during the first postoperative week. The incidence of POCD at more delayed follow-up (1 - 3 months) did not correlate with the total number of neuropsychological tests used in a study ($R=-.07$, $p=.65$) and negatively correlated with the number of timed tests ($R=-.41$, $p=.006$). At the same time, strong correlations were found between the incidence of delayed POCD and the number of memory tests and/or the number of visuospatial tests ($R_s=.62$ and $.69$, $p_s=.000$).

Hence, the dichotomous methods are far from being perfect for POCD studies. Methods taking into account practice effect and regression to the mean effects tend to show larger incidence of POCD in comparison with fixed criteria (1SD, 20%, etc.). The number and quality of tests in the test battery may significantly influence the results of studies of neurological outcomes of cardiac surgery.

Z-SCORES, FACTOR ANALYSIS AND RAW SCORES

Z-scores are expressed in terms of standard deviations from their means, and therefore z-scores have a distribution with a mean of 0 and a standard deviation of 1. In research of POCD, z-scores are commonly used when scores of several tests are summarized into a cognitive domain or a composite cognitive index. However, some authors convert raw scores into z-scores in order to determine changes of performance on individual tests or even to compare group means at preoperative testing and at follow-up (e.g., Hernandez et al., 2007). To our opinion, using z-scores instead of raw scores may contribute to inconsistencies in the results of studies of surgery outcomes. For instance, one of the studies compared mean z-scores of on-pump and off-pump coronary surgery patients and found somewhat worse outcomes in off-pump patients in comparison with on-pump ones at 6 month follow-up (Hernandez et al., 2007), whereas the general trend is opposite (Sun, Wu, Wang, & Jin, 2012).

Here we demonstrate the results of retrospective analysis of our data, which were presented in detail elsewhere (Bokeriia et al., 2007; Polunina et al., 2014), in order to show obvious discrepancies between the results of the analysis of raw and z-score data. The statistical coefficients are summarized in Table 1, and the dynamics of performance on three tests at 2-week follow-up is presented in Figures 1 – 3.

Overall, the intergroup differences in changes of raw and z-scores were similar in all analyses of variance. However, when the magnitude of change was calculated for each patient group separately, the results of statistical analyses differed considerably for Digit Span Forward and Benton Visual Retention Test.

The group means of Digit Span Forward raw scores declined significantly after both coronary and open heart surgeries, however, group means of z-scores did not show significant changes when the data of controls were either included into or excluded from the calculation of z-scores (Figure 1, Table 1). Both patient groups showed these negative effects of using z-scores instead of raw scores for defining postoperative changes of performance on Digit Span

Forward, and this trend was especially obvious for analyses of the data of the patient groups without controls. It should be stressed, that comparisons of patient groups are highly important when effects and safety of surgical technologies are evaluated.

Table 1. ANOVAs and paired t-tests of raw and z-scores, which were calculated with and without inclusion of the data of the healthy controls*

Test scores	Time/Group interaction with Controls	Time/Group interaction without Controls	Change after CABG (n=29)	Change after Open Heart (n=36)
Digit Span Forward				
raw scores	$F_{2,74}=11.7$, $P<0.001$	$F_{1,63}=0.46$, $P=0.830$	$t=3.52$, $p=0.001$	$t=3.84$, $p<0.001$
z-scores with Controls	$F_{2,74}=12.8$, $P<0.001$	$F_{1,63}=0.08$, $P=0.775$	$t=1.58$, $p=0.125$	$t=1.36$, $p=0.183$
z-scores without Controls	-	$F_{1,63}=0.11$, $P=0.746$	$t=0.36$, $p=0.721$	$t=-0.09$, $p=0.930$
Benton Visual Retention Test				
raw scores	$F_{2,72}=4.77$, $P=0.011$	$F_{1,63}=3.70$, $P=0.059$	$t=0.76$, $p=0.456$	$t=4.59$, $p<0.001$
z-scores with Controls	$F_{2,72}=4.39$, $P=0.016$	$F_{1,63}=3.72$, $P=0.058$	$t=-0.66$, $p=0.515$	$t=2.40$, $p=0.022$
z-scores without Controls	-	$F_{1,61}=3.67$, $P=0.060$	$t=-1.13$, $p=0.268$	$t=1.63$, $p=0.112$
Digit Symbol				
raw scores	$F_{2,74}=30.9$, $P<0.001$	$F_{1,63}=10.2$, $P=0.002$	$t=2.69$, $p=0.012$	$t=-1.49$, $p=0.146$
z-scores with Controls	$F_{2,74}=24.8$, $P<0.001$	$F_{1,63}=9.32$, $P=0.003$	$t=3.65$, $p=0.001$	$t=0.18$, $p=0.858$
z-scores without Controls	-	$F_{1,63}=10.2$, $P=0.002$	$t=2.36$, $p=0.026$	$t=-2.02$, $p=0.052$

Abbreviation: CABG, coronary artery bypass grafting;

* Paired t-tests were calculated for each of two patient groups separately.

The similar trend characterized the dynamics of raw and z-scores on Benton Visual Retention test in patient cohort, which underwent open heart operations (Figure 2, Table 1). This patient group demonstrated significant decline of group mean raw score on Benton test in 2 weeks after surgery, and this trend was robust ($t=4.59$, $p<0.001$). Analysis of z-scores, which included controls, also showed significant differences between patient cohorts, but this trend was somewhat weaker ($t=2.40$, $p=0.022$). Finally, analysis of z-scores, which included only patients, did not demonstrate significant intergroup differences in perioperative dynamics of z-scores in two patient groups.

Interestingly, the patients after open heart operations did not demonstrate any real change of raw score on Digit Symbol test at postoperative follow-up. Nevertheless, analysis of z-scores derived in total patient cohort without controls showed significant improvement of patients after open heart operations due to real worsening of means of raw and z-scores in the cohort of patients after coronary surgeries.

Figure 1. Changes of performance on Digit Span Forward test in patients after coronary surgery (n=29), patients after open heart operations (n=36) and healthy controls (n=12).

Figure 2. Changes of performance on Benton Visual Retention Test in patients after coronary surgery (n=29), patients after open heart operations (n=36) and healthy controls (n=12).

Figure 3. Changes of performance on Digit Symbol in patients after coronary surgery (CABG; n=29), patients after Open Heart operations (n=36) and healthy controls (n=12).

Overall, these data evidence, that z-scores should be used cautiously in research of subtle changes of cognitive functions. And analysis of z-scores should be performed as an additional option with obligatory comparison of its results with the results of analysis of raw neuropsychological scores.

Factor analysis is rarely used in research of cardiac surgery outcomes, however, some studies which used factor analysis are very influential and highly cited (Newman et al., 2001a; 2001b). The authors argued that each test loaded on each factor consistently at baseline and follow-up assessments, and therefore the cognitive domains also remained consistent throughout follow-ups in their study, which included 4 follow-ups (before discharge, in 6 weeks, 6 months and 5 years after surgery).

In our study (Polunina et al., 2014) we did not observe the consistency of the factor analysis results of preoperative and postoperative data (Table 2) perhaps due to lower number of subjects and inclusion of the controls into the analysis. However, if the term ‘cognitive domain’ relates to any objective reality then it may be expected that this entity would not be changed by inclusion of any category of subjects, especially normal controls, into the analysis.

Most important that key tests loaded differently on two factors, which were derived from preoperative and postoperative data. Both parts of Digit Span strongly loaded on the second factor, which explained 14.3% of neuropsychological variables at preoperative period. However, postoperative results of Digit Span Forward loaded predominantly on the first factor, whereas Digit Span Backward weakly loaded on two factors derived from postoperative data. Loadings of Digit Symbol distributed also differently at baseline and at postoperative follow-up. Nevertheless, the results of Word list learning test, Block Design test, Benton Visual Retention Test and some other tests demonstrated similar loading on two factors at both assessments.

Table 2. Factor analysis of neuropsychological variables at preoperative and postoperative assessments in the combined subject group (patients + controls, n=75)[#]

Neuropsychological variables	<i>Preoperative period</i>		<i>Postoperative period</i>	
	<i>Factor I</i>	<i>Factor II</i>	<i>Factor I</i>	<i>Factor II</i>
% of variance	41.0%	14.3%	51.3%	11.0%
Digit Symbol	0.508*	0.585*	0.784*	0.173
TMT A	-0.260*	-0.686*	-0.179	-0.852*
TMT B	0.097	-0.703*	-0.127	-0.821*
Benton Visual Retention Test	0.509*	0.285*	0.689*	0.209
Digit Span Forward	0.274*	0.711*	0.762*	0.342*
Digit Span Backward	0.356*	0.794*	0.575*	0.541*
MMSE	0.774*	0.189	0.724*	0.291*
Block Design test	0.664*	0.383*	0.629*	0.389*
Word list learning test	0.772*	0.056	0.772*	0.012
Logical memory test	0.756*	0.028	0.784*	0.162

* Significant Pearson's correlations between neuropsychological variables and extracted factors, $P < 0.05$.

[#] The factor analysis of neuropsychological variables was conducted using principle component method, with varimax rotation.

These data evidence, that z-scores and factor analysis should be used cautiously in research of subtle changes of cognitive functions. And these mathematical methods should be performed as an additional option after obligatory analysis of raw scores is completed.

CONCLUSION

Studies of the associations between distribution of intraoperative microemboli in the cerebral circulation and postoperative cognitive changes showed that at least three types of POCD may be outlined, i.e., left hemisphere dysfunction with decline of digit span/verbal learning, right hemisphere dysfunction with decline of visuospatial processing and diffuse psychomotor slowing, which is most prominent in elderly atherosclerotic patients. Accordingly, tests sensitive to all these cognitive domains should be included into the test batteries in studies of POCD. Analysis of our data and the literature showed that short-term memory span tests (Digit Span Forward and Backward) are more effective, compared to word-learning and story-learning tests as a tool for registration of postoperative cognitive dysfunction. Non-verbal memory span tests may be recommended for future studies as a tool for evaluation of right hemisphere functions. Finally, a psychomotor speed test (e.g., Digit Symbol) should be included into test batteries, as a tool for evaluation of POCD, which is characteristic for early postoperative period and aging process. It is important to take into account, that administration of a test in the beginning of testing may increase practice effect at the follow-up assessment.

The limitations of psychometric testing as a method of POCD definition include the lower baseline performance in cardiologic patients in comparison with matched healthy controls, the regression to the mean phenomenon and practice effects. Although the majority of studies of POCD have dichotomized cognitive outcome after surgery, classifying patients as “impaired” or “unimpaired,” this approach has a range of serious limitations, leading to discrepancies in case classification by different dichotomous criteria. Conventional separate repeated measures ANOVAs on each raw score of cognitive variables with inclusion of control group is highly preferable. Whereas dichotomous criteria of POCD, z-scores and factorization of scores may be used as additional options, and the results of these analyses should be interpreted cautiously.

CONFLICT OF INTEREST

The authors declare that they have no conflict of interest.

ABSTRACT

Strabismus is caused by the misalignment of extraocular muscles, and produces loss of binocular vision and amblyopia. This pathology can be inherited, developed or acquired, and can be associated with several comorbidities (neuromuscular diseases, congenital syndromes or cardiac diseases). Thus a suitable pre-anesthetic evaluation is important to assess each patient's individual requirements and their impact on perioperative morbidity.

Strabismus is the most frequent ocular surgery performed in childhood. This surgery aims to restore ocular alignment to maintain visual acuity, achieve a favorable esthetic result, improve depth perception, and to eliminate double vision, if present. This surgery also requires having to achieve anesthesia that provides akinesia, analgesia, and sometimes ocular hypotonia, to adjust sutures.

Strabismus surgery is characterized by being done in an outpatient setting. It implies the usual intraoperative and postoperative complications, which must be known to avoid them by prophylactic measures. The commonest complications are oculocardiac reflex, nausea, and vomiting and postoperative pain. Several studies have assessed the effectiveness of different drugs and anesthetic techniques, and the prophylactic measures to reduce these complications.

The different anesthetic techniques used include general anesthesia, retrobulbar anesthesia, peribulbar anesthesia, sub-Tenon's anesthesia, or a combination of sedation/topical anesthesia, sedation/peribulbar anesthesia and sedation/local anesthesia.

* Corresponding Author's Email: monicadelriov@hotmail.com.

† Corresponding Author's Email: josegarciam@yahoo.com.

Each anesthetic technique offers several advantages and disadvantages, which are assessed in each case to choose the most suitable technique in each patient. Moreover, adequate surgeon experience in the technique is essential, as is suitable patient cooperation during the procedure.

INTRODUCTION

Strabismus is an ocular misalignment that produces loss of binocular vision and amblyopia (vision loss in a structurally normal eye) [1]. It is a relatively frequent pathology that can affect up to 3% of the general population. Its incidence in children lies between 2-7%, with an age prevalence of 2-4 years [1-5].

This pathology can be inherited, developmental or acquired, or may be associated with neuromuscular diseases. Children with strabismus or palpebral ptosis could either be at higher risk of malignant hyperthermia or related with any undiagnosed cardiomyopathy. So preanesthesia is required in these patients [6, 7]. It is the most frequently performed surgery in the pediatric population, and is usually done in outpatient settings [8].

The aims of surgery are to restore ocular alignment to maintain visual acuity (no amblyopia), provide cosmetic correction (orthotropia), confer depth perception (stereopsis), and eliminate double vision [3-5]. Visual maturation happens around the age of 5, so it is important to repair strabismus early in childhood [5].

This surgery can have side effects during intraoperative and postoperative management. One of the main problems associated with strabismus surgery is oculocardiac reflex (OCR), which appears more frequently in children due to a relative increase in vagal tone [9]. There are no data available about a precise OCR incidence estimates in adult strabismus surgery because the definition of OCR is not the same for all authors. Besides, most studies are based on data taken from pediatric populations [9]. OCR can be defined as a trigeminal vagal reflex that produces bradycardia, hypotension, dysrhythmias or sinoatrial arrest, associated with ocular muscle traction [10-13]. OCR is associated with postoperative nausea and vomiting (PONV) from stimulating the oculometric reflex, with an incidence of 46-85% [14-16]. Several maneuvers have been studied to reduce OCR (preventing hypoxemia and hypercapnia, premedication with atropine or glycopyrrolate, and adequate anesthetic depth). However, no maneuver has proven effective, safe or acceptable [8, 15-17]. Treatment using atropine may cause a variety of cardiac arrhythmias [18].

Other side effects of this surgery include pain and PONV. PONV has an incidence of around 88% in these patients when they are not treated [19]. Postoperative PONV also depends on the anesthetic technique used, postoperative pain management and antiemetic therapy. Thus suitable knowledge and control of these factors by an anesthesiologist will enable safe and cost-effective anesthesia to be performed with quick awakening and minimal incidence of pain, nausea and vomiting.

ANESTHETIC MANAGEMENT

There are several anesthetic techniques for strabismus surgery: general anesthesia, regional anesthesia (peribulbar anesthesia, retrobulbar anesthesia and sub-Tenon's block) and topical anesthesia.

The necessary fasting for surgery and parenteral separation lead to a period of perioperative anxiety in children. Suitable preoperative hydration reduces the incidences of intraoperative hypoglycemia and hypovolemia, and PONV. It is advisable to freely drink clear iv liquids until 2-3 hours preoperatively with iv crystalloids to lower PONV [4, 20]. In fact one published study recommends administering liquids at 30 mL/kg/h instead of at 10 mL/kg/h [21].

Perioperative anxiety can be managed with anxiolytics. In pediatric patients, ansiolysis is often administered from a protocol point of view after 18 months. There are several drugs used for premedication (e.g., oral midazolam). Another option is to allow parents to enter the operating room until anesthetic induction.

General Anesthesia

As immobilizing patients during strabismus surgery is important to avoid complications, general anesthesia is the anesthetic technique of choice in pediatric ocular surgery.

Both inhalation general anesthesia and intravenous general anesthesia have been used successfully in strabismus surgery. The most widely used inhalation anesthetics are sevoflurane, isoflurane or desflurane in air and oxygen. Desflurane offers a low blood/gas ratio, thus it allows quick anesthetic induction. However, this inhalation anesthetic has been associated with greater airway irritability when used in induction, so its use is more extended to maintain anesthesia. Nitrous oxide could increase perioperative nausea or vomiting, but this relation remains controversial [20, 22]. Sevoflurane seems to produce lower OCR incidence than propofol because this anesthetic depresses vagal activity. Hence it produces less bradycardia when manipulating extraocular muscles (EOM), along with a lower incidence of dysrhythmias in children compared with halothane [23, 24].

Propofol is an intravenous anesthetic of choice for strabismus surgery in older pediatric patients. It is an isopropyl phenol with quick onset and end of action. It does not produce analgesia, but generates minimum residual sedation and is a powerful antiemetic. However, if this drug is used only in induction and it is not used in anesthesia maintenance, no effect to diminish PONV is observed [25]. PONV lowers if used in anesthesia maintenance, but this can result in higher OCR incidence compared with other anesthetics [2, 12, 22, 26, 27].

Another intravenous anesthetic is ketamine. This drug is associated with fewer hemodynamic changes for strabismus surgery in pediatric patients [28], probably due to different mechanisms, which include the antagonism effect in N-methyl-D-aspartate receptors [29, 30], intrinsic analgesia and amnesic properties that protect the airway reflex [31, 32]. It has an analgesic effect at subanesthetic doses [30]. If low doses of this drug are used, thalamic sensory output and arousal increase [33], and duration is relatively quick-acting and short. Ketamina could avoid vagal stimulus, and could protect against parasympathetic activity that induces OCR in patients who are more prone to develop it. So iv ketamine administration seems safe and useful for monitoring anesthesia care in outpatient settings [34].

Regarding neuromuscular relaxants, as surgery lasts 30-60 minutes, it is advisable to use neuromuscular relaxants that offer intermediate action, such as atracurium or rocuronium. One of the beneficial effects of rocuronium in such surgery is the vagolytic effect described in a published study, hence OCR incidence lowers if it is used at low doses [34]. Neuromuscular

relaxants, except for succinylcholine, reduce intraocular pressure (PIO) by relaxing EOM, which is something that we must bear in mind if strabismus surgery is accompanied by tonometry.

We can either perform endotracheal intubation or insert a laryngeal mask airway. Endotracheal intubation requires deeper anesthesia, increases PIO and results in a higher incidence of respiratory events during the postoperative period.

The effect of general anesthesia on EOM tone is that it can hinder ophthalmologists' ability to ensure the ocular position and to gauge the extent of any necessary correction [35].

Regional Anesthesia

Although general anesthesia remains the most widely used anesthetic technique in strabismus surgery, more and more ophthalmologists perform this surgery with regional anesthesia in adult patients. It is also one of the more painful ophthalmological surgery types that can benefit from the postoperative analgesia offered by this kind of anesthesia. Furthermore, it enables us to explore and correct surgery results with awake patients before surgery ends [36].

Regional anesthesia is used with general anesthesia in children. Several studies have confirmed that using preoperative regional blocks avoids having to resort to intraoperative anesthetics and opioids, contributes to postoperative analgesia, and allows faster recovery, which is important in outpatient surgery [37-40]. Moreover, a drop in OCR incidence has been observed due to the sensitive block of afferent pathways, as well as a drop in PONV, which is the commonest complication in strabismus surgery [28, 41].

In order to successfully perform strabismus surgery under regional anesthesia, working with a surgeon who is sufficiently competent in the anesthetic technique is essential, as is suitable patient contribution during the procedure [36].

Several types of regional anesthesia are used in ocular surgery: peribulbar, retrobulbar, and sub-Tenon's blocks.

Peribulbar and Retrobulbar Anesthesias

Peribulbar anesthesia is performed to inject the anesthetic drug (6-8 ml) into the orbit around the equatorial line of the eyeball. Retrobulbar anesthesia is performed to inject anesthetic drug (3-4 ml) into the orbit, and even further behind the eyeball, where nerves manage eye movement and sensitivity.

Both anesthetic techniques incur the risk of producing major complications, such as the intravenous or subarachnoid injection of local anesthetic, or ocular complications such as perforating the eyeball, optic nerve damage and retrobulbar bleeding, with possible loss of vision [42-45].

Moreover, anesthetic techniques produce anatomical distortion and akinesia if large volumes of local anesthetics are injected into the orbital space, which implies problems to properly fit ocular alignment. Other complications are miotoxicity by local anesthetic as it can produce fibrosis or muscular hypertrophy [46].

Peribulbar anesthesia, compared with retrobulbar anesthesia, requires a large volume of local anesthetic, but peribulbar anesthesia complications are minor because the needle used is shorter [47].

Sub-Tenon's Block

This anesthetic technique offers similar conditions for anesthesia and ocular akinesia to peribulbar anesthesia, but has a lower major complication rate and produces less pain when applied [48-50]. However, some patients have complained about conjunctival incision or Tenon's capsule and EOM traction [51]. The commonest complication is subconjunctival bleeding, although the same peribulbar anesthesia complications have also been described with this technique [52].

It is done with local anesthetics, which are injected into the back Tenon's capsule. The analgesic effect of sub-Tenon's anaesthesia is apparently due to the blockage of ciliary ganglia and short posterior nerves to the EOM [53]. As this regional anesthetic technique is performed under direct vision, it provides a safe effective anesthesia and entails a minimal risk of serious complications [54, 55].

This technique is a safe method to reduce PONV, postoperative pain, and to provide better adult patient satisfaction compared to general anesthesia [53]. It also allows faster hospital discharge [56]. Its effectiveness to reduce OCR is controversial. Some studies have observed a lower incidence of OCR, and therefore of PONV [57], but other studies have not observed this effect [58].

Sub-Tenon's block allows eyes to be aligned according to patient satisfaction at the time of surgery [51]. This anesthetic technique, compared with topical anesthesia, allows more patient and surgeon comfort.

Topical Anesthesia

It is a non invasive technique with very few adverse effects and allows effective anesthesia on the ocular surface. Insertion of needles, which happens in regional anesthesia, is avoided by this anesthetic technique and general anesthesia is also avoided.

Many studies about successful topical anesthesia in strabismus surgery for adults have been published, while most studies supplement the technique with sedation, which is either intravenous hypnotic or opioid, and have been used to avoid potential patient discomfort with muscular traction or conjunctiva manipulation [36].

Despite usually being a well-tolerated anesthetic technique, cases of discomfort have been described with dissection and manipulation of rectus muscles. This can be avoided if muscles are carefully manipulated, or combined with greater sedation or local anesthetic administration. If local anesthetic is managed in gel, it can increase its penetration [59-64].

Given the stress that this anesthetic technique produces in surgeons, the recommendation is that surgeons have sufficient experience in EOM surgery before they apply it [62].

Lack of akinesia and patient collaboration allow ocular alignment to be more accurately fitted and the incidence of reoperation lowers [60, 61, 63-65]. A lower OCR incidence has been observed [60, 61, 64, 66].

Contact topical anesthesia is a variant of traditional topical anesthesia with drops. It allows greater local anesthetic penetration on the ocular surface after applying a gelatin sponge soaked with local anesthetic. This anesthetic technique provides a more comfortable and deeper anesthesia [36], although it is true that some patients feel uncomfortable with muscular traction [9]. As with traditional topical anesthesia, lack of akinesia allows better suture adjustment. Although some studies have been published that report lower incidences

for PONV and OCR, and good pain control [9], more research is needed to assess these points. Besides, this technique needs to be compared with all the other techniques used in strabismus surgery [36].

Suitable patient monitoring by anesthesiologists is advisable to assess good pain control and the possible appearance of side effects, plus the safety matter of being able to convert to general anesthesia if any complication occurs [62].

PREVENTING AND TREATING POSTOPERATIVE PAIN

Excessive postoperative pain produces nausea, distress and delays patients being discharged from recovery rooms. Preventing and treating postoperative pain in strabismus surgery is a challenge for anesthesiologists. Pain that occurs after strabismus surgery comes from the conjunctival area, Tenon's capsule, sclera and stretched muscles [57]. Different regional anesthesia techniques, combined with general anesthesia, have contributed to reduce postoperative pain.

Opioids are drugs that are often used in strabismus surgery, but must be used very carefully because they produce nausea and vomiting, which could cause respiratory depression by excessive sedation and could delay patient discharge [67].

Some studies report good pain control without using opioids, such as ibuprofen or ketorolac, and even indicate a similar degree of effectiveness to morphine and pethidine, but with low PONV incidence [68-70]. Ketorolac has been demonstrated in some studies as the most effective compared with ibuprofen or paracetamol [71]. Ketorolac is a non steroidal anti-inflammatory drug (NSAIDs) that interferes with prostaglandins by blocking cyclo-oxygenase. Ketorolac is effective for 45 minutes when administered intravenously, and has a 6-hour half-life. Administering this drug at the beginning of surgery, instead of at the end, improves its effectiveness because strabismus surgery duration is short. One disadvantage with this drug is a higher risk of bleeding because it produces less platelet aggregation, which is a common side effect with NSAIDs. Topical analgesia using drops with NSAIDs has proven effective in some studies [72], but not in others [73, 74].

Some possible reactions produced by NSAIDs are: angioedema, rhinitis, and exacerbation of asthma or bronchospasm [75-79]. So this should be considered in asthmatic patients because a proportion of them (20%) are sensitive to aspirin and other NSAIDs [80, 81]. These reactions have been observed in ophthalmologist procedures and after administering NSAIDs such as ibuprofen, diclofenac and ketorolac [82]. Hence they are not highly recommended in strabismus surgery.

PREVENTING AND TREATING POSTOPERATIVE NAUSEA AND VOMITING

Although anesthesiologists are aware of this complication in postoperative strabismus surgery, its incidence is still too high.

In the last few decades, different guides have attempted to standardize its management in the clinical practice, but no clear algorithm has been found.

PONV incidence in childhood lies between 33.2% and 82%, and its incidence is double in adults [83-87]. This high incidence explains antiemetic prophylaxis instead of treatment [84, 88, 89].

Although there are many causes of PONV, surgery type has a strong influence [22]. Strabismus surgery and ear-nose-throat, such as adenoidectomy or tonsillectomy, are associated with a PONV incidence of between 54-82%, and with a post-prophylaxis incidence of 33-36% [21, 83]. PONV in strabismus surgery is due to EOM traction producing the oculoemetic reflex [90]. Joo et al. demonstrated that there was no relation between the number of muscles operated in strabismus surgery and PONV [91].

PONV can result in a range of complications, including wound dehiscence, dehydration, electrolyte imbalance, subconjunctival bleeding, delayed patient discharge, likely readmission, or even pulmonary aspiration [69, 92].

Anesthesiologists can reduce the risk of PONV with different therapeutic managements [88]: 1) avoiding volatile anesthetics and preferably using total intravenous anesthesia (TIVA) with propofol; 2) preferably using regional anesthesia or combined with general anesthesia to use postoperative opioids less; 3) multimodal therapy for postoperative pain to use postoperative opioids less; 4) avoiding nitrous oxide; 5) suitable hydration; 6) avoiding neostigmine.

The use of NSAIDs in multimodal analgesia is controversial because of the higher risk of bleeding during surgery, although some studies have proved that the incidence of bleeding after its use is no higher, as well as a lower PONV incidence [93].

Regarding hydration, several studies have demonstrated that high doses of intravenous liquids (30 ml/kg/h) for strabismus surgery have been associated with a lower emesis incidence than standard therapy (10 ml/kg/h), and with a lower PONV incidence, from 54% to 22% [21, 83].

Other factors that have been demonstrated to lower PONV incidence are gastric emptying under general anesthesia and prolonged postoperative fasting [94-96].

Different drugs can reduce PONV, such as droperidol, 5-HT₃ antagonists (ondansetron), dimenhydrinate, dexamethasone and metoclopramide [20, 97]:

- 1) Droperidol: is a butyrophenone that produces the central antagonism of the receptors of dopamine in the chemoreceptor trigger zone. Because of side effects, like prolonged sedation, extrapyramidal side effects, agitation, anxiety and prolonged QT, this drug has been recommended as a rescue therapy if PONV is only refractory [98]. QT prolongation is a contradiction for its use.
- 2) 5-HT₃ antagonists: are first-line drugs recommended for PONV. Ondansetron is one of the most frequently used and most effective, and is a serotonin central antagonist of the 5-HT₃ receptor [89, 99, 100, 101]. Its use is associated with minimal side effects, absence of sedation and extrapyramidal effects. This drug could have a dose-dependent effect, and is able to lower PONV incidence, even with low doses at 0.1–0.15 mg/kg iv [102].

The main concern lies in the possibility of triggering cardiac dysrhythmias by QT prolongation. However, some studies have proven QT prolongation as being insignificant when using therapeutic doses of this drug [103].

A drop in PONV incidence up to 50% has been observed after using a 5-HT₃ antagonist [101]. Other studies have indicated a minor PONV incidence when

tropisetron is combined with dexamethasone (PONV of 24.4%), compared to tropisetron alone (PONV of 53%) [104]. A clear advantage has been also observed with ramosetron (PONV of 8.3%) over ondansetron (PONV of 21.3%) [105]. Even in strabismus surgery, PONV with ramosetron was 9% [91, 106].

- 3) Dimenhydrinate: is an antihistamine drug with an antiemetic effect. It is a cheap drug with good antiemetic effectiveness [107]. It may have a similar effect to 5-HT₃ receptor antagonists, dexamethasone and droperidol. However, this drug could produce greater sedation and require better observation during the postoperative period. In fact its duration and dose-response have not yet been studied [108].
- 4) Dexamethasone: is a glucocorticoid used for PONV. No consensus about a dose-response relationship has been reached from published studies. Some studies have shown no difference with the various doses used (0.0625, 0.125, 0.25, 0.5 or 1 mg/kg until a maximum dose of 24 mg) [109, 110]. Instead other studies have found a reduced PONV dose-response and have favored higher dexamethasone doses of up to 0.5mg/kg [111]. Hence nowadays more randomized dose-control trials are necessary to recommend suitable doses of this drug in such cases [112]. The remarkable side effects of this drug are tumor lysis syndrome, a serious complication with low dexamethasone doses, which produce hyperkalemia, hyperuricemia, hypocalcemia and hyperphosphatemia, which could result in kidney failure, cardiac arrhythmias, seizures, and even death [113]. Toxic effects have also been observed in children with hematologic cancer who received dexamethasone [114, 115]. This drug also causes a higher blood glucose concentration [116].
- 5) Metoclopramide: is a benzamide that acts as a central peripheral dopaminergic antagonist to increase the lower esophageal sphincter tone and to enhance gastric motility. The side effects of metoclopramide include sedation and extrapyramidal effects.

Available studies that analyze the effectiveness of metoclopramide compared to other drugs are limited, so we must be careful with their results. It has been demonstrated to be an effective drug, and one with no dose dependency. Ondansetron has been shown in some studies to be more effective than metoclopramide at doses of 0.5 mg/kg [117]. So metoclopramide should not be used routinely as a prophylactic drug. The risk factors for PONV are: previous PONV or a family history of PONV, duration of anesthesia (> 30 minutes), age (≥ 3 years), underlying diseases (e.g., general sickness), female sex, no smoking, use of volatile anesthetic, use of opioids during the perioperative and postoperative periods, and kind of surgery (strabismus surgery, orchiopexy and tonsilloadenoidectomy) [118, 119].

Several factors can increase PONV incidence in strabismus surgery: visual disturbances, anesthetic technique and oculocardiac reflex. Oculocardiac reflex is a central reflex due to ocular muscle manipulation, which has been described by Van den Berg et al. [69].

Risk factors should be treated to lower PONV incidence and to make a good pharmacological prophylaxis with antiemetics, by maintaining it for the first 24 h in strabismus surgery [91]. Doses and administration times are important, as is performing a good combination of different kinds of drugs to optimize the effect.

ABSTRACT

Low grade gliomas (LGGs) are infiltrative primary brain tumors with a typical slow evolution. LGGs occur in young and otherwise healthy patients, which poses a great challenge for the neurosurgeon in maximizing resection while preserving neurological functions, namely increasing time to progression and overall survival while preserving patient's quality of life. Brain mapping, intra-operative advanced cortical and subcortical mapping for motor, language and higher order functions as well as mapping stimulation protocols currently in use in the Department of Neurosurgery - Neuro-oncology, King's College Hospital are presented. Future challenges in brain mapping are also discussed in light of the current knowledge on the actual distant propagation of direct electrical stimulation as a methodology to study the brain connectome organization.

Keywords: low grade gliomas, brain mapping, neuromonitoring, white matter, connectome

INTRODUCTION

Intra-operative mapping for resection of infiltrating low grade gliomas (LGGs) located in eloquent regions of the brain such as motor, language and higher order functions is nowadays considered mandatory in order to achieve maximal tumor resection, while preserving neurological functions (Figure 1) and consequently improving quality of life to those patients [1].

Figure 1. MRI T2-weighted (left image) and T1-weighted (right image) showing a typical low grade glioma of the left opercular region with involvement of both motor and language cortical and subcortical structures.

Cortical and subcortical brain mapping requires an *a priori* knowledge of the cortical and subcortical anatomy, namely the white matter tracts, which integrity is required to preserve the functions. Correct stimulation parameters and a detailed preoperative strategy are mandatory in viewing of maximizing the tumor resection [2, 3, 4].

Hence, we discuss in this chapter the value of LGGs' extent of resection, and how to acquire the complex three-dimensional white matter fibers anatomical knowledge necessary to adequately perform mapping throughout the surgical resection. We provide an historical perspective of the brain mapping techniques and we analyze the anesthetic and neurophysiological protocol for brain cortical and subcortical mapping of motor, language and higher order functions that we currently use in our Department of Neurosurgery – Neuro-oncology, King's College Hospital. We also briefly discuss the cortico-cortical evoked potentials as a future tool for online *in vivo* mapping of the brain connectome.

LOW GRADE GLIOMAS: VALUE OF EXTENT OF RESECTION

Infiltrating LGGs are slow growing brain tumors which affect young and middle aged adults. They present with seizures and only rarely they manifest with neurological deficits, regardless the fact that LGGs grow continuously. The linear diameter growth rate of the

lesion is on average 4mm/year [5, 6]. When volumetric analysis is performed, the linear volumetric growth is 0,187 cm³/month [7]. LGGs inevitably transform to higher grades malignancy which is associated with high rates of morbidity and mortality [8].

The surgical and oncological strategy and timing of treatment of LGGs has been controversial. A cohort study population-based compared the survival outcomes in two Norwegian regions where different surgical approaches were applied. It has demonstrated a remarked advantage in favor to early surgical resection compared to watchful waiting strategy [9]. In fact, the median survival in the watchful waiting strategy cohort was 5.8 years compared to 14.4 years in the cohort of patients where early resection was advocated. In those watchful waiting strategy, the survival rate was of 60% for biopsy patients, while for those receiving early surgery was of 74%. Moreover, the effect of early resection is sustained after adjustment for molecular markers according to the new WHO classification of low grade tumors. Those data favor an early LGGs resection strategy in order to achieve a higher survival outcome.

Not only early resection of LGGs seems to play a crucial role in patients' outcome but also the extent of resection. The malignant transformation rate of LGGs ranges from 4 to 29 months, being 45% within 5 years from the diagnosis. Smith et al. demonstrated that individuals with at least 90% extent of resection have an extended time progression free survival and a 5-year survival rate of 97%, compared with patients with less than 90% extent of resection which showed a 5-year survival rate of only 76% [1] (Figure 2).

Figure 2. Early postoperative MRI within 24 h from the surgery showing complete resection of a right supplementary motor area low grade glioma. Intraoperative cortical mapping of hand and forearm (top left image). Intraoperative subcortical mapping of the corticospinal tract and in particular of the tibialis anterior muscle during tumor resection (right top image).

In light of the abovementioned data, low grade gliomas pose a unique challenge: maximizing extent of resection while preserving neurological functions. In order to achieve the oncological benefits from maximizing extent of resection, accurate intraoperative mapping should be performed either in anaesthetized or awake patients according to the structures involved by the tumor as well as patient's wishes taking to account job, hobbies and cultural background.

WHITE MATTER FIBER DISSECTION AS A PROPEDEUTIC TRAINING TO LGGS SURGERY

The white matter of the brain consists of myelinated bundles of nerve fibers, known as fascicles or tracts (Figure 3). These fibers form a complex three-dimensional architecture within the hemispheres. *Brain mapping of the different brain compartments and subcortical structures cannot be performed without an in-depth understanding of the white matter fiber system.*

To ensure consistency and reliability of brain mapping to effectively guide the surgical resection, direct electrical stimulation (DES) cannot be applied without a strong *a priori* hypotheses and a detailed knowledge of how white matter fiber systems and networks are organized. Precise neuroanatomical hypotheses are then confirmed with DES [10].

The white matter fiber dissection technique performed according to Joseph Klingler allows the surgeon to build the anatomical mental imagery to be coupled with current state of the art knowledge about networks sub serving different brain functions as motor and language. Mastering this dissection technique is mandatory in order to tailor surgical strategy to each patient according to tumor relationships with white matter tracts as well as vascular and subarachnoid spaces' anatomy [11].

Figure 3. White matter fiber dissection technique as per Joseph Klingler's methodology. This technique unveils the complex three-dimensional architecture of the white matter fiber system of the brain, which is propaedeutic to intraoperative brain cortical and subcortical mapping. 1: arcuate fasciculus, 2: inferior fronto-occipital fasciculus, 3: claustrum, 4: external capsule.

HISTORICAL PERSPECTIVES OF BRAIN MAPPING TECHNIQUES

Brain mapping using Direct Electrical Stimulation (DES) of the neural structures finds his pioneers in Fritsch and Hitzig in 1870. They stimulated the motor cortex of dogs and were able to elicit movements. In 1874, Ferrier characterized the brain's motor centers in macaque, and later on in 1901 Sherrington and Grunbaum replicated the same experiment in great apes. In 1917 Leyton and Sherrington noticed that different motor area representations such as fingers, forearm and arm overlap within the precentral gyrus.

Krause and Cushing in 1909 were the first group to perform DES in the human brain eliciting motor responses, and a decade later, in 1919, Vogt and Vogt tried to link brain functions to the anatomy using DES. Later, in 1937 Penfield and Boldrey described a simplified representation of the somatotopy of the body on the cortical surface, calling it "Homunculus." In 1957, Purpura et al. attempted to use DES to study the contribution of dendritic potentials in the modulation of the electrical activity output at the brain surface [10]. In 1960s the use of electrical microstimulation (EMS) refined the methodology for studying the brain in animal models, however, it is not currently used in humans.

DES is nowadays performed to guide the surgeon in cortical and subcortical mapping of eloquent functional areas including motor, sensory and language throughout the LGGs resection (Figure 4).

Figure 4. Direct cortical stimulation (DES) mapping with a bipolar probe for cortical and subcortical language mapping. Patient is awake performing specific language tasks. DES of language areas causes a transient perturbation of the network. The black line indicates the tumor boundaries defined using intraoperative ultrasound. The number 7 on the cortical surface represents a cortical site which when stimulated caused transient nomimum dysphasia.

THE USE OF INTRAOPERATIVE NEUROMONITORING AND NEUROLOGICAL OUTCOME IMPROVEMENT

Seven retrospective studies, class III evidence, have demonstrated the impact of intraoperative neurophysiological monitoring in order to achieve improved neurologic

outcome for language [12-18] and motor functions [16, 17, 18] in LGGs resection. In 2003, Duffau et al. investigated cortical and subcortical language and motor mapping in 103 resections of LGGs, in which 94% of the cases resulted in favorable functional results [17]. 3 years later, a follow up study by the same group reported no permanent deficits in patients that received insular LGGs surgery with motor and/or language mapping. Yordanova et al. reported a surgical approach using DES mapping to extend the resection beyond the MRI boundaries of the tumor. This led to supra-total resections of 15 out of 17 cases, which improved progression free survival (PFS) rate compared to a control group of patients undergoing total resections of LGGs [14]. Even though functional mapping seems to favor neurological outcomes, patients with tumors in eloquent areas identified through DES mapping exhibited decreased overall survival in comparison with tumors in non-eloquent locations, due to the limitations dictated by highly functional structures as for example the corticospinal tract or the arcuate fasciculus [12] (Figure 2). Sarubbo et al. reported no permanent deficits in their patients and a 78% of volumetric resection achieved and Karnofsky Performance Status improved in 8 out of 12 patients [13].

Benedictis et al. reported 9 cases in which patients underwent a second awake craniotomy demonstrating that the extent of resection could be improved in all 9 cases. This result suggests that a process of plasticity may take place [15].

A study of motor mapping in LGGs identified subcortical tracts in 89% of 26 LGGs. In the 11% where corticospinal tracts could not be identified the gross total resection (GTR) rate improved from 44 to 67% [16]. The identification of subcortical tracts was directly correlated with higher probability of immediate postoperative deficits, which however usually resolved within 1 month [16] (Figure 5).

Figure 5. Direct cortical stimulation for motor and language mapping. A strip electrode of 4-contact channels is placed over the precentral gyrus for continuous monitoring of MEPs throughout tumor resection as an adjunct electrophysiological tool to ensure safety.

ANAESTHESIA DURING BRAIN MAPPING IN ASLEEP AND AWAKE PATIENTS

While brain mapping of primary motor functions and corticospinal tract can be performed with the patient anaesthetized, higher order functions as language require the patient to be awake and collaborative with the surgeon while resection of the tumor is carried out.

Awake craniotomy can be undertaken awake from the beginning to the end or with the asleep-awake-asleep or the asleep-awake-awake protocols. The setup of the anaesthesia is similar in all three protocols, with placement of two venous cannulas, an arterial cannula and a urinary catheter.

In awake only craniotomy, sedatives are often used to relieve the boredom for the patient and to enable them to tolerate staying still for prolonged periods. The drugs to maintain this state must not interfere with the conscious state below minimal sedation. Dexmedetomidine is an ideal anaesthetic, as it is short acting and titratable. Other drugs such as propofol and remifentanyl can be used but they are more depressant on the respiratory system. Longer acting drugs such as midazolam need to be used with care as they are less titratable. No sedation at all can be given but all patients will need adequate local anaesthetic to tolerate pins and craniotomy while awake.

Delivering adequate oxygen without interfering with the patient's ability to communicate needs to be considered. Oxygen masks muffle the voice and nasal speculums can irritate, both have limitations on the maximal delivery of oxygen concentrations. Thrive/optiflow is a well tolerated delivery system of humidified high oxygen concentration via the nasal route. The disadvantage is that currently there is not a simple way to monitor the end tidal carbon dioxide and respiratory parameters.

In the asleep-awake-asleep/awake technique, the advantage is that pinning and bone flap removal can be done easily and quickly under general anaesthesia, waking the patient only when the tumor resection is performed. Placing a laryngeal mask airway (LMA) instead of an endotracheal tube is an ideal airway technique if the patient is suitable (i.e., not too obese). This allows smooth emergence while in pins with the open skull and avoids the need for muscle relaxation and reversal. Optiflow or other oxygenation devices need to be placed from the outset to ensure they are sitting correctly after removal of the airway. As with awake craniotomy, dexmedetomidine is ideal as it preserves respiratory function and is easily titratable. As before, the drugs propofol and remifentanyl are used for both the GA and sedation. The use of depth of anaesthesia monitoring allows anaesthetics to be titrated to effect to allow quick intraoperative wake up. During the awake phase anaesthetics can be stopped completely or titrated to effect to maintain patients comfort.

After removal of the tumor, a joint decision between the surgeon, anaesthetist and patient takes place as to whether the patient remains awake/sedated or returns to GA for closure of the craniotomy. An LMA is needed in this situation due to the position and open cranium.

As with any awake case, signage on the operating doors and minimal movement of staff around the theatre help to keep an atmosphere of calm. Keeping the patient warm is important and temperature should be monitored to prevent hyperthermia.

Careful patient selection and preoperative education is vital to the success of awake craniotomy. Close cooperation between surgeon, anaesthetist, neurophysiologist and speech and language therapist is vital to maintain safety and smooth running of the surgery.

METHODOLOGY FOR FUNCTIONAL MAPPING

Neurophysiological monitoring and mapping in brain tumor surgery involves simultaneous acquisition of continuous electroencephalography (EEG), electrocorticography (ECoG), multichannel recording of free-running electromyographic activity (EMG), motor-evoked potentials (MEPs), and somatosensory evoked potentials (SSEPs). It can be done either under general anaesthesia or awake state. We preferentially perform awake craniotomies only when language mapping and higher order functions mapping are required, which include asleep-awake-asleep anaesthesia protocol.

In asleep-awake-asleep protocol, cortical motor mapping is first performed with the patient asleep which produces more reliable results. In fact, the voluntary movements of the patient make the interpretation of the MEPs responses more challenging. Moreover, the conscious sedation used in awake patients have antiepileptic properties that affect the interpretation of the stimulation. Following cortical motor mapping, cortical and subcortical language mapping is performed with the patient awake as well as motor subcortical mapping.

Given the epileptogenic effect of direct electrical cortical stimulation, ice-cold saline is used in case of stimulation-triggered after-discharges, aborting triggered epileptiform or epileptic activity.

SSEPS AND PHASE-REVERSAL

SSEPs are obtained by stimulation of peripheral nerves, the most commonly used being the median nerve at the wrist and posterior tibial nerve at the ankle (Figure 6). For stimulation of the peripheral nerves we use subdermal needles (Friend Hip Medical, 13 mm length) and a constant current stimulator (ISIS Neurostimulator, InomedGmbH) integrated into a ISIS Xpress System (Figure 7). The electrical stimulus delivered is a positive pulse form of 0.2-0.5 msec width, delivered at a frequency of 3.1 or 3.7 Hz, averaged at least 20-200 stimulation trials. Current intensity is increased until thumb muscle twitches are observed.

Mean EP traces are obtained by averaging electrophysiological signals time-locked to the DES. Evoked potentials (EP) are recorded by subdermal corkscrew needles (Friend Hip Medical, 0.6 mm diameter) positioned in the postcentral parietal regions (C3', C4', Cz', Fz), according with the 10-20 International Electrode System. Electrodes may need to be repositioned to other locations due to bone flap. SSEPs in brain procedures are useful for detecting vascular injury during tumor resection.

The functional mapping protocol starts with the accurate identification of the central sulcus by SSEPs phase reversal technique. This technique is performed by stimulation of the median nerve or ulnar nerve (in case of arterial line), and recording through a strip electrode of 4-6 contacts (Dixi medical, France). The contacts are placed over the exposed cortex (or epidurally) at the level of the hand area on the convexity, in a perpendicular position. For more median exposure towards the inter hemispheric fissure, posterior tibial nerve stimulation can be used.

Figure 6. SSEP responses at baseline and closing. Left windows – Left and right median nerve responses (N20 waveforms). Right windows – Left and right posterior tibial nerve responses (P40 waveforms). Green traces: baseline responses.

EP responses are recorded using a monopolar derivation with the reference electrode, subdermal corkscrew needle, placed on the contralateral mastoid. Reversal in polarity of the scalp-recorded median or tibial thalamocortical SSEPs is observed at about 19 msec after the stimulation of the contralateral nerves (Figure 7).

Figure 7. Median nerve SSEP phase reversal technique using 4-contact (1,2,3,4) strip electrode and referential recording (Fz), with reference electrode on the contralateral mastoid. Phase reversal is observed between contact 2 and 3. The electronegative potentials seen at contact 1 and 2 represents the N19/22 thalamocortical potential obtained in the postcentral somatosensory cortex. Scalp SSEPs responses displayed on the top (N20 waveform) helps to distinguish somatosensory responses from motor responses. Right image: ISIS Xpress System, Inomed GmbH.

CORTICAL AND SUBCORTICAL MOTOR MAPPING

Following identification of the central sulcus via the phase-reversal technique, DES is applied to the primary motor cortex using a monopolar probe or bipolar probe. We preferentially use the monopolar probe (Inomed, Inomed GmbH) as this provides a homogeneous radiant spreading electric field, which increase the probability of stimulating

nervous tissue at more distant sites and, therefore, provides higher sensitivity [19]. Moreover, it seems to be less epileptogenic (Figure 8).

Anodal train-of-five stimulation is used at 1 Hz frequency, with 0.5 msec pulse width, and 2 msec duration, using a constant current stimulator (ISIS Xpress System, Inomed GmbH) [20]. The primary motor cortex is first identified at the motor threshold defined at the lowest intensity allowing MEPs recorded in the contralateral hemibody muscles. This is followed by a higher stimulation, normally in our department we use 10 mA, for identification of supplementary motor regions. Lastly, higher-stimulus intensity is applied to the surroundings of the regions to be resected for safer “entry zone.”

Figure 8. Monopolar probe is used for DES of the primary motor cortex. Number 1 showing a positive response from flexor carpi ulnaris muscle of the hand. Tumor can be appreciated behind the Vein of Troland running in the central sulcus in this particular case.

MEP responses time-locked to the DES of the motor areas are recorded using subdermal needle electrodes (Friend Hip Medical, 13 mm or 17 mm length) inserted in face, upper and lower limbs muscle groups of the contralateral hemibody, connected to a multichannel EMG recording (Figure 10). For facial muscles we use orbicularis oculi, orbicularis oris, tongue and masseter. For upper limb we use deltoid, biceps, brachioradialis, flexor carpi ulnaris, dorsal interosseous, thenar and hypothenar. For the lower limb we include quadriceps, anterior tibialis, gastrocnemius and abductor hallucis. Moreover, free-run EMG of voluntary motor activity is run using the same muscle groups.

Subcortical mapping of the corticospinal tract can be achieved using the train-of-five technique and cathodal stimulation (Figure 9). We normally set a current intensity of 10 mA and, after a motor response is detected, a stepwise resection towards the corticospinal tract is achieved decreasing the current up to the limit of 5 mA. For a quicker detection, we increase the frequency of stimulation to 2 Hz.

Figure 9. Cortical and subcortical mapping of the hand and foot over the precentral gyrus while the patient performs awake finger-tapping test for fine motor movements intraoperative assessment.

Throughout tumor resection, MEPs are run repeatedly to continuously assess the functional integrity of the motor pathways. MEPs are obtained using a strip electrode (4-6 electrodes) placed over the precentral cortex and using the train-of-five technique (Figure 10). Each contact is tested with a vertex reference.

Figure 10. MEP responses obtained from stimulation of the primary motor cortex through a strip electrode (4- contacts). MEPs were recorded continuously throughout procedure. Motor responses were recorded from flexor carpi ulnaris (FCU), abductor pollicis brevis (APB) and first distal interosseous (FDI) muscles. Scale: 70 msec, 300 μ V/DIV.

CORTICAL AND SUBCORTICAL LANGUAGE MAPPING

DES applied to the cortical and subcortical structures essential for speech functions is able to inhibit part of the network during few seconds.

For speech mapping we perform the Penfield stimulation technique using a bipolar probe (2 mm diameter ball tips, spaced 5 mm apart, InomedGmbH) (Figure 4). Biphasic square wave pulses of 1 msec duration are applied at a frequency of 50 Hz (Europe) for 5-8 sec using a constant current stimulator (ISIS Neurostimulator, Inomed GmbH). The threshold of current is set at the minimal current to evoke language errors without triggering after discharges in the electrocorticography (ECoG), in an incremental fashion of 2 mA. If the ventral premotor cortex can be exposed, the threshold is defined during a counting task. DES is applied during a comprehensive language testing such as verbal fluency, repetition, visual object naming, sentence comprehension, and word generation.

To distinguish motor arrest, speech arrest, and anomia, free-run EMG recordings are accomplished alongside with DES. Subdermal needles (Friend Hip Medical, 13 mm length) are placed on the *orbicularis oris* muscle and *masseter*.

EEG AND ECoG

EEG and ECoG are used complementary to monitor depth of anaesthesia, and spontaneous or triggered after discharges minimizing the risk of stimulation-triggered seizures (Figure 5). EEG is recorded by subdermal corkscrew needles positioned in the postcentral parietal regions, used simultaneously for SSEP, recordings of each hemisphere referred to a midfrontal electrode for referential derivation. For the ECoG recording, a subdural strip electrode (Dixi medical, France) is placed over the exposed cortex (Figure 5). ECoG is also helpful for ruling out non-convulsive but focal seizures throughout resection. EEG and ECoG recordings are filtered (bandpass 0.5 – 100 Hz) running at sensitivity of 30 mm/sec (Figure 11).

EMG modality parallel with EEG and ECoG also allows for early detection of the spreading of muscle activation over a limb as a sign of seizures.

Figure 11. ECoG recorded during speech mapping. Left window – Baseline ECoG. Right window – electric seizure induced during speech mapping using 7 mA current intensity. The channels are numbered 1 through 5, with the top being channel 1. Reference electrode on the contralateral mastoid. The recording settings for the ECoG are: Low-frequency filter 0.5 Hz, high-frequency filter 100 Hz, and sensitivity 1 mV/Div.

HIGHER ORDER COGNITIVE FUNCTIONS: INTRAOPERATIVE MAPPING

Patients receiving awake surgery with language intraoperative mapping still experience post surgical neurocognitive deficits when a more accurate neuropsychological assessment is performed [21, 22]. Therefore, there is a need for mapping higher order functions intraoperatively, specifically in the context of performing a supra total resection, in order to be able to accurately balance the extent of resection against quality of life preservation.

Specific tests should be tailored to each individual patient, for example according to the characteristics of his/her job, due to the constraints given by the intraoperative fatigue and consequently the limitation of the tests that can be performed. For example, mapping calculation (multiplication and subtraction) has been used as an intraoperative test for a school teacher with a lesion involving the left parietal lobe, in order to preserve her from developing dyscalculia [23].

Dissociation between language tested by picture naming and nonverbal comprehension tested by a semantic task of association has been demonstrated. Specifically, for surgery involving the dominant posterior temporo-visual areas naming test might be of importance [24].

Moreover, it has been shown that executive functions are often impaired after brain surgery [21, 22] affecting cognitive domains as decision making, and planning of complex strategy. Therefore, several intraoperative tests have been proposed to task recent memory - by performing stimulation during storage, encoding or retrieval in lesions within the temporoparietal and frontal sites-; to task attention -testing ocular saccades in patients with lesions involving the frontal eye fields eliciting stimulation or suppression of ocular deviation-; to task visuo-verbal congruent and incongruent judgment in lesions of the prefrontal cortex.

Non ultimately maintenance of visuospatial attention by eliciting transient partial neglect intraoperatively is paramount in all cognitive domains in order to receive the correct stimuli to be processed from the environment. In this context a fronto-parietal network with a line bisection task and reaching test could be mapped intraoperatively in the non-dominant hemisphere (Figure 12).

Figure 12. Intraoperative Bisection line test while patient awake used to map the non dominant Fronto-parietal networks.

CORTICO-CORTICAL AND AXONO-CORTICAL EVOKED POTENTIALS

In 1935 Foerster and Altenburger were the first to use electrocorticography (ECoG) to record electrophysiological responses to DES in various parts of the brain distant from the motor areas [10]. However how the stimulus induced by electrical stimulation is propagated still remains unknown. Recording evoked potentials generated by DES far away from where the stimulus is applied represents a way to have an in-depth view on stimulus propagation (Figure 13). In particular, DES can be used to probe the spatio-temporal connectivity and the dynamics of short and long range networks in vivo and in real time. This approach requires the combination of electrophysiological recordings -EEG or ECoG- with the stimulation technique (Figures 5, 13).

Figure 13. Combination of DES and intraoperative Stealth guided EEG recording is used to probe the spatio-temporal connectivity and the dynamics of short and long range networks in real time during brain surgery.

Matsumoto et al. [25] observed that low-frequency cortical application of DES (1Hz, constant current and alternating rectangular wave pulses lasting 0.3 ms) induces cortico-cortical evoked potentials (CCEPs) around 10-50 ms after stimulation.

The evoked potentials were observed in contiguous cortical areas whose centers were up to 3 cm apart linked by subcortical pathways. Single pulse DESs were delivered to certain functional areas of the cortex and CCEPs were measured by averaging the ECoG signal recorded at other sites.

Keller et al. [26] found that non contiguous and distant brain cortical areas even 5 cm apart exhibited strong evoked potentials (lasting from 10 to 30 ms) with low frequency DES. More interestingly Keller et al. demonstrated that low frequency fluctuations in BOLD signal in functional resting state MRI are representative of the brain's functional architecture when correlated with CCEP findings. As a consequence, low frequency DES can propagate in long

range networks with functional relevance through subcortical pathways and not only grey matter.

In our experience we were able to elicit also axono-cortical evoked potentials (ACEPs) when stimulating at the subcortical level -the arcuate fasciculus- while recording from the ventral premotor cortex (Figure 5). This means that probably the electrical stimulus, applied with DES at a subcortical level while distal cortical recording is achieved, can propagate through discrete subcortical pathways.

While CCEPs and ACEPs recording in neuro-oncology is still at an early stage, however they represent in our perspective a valuable tool to study the human connectivity *in vivo* and eventually guide low grade glioma resection also based on the dynamics of the whole network.

FUNCTIONAL PLASTICITY OF ADULT CORTEX: A STRATEGY TOWARDS EXTENDING LGG RESECTION?

Plasticity is an inherent feature of the human brain. Defined as the ability to change in response to experience, brain plasticity allows for the development and maintenance of nervous system function [27]. In particular, involvement of brain plasticity in clinical recovery from ischemic stroke [28] and infiltrative brain tumors has been clearly described [29]. However, those findings are derived from non-invasive studies conducted with functional MRI (fMRI), positron emission tomography (PET) and transcranial magnetic stimulation (TMS).

DES of brain cortex and subcortical structures during low grade glioma surgeries in patients receiving two or more brain mapping surgeries can be used as a direct tool to examine functional reorganization.

A longitudinal study comparing cortical brain mapping in two different surgeries in the same patient showed that nearly 40% of patients demonstrated a rearrangement of their functional maps between initial and repeated surgeries [30]. More interestingly patients who showed loss of function at one or more stimulation sites still exhibited intact or stable motor and speech function at the time of repeat surgery.

Tumor volumes at time of the initial surgery were significantly smaller in patients who exhibited functional reorganization (34.1 ± 23 cm³ in those with reorganization vs 69.9 ± 32.2 cm³ in those who did not, $p=0.02$) [30], possibly meaning that brain plasticity reserve decreases when tumors reach a critical volume. As a consequence, early surgery for low grades might be warranted in order to use at best the inherent plastic potentials of the brain cortex for functional recovery. However, mechanisms of functional rearrangement still need to be understood [31].

Advances in non-invasive methods as fMRI, TMS and Magnetoencephalography as well as in CCEPs invasive recordings could perhaps lead to careful observation of functional reorganization, with the aim to perform a more aggressive resection once functional circuits have been redistributed in areas not necessarily infiltrated by the lesion.

A STEP BACK: IS THERE A BIOPHYSICAL RATIONALE FOR DES?

While Electrical Microstimulation (EMS) is applied to animal fundamental neuroscience experiments, DES is performed on humans in the operating theatre. It is sometimes wrongly assumed that EMS and DES induce similar effects and findings in animal models are wrongly translated into humans.

At the current state of the art there is no solid biophysical rationale for setting the stimulation parameters in EMS and DES, probably due to historical, methodological and technical constraints. EMS and DES techniques are applied differently to the nervous tissue and use very different parameters. Moreover, even though DES is used effectively in tumors resection, the underlying electrophysiological effects needs to be yet defined.

The gap between empirical intraoperative DES and EMS in a laboratory setting offers an invaluable opportunity to gain insights on how DES perturbs a large functional network with physiological and behavioral relevance [10]. In particular, the study of CCEPs and ACEPs and the propagation of the stimulus along the white matter pathways will probably offer an invaluable tool for an in-depth understanding on the relationships between DES and neural networks.

CONCLUSION

At the state of the art intraoperative neuromonitoring coupled with direct cortical and subcortical stimulation for brain mapping of motor, language and higher order functions represents the gold standard to achieve maximal resection of low grade gliomas while preserving neurological functions, hence patient's quality of life.

In depth knowledge of the neuroanatomy of white matter fibers, by means of white matter fiber dissection technique, as well as of principles and interpretation of intraoperative neuromonitoring and brain mapping protocols is mandatory in order to correctly and effectively perform intraoperative mapping.

An *a priori* hypothesis of the functional networks possibly involved by the tumour is *conditio sine qua non* for the neurosurgeon to operate on intrinsic low grade brain tumors.

Stimulus spreading of DES is still matter of debate. Research on CCEPs and ACEPs could represent a valuable tool to unveil widespread and bilateral networks on line and in vivo, namely the dynamics of brain connectivity.

BIOGRAPHICAL SKETCH

Christian Brogna, MD, PhD

Affiliation:

Department of Neurosurgery - Neuro-oncology - King's College Hospital
Department of Basic and Clinical Neuroscience
Maurice Wohl Clinical Neuroscience Institute
King's College London Institute of Psychiatry, Psychology & Neuroscience

Education:

Dr. Christian Brogna completed his neurosurgical training in 2009 at “La Sapienza” University of Rome, Italy. He studied Neuroanatomy under the mentorship of Prof. Guilherme Ribas in Sao Paulo, Brasil. He did a fellowship in awake surgery and brain mapping with Prof. Hugue Duffau, CHU de Montpellier, France. He trained with Prof. Ugur Ture, Istanbul, in advanced Microneurosurgical Techniques in Brain Tumour Surgery. Mr. Christian Brogna earned his PhD in Neuroscience in 2013.

Business Address:

125 Coldharbour Lane
London SE5 9NU
United Kingdom
christian.1.brogna@kcl.ac.uk

Research and Professional Experience:

Dr. Christian Brogna is an expert in complex brain and spinal cord tumour surgery. In particular he operates on brain tumours located in highly eloquent areas of the brain, for example those areas involved in motor and language functions in order to preserve patient's quality of life. He conducts research in advanced techniques in brain and spinal cord mapping for safe tumour resection.

Professional Appointments:

Dr. Christian Brogna currently operates on Brain and Spinal Cord Tumours in the Department of Neurosurgery, King's College Hospital. Dr Christian Brogna has an academic appointment with King's College London University and is responsible for translational neurosurgical research in neuro-oncology.

Publications from the Last 3 Years:

Chapter 444

THE EFFECTS OF LIPOIC ACID ON WOUND HEALING IN A UTERINE INJURY RAT MODEL: CLINICAL PERSPECTIVES IN OBSTETRIC SURGERY

Asli Goker* and Naci Kemal Kuscü

Department of Obstetrics and Gynecology, Manisa Celal Bayar University,
Manisa, Turkey

ABSTRACT

Healing of the uterus after an obstetric or gynaecologic intervention is of great importance to maintain further pregnancies. Wound healing of the uterine tissue has not been widely studied but is gaining more importance with increasing caesarean rates in modern times.

Alpha lipoic acid, an anti-inflammatory and antioxidant compound has been studied in many fields of treatment. Wound healing is shown to be enhanced by alpha lipoic acid. A study on the effect of alpha lipoic acid on wound healing in a rat model and a general overlook about the compound has been reported.

Keywords: uterine injury, alpha lipoic acid, wound healing

INTRODUCTION

The uterus is a unique female genital organ which serves for fertility. Trauma to the uterus may cause infertility, miscarriage or uterine rupture in a pregnancy.

The most frequent causes of uterine damage are caesarean section (CS), myomectomy and curettage. Uterine wound healing is of vital importance because dehiscence of uterine scars or rupture during a subsequent pregnancy or parturition may be life threatening for mother and/or baby.

* Corresponding Author's Email: asligoker@gmail.com.

Uterine wound healing has not been widely studied and there are not well designed and convincing articles about the subject. Little is known on the mechanisms and factors influencing adequate tissue regeneration.

Various molecules which may have positive impact on uterine wound healing have been studied: a promising compound is Alpha Lipoic Acid (ALA) and the first experimental study on its effect on a full thickness injury in a rat model will be discussed later.

INTERVENTIONS TO THE UTERUS

Uterine fibroids are the most common benign tumours of women after the third decade with a prevalence rate of 20–50%, based on post-mortem studies (Laughlin, Schroeder, and Baird 2010, Novak, Novak, and Woodruff 1979). In modern times women tend to postpone their pregnancies after reaching a certain career status and thus their childbearing years coincide with the time of high fibroid incidence (Schmidt et al., 2012).

Approximately 5-10% of the infertile patients have fibroids (Benecke et al., 2005) and some of them undergo myomectomy either by laparoscopy, laparotomy or robotic surgery.

The major concern about myomectomy is the risk of uterine rupture in a subsequent pregnancy, and this risk is not related to the mode of surgery. A history of myomectomy leads to prefer CS in pregnant women especially if more than 50% of the myometrium has been exposed during the surgery (Roopnarinesingh, Suratsingh, and Roopnarinesingh 1985). Uterine rupture may cause the displacement of the foetus into the abdominal cavity leading to perinatal demise and maternal haemorrhage causing blood transfusions, hysterectomy or even maternal death.

The precise risk of uterine rupture in a pregnancy following myomectomy remains unknown but is reported as high as the risk in a patient with previous CS. The risk increases when it is an intramural fibroid (Brady, Stanic, and Styer 2013).

The risk of uterine rupture during trial of labour after myomectomy is reported as 0.47% - 0.8% mainly occurring before 36 weeks of gestation (Gambacorti-Passerini et al., 2016, Kim et al., 2016). However, it is indicated by the World Fibroid Registry that most uterine ruptures after myomectomy are not reported especially if no complication occurred (Kim et al., 2016). Most reported cases do not include silent ruptures (Kim et al., 2016). There are cases of spontaneous uterine rupture, at 20 weeks of gestation with a myomectomy-pregnancy interval of 6 years (Pakniat, Soofizadeh, and Khezri 2016).

An increase in hospitalization due to fibroids is estimated to increase 23% by year 2050 (Wechter et al., 2011). Open, laparoscopic or hysteroscopic myomectomies are recommended even in asymptomatic infertile women if the cavity is distorted (American Society for Reproductive Medicine 2017). Since physicians will continue to perform myomectomies, the risk of uterine rupture in future pregnancies will remain as a major and a life-threatening problem.

Another uterine intervention is CS and it is among the most common surgical operations worldwide. Even though it is life-saving in most cases, maternal complications may arise and future pregnancies may be affected.

There is no supporting evidence that CS has maternal and/or perinatal benefits and the World Health Organization (WHO) is trying to maintain a certain rate of CS procedures.

Though CS is of great benefit in many conditions, it is still debatable to perform in uncomplicated deliveries due to increase in maternal complications in subsequent pregnancies and financial costs. The WHO statement on CS concludes that caesarean sections are saving maternal and infant lives, at population level they should be performed only when required for medically indicated reasons.

Rates exceeding 10% are not associated with reductions in maternal and newborn mortality rates, therefore more research is needed to understand the health effects of CS on immediate and future outcomes (World Health Organization 2017). Despite this statement, caesarean section rates range from 3% in Western Africa to 42.9% in Southern America and almost 20% of women worldwide give birth by CS (Betran et al., 2016). The most frequent indications for elective CS are fear of vaginal birth and physicians' fear of facing a litigation (Habiba et al., 2006).

Elective repeat CSs are associated with increased risk of uterine rupture, placental invasion anomalies and placenta previa (Barger et al., 2012). Vaginal birth after caesarean (VBAC) was considered as a good alternative method to decrease repeat CSs, however VBAC rates dropped since mid 1990's due to health care providers' choice (Tsai and Wu 2017). The American College of Obstetrics and Gynaecology (ACOG) has recently released Practice Bulletin 184 and reported that women can avoid major abdominal surgery and have lower rates of haemorrhage, thromboembolism and infection with a successful VBAC.

The risk of hysterectomy, bowel-bladder injury, abnormal placentation and infection may decrease with VBAC in women who are planning future pregnancies. The final statement of ACOG is "Most women with one previous caesarean delivery with a low-transverse incision are candidates for and should be counselled about and offered trial of labour after caesarean" (Committee on Practice Bulletins-Obstetrics 2017) and therefore the rate of uterine rupture or dehiscence which contribute to maternal and neonatal morbidity or mortality may decrease.

Since physicians will continue to perform myomectomy and CS, the significance of good wound healing is of great importance to achieve a durable incision site. Wound healing is a process involving complex interactions of mediators. Following tissue injury, keratinocytes migrate to the injury site and then granulation formation by fibroblasts and endothelial cells and neovascularization occur. Blood vessels are repaired, restored and regenerated (Fosen and Thom 2014).

The classic steps of wound healing comprise inflammation, proliferation and remodelling. In mammals, reactions to trauma is repair and regeneration with numerous molecules participating in the process (Tonnesen, Feng, and Clark 2000).

The female reproductive tract is constantly exposed to tissue injury. Menstruation and parturition are physiological injuries whereas gynaecologic or obstetric procedures such as curettage, myomectomy, hysteroscopic resection and CS are widely applied and traumatic interventions. Initiation of endometriosis is another example of inflammatory response and healing of menstrual wounds (Leyendecker, Wildt, and Mall 2009). Similarly, fibroids are found to represent keloids in abnormal healing and disordered collagen fibril organization (Leppert et al., 2004). Therefore, understanding the mechanism of the endometrial, myometrial and serosal regeneration of the uterus is of great importance.

WOUND HEALING

Skin lesions are widely studied to understand the mechanism of wound healing but so far there is little information on uterine pathways. Even though most wounds heal with scar formation, this is usually not the case in endometrial repair, like the absence of granulation formation or blood clots (Salamonsen 2003).

The healing of foetuses is without scar formation, however in anti-inflammatory deficient foetuses, wounds heal with scarring. This indicates a role for inflammation in the scar formation (Liechty et al., 2000).

The major molecules participating in wound healing are growth factors, cytokines, extracellular matrix molecules and matrix degrading enzymes (Salamonsen 2003). Endometrial repair includes stromal mitoses, re-epithelization, vascular repair, proteolytic enzymes, growth factors, endothelin, inflammatory cells and chemokines.

An important modulator related to angiogenesis is vascular endothelial growth factor (VEGF) which is found to be expressed during post-menstrual repair (Graubert et al., 2001). A study investigating uterine injury in humans' reports that healing may result by myometrial hyperplasia, elastosis or myofiber disarray (Roeder, Cramer, and Leppert 2012). What is known regarding the underlying mechanisms of healing in female genital tract is that inflammation and angiogenesis are key points in uterine wound healing. Despite this, further studies are necessary to better investigate this complex process.

ALPHA LIPOIC ACID

Alpha lipoic acid (ALA) is an organosulfur compound derived from octanoic acid and its R-enantiomeric form is synthesized endogenously. Plants, animals and human tissues rich in mitochondria synthesize ALA and it is present in reduced, oxidized and disulfuric forms (Biewenga, Haenen, and Bast 1997).

Under physiological conditions, ALA is amphipathic which allows it to pass the blood-brain barrier and show its effects both in an aqueous and lipid environment (Wada, Shintani, and Ohlrogge 1997). This versatility clearly has advantages on other hydrophilic or hydrophobic antioxidants. The antioxidant property of ALA has shown to enhance vascular functions in diabetic skin lesions and diabetic kidneys (Lateef et al., 2005, Micili, Ergur, et al., 2013).

Numerous trials and experiments are carried out about the possible therapeutic fields of ALA such as cancer (Yang et al., 2017, Nur, Naziroglu, and Deveci 2017, Alpay et al. 2016), polycystic ovary syndrome (Genazzani et al., 2017), diabetes (Jurisic-Erzen et al., 2017), tissue regeneration (Mazroa et al., 2015, Ekinci et al., 2014, Aydin et al., 2014, Chen et al., 2012) and protection from ischemia/reperfusion damage (Lv et al., 2017, Ambrosi et al., 2016). Most studies have found positive impact on molecular and tissue levels.

Clinical use of ALA seems to be promising in many clinical conditions which involve inflammation, oxidation and tissue damage in their pathophysiology. Experimental and clinical trials have shown that ALA decreases growth factor receptor bound protein-2 in lung cancer cells, increases apoptosis and ROS production by activating TRPV-1 in breast cancer, decreases insulin, glucose and HOMA index levels in polycystic ovary syndrome, increases

TGF-beta in femoral fracture model, controls inflammatory reaction, enhances elastic fiber synthesis and improves angiogenesis in mesh application (Yang et al., 2017, Nur, Naziroglu, and Deveci 2017, Genazzani et al. 2017, Mazroa et al., 2015, Aydin et al., 2014).

After oral intake, ALA is quickly and nearly completely absorbed, however due to hepatic first-pass effect its bioavailability is limited (Locher, Busker, and Borbe 1995). Recent experiments investigated the vaginal administration of ALA to verify its distribution in uterine and cervical tissues after vaginal application of ALA to rats. Samples of the endometrium, myometrium and perimetrium have shown that normal histomorphological structure had been maintained and the stroma was consistent with the oestrus cycle of the rats. This indicates that ALA reaches uterine tissues when applied vaginally and does not impair the histomorphologic structure. Immunohistochemical studies of the endometrium have shown staining of simple columnar epithelium, endometrial glands and stroma with anti-ALA antibody, showing us that vaginal route for ALA is effective in reaching target tissues of uterus (Micili et al. 2018).

The safety of ALA in animals and humans have been shown by numerous other studies (Rahimifard et al., 2015, Cremer et al., 2006, Parente et al., 2017).

The most important function of ALA is its antioxidant effect by scavenging oxidants, regenerating endogenous antioxidants, chelating transition metals and repairing oxidative damage (Monastra et al., 2016). Besides anti-inflammatory and immunomodulatory effects, ALA has been shown to have angiogenetic stimulating features (Paradells et al., 2015).

FULL THICKNESS INJURY IN A RAT MODEL

The VEGF family is specific to endothelial cells and takes part in cell proliferation, migration and differentiation (Neufeld et al., 1999). In addition, VEGF plays an important role in angiogenesis during the granulation process of wound healing (Nissen et al., 1998). Considering that VEGF plays an important role in angiogenesis and ALA is a potential anti-inflammatory and antioxidant compound it has been used in an experimental model.

In a study, Cilaker et al., produced a full thickness injury in the uterus, mimicking CS or myomectomy with the endometrium disposed (Micili, Goker, et al., 2013). Alpha lipoic acid was used to determine its effects on the healing process due to its numerous features.

The authors studied VEGF and smooth muscle actin (SMA), a marker for fibrogenesis and myofibroblast generation. The alpha form of SMA is present in fibroblasts and myoepithelial properties which are active in wound healing by contracting the edges of the injury site (Cherng, Young, and Ma 2008).

Besides angiogenetic induction in tissues, VEGF is essential for re-epithelization of the endometrium, and has been used in tissue engineering and wound healing (Ferrara and Kerbel 2005, Ferrara 2004, Fan et al., 2008). Lin et al., showed that, after injection of collagen into a scarred rat uterus, VEGF promoted remodelling of the scarred uterus including, the regeneration of endometrium, muscular cells and vascularization and improved pregnancy outcomes (Lin et al., 2012).

The experimental study by Cilaker et al was carried out on Wistar albino rats which were randomly assigned to five study groups. Group 1: control group, group 2: uterine scar group 15 days, group 3: uterine scar + ALA treatment 15 days, group 4: uterine scar group 30 days,

group 5: uterine scar + ALA treatment 30 days. The experiment was done on day of diestrus phase. Full thickness injury was modified from Lin et al.'s model (LIN). After full-thickness injury was created on the uterine horns of the rats.

Alpha Lipoic acid treatment was administered as fresh solutions by oral gavage. According to study groups 15 or 30 days later relaparotomy was performed to retrieve uterine horns for histological examination and immunohistochemistry.

The thickness of the regenerative uterine wall in Control group uterus ($687.5 \pm 85.7 \mu\text{m}$) was higher than all other groups ($p < 0.001$). The uterine wall thickness was significantly higher in the US15d+ALA ($483.4 \pm 45.7 \mu\text{m}$) and US30d + ALA ($619.1 \pm 61.4 \mu\text{m}$) groups when compared to the US15d ($248.3 \pm 56.8 \mu\text{m}$) and US30d groups ($503.9 \pm 56.5 \mu\text{m}$), respectively ($p < 0.001$). No significant difference was observed between US15d + ALA and US30d groups ($p = 0.571$).

The percentage of α -SMA positive area in US15d + ALA (20.3 ± 1.54) and US30d + ALA (28.1 ± 2.98) groups was significantly higher than US15d (15.2 ± 3.20) and US30d groups (21.07 ± 1.59) ($p < 0.001$, $p < 0.001$).

The percentage of VEGF positive area in US15d + ALA (23.3 ± 2.92) group was significantly higher than US15d group (16.0 ± 1.95) ($p < 0.001$) and US30d + ALA (25.8 ± 2.59) group was significantly higher than US30d group (21.3 ± 1.94) ($p < 0.001$).

Groups treated with ALA had a comparable uterine wall thickness with control which was a similar result to Li et al.'s bFGF treatment group.

A significant increase in α -SMA expression both by immunohistochemical and biochemical methods lead us to conclude that ALA has an enhancing effect on smooth muscle cell regeneration. An increase in the expression of tissue α -SMA refers to an increase in myofibroblast activity, thus ALA may have a triggering effect on fibrogenesis during wound healing.

A study by Buhimschi et al., demonstrated regenerative ability as histological, mitotic and functional differences in mice strains with different healing capacities (Buhimschi et al., 2010). They showed that, the site of uterine scar was active and underwent significant remodelling transformation even at 15 days post caesarean delivery which was equivalent to 7.5 months in humans. The risk of uterine rupture from the incision site due to dehiscence is highest in the postoperative first 2 years in humans (Stamilio et al., 2007).

The study by Cilaker et al., evaluated the effect of ALA at day 15 and 30 after uterine full thickness injury and have seen a significant healing in the group treated with ALA for 15 days. These results propose a possible positive effect of ALA on uterine wound healing and point out a probable clinical use of this molecule to accelerate tissue regeneration after surgery.

CONCLUSION

Many studies showed the positive effect of ALA on wound healing. Supplementation with oral ALA has been shown to down-regulate chronic inflammatory state by changing the protease/anti-protease levels, to decrease the matrix metalloproteinase 9 expression and to increase levels of PDGF-BB contributing to the treatment of dermal wound repair (Alleva et al., 2008).

Treatment with ALA has been shown beneficial for fracture healing in an animal model (Aydin et al., 2014).

The study by Cilaker et al opens a new scenario for ALA clinical use in gynaecology and obstetrics representing the first experimental example on the use of oral ALA for uterine injury healing.

Further experimental and clinical studies on this field of application are warranted to further investigate the efficacy of ALA and the development of new ALA-based drugs and/or medical devices may represent an opportunity for clinicians and patients.

Chapter 445

SEX DIFFERENCES IN TERMS OF EATING BEHAVIORS, BIOLOGICAL AND PSYCHOLOGICAL FEATURES: A REVIEW IN THE BARIATRIC SURGERY POPULATION

Braga, Portugal

ABSTRACT

Bariatric surgery has showed to be a successful weight loss treatment, which has been mainly performed on women. Sex entails differences on biological, behavioral and psychological features along with social-cultural factors that might be important in predicting outcomes after surgery, as well as on the (re)emergence of eating-related problems and psychopathology in the post-operative time. However, research addressing sex differences after bariatric surgery is scarce. The aim of this chapter is to summarize the existing literature on sex differences in obesity and bariatric surgery population.

Men and women are biologically different in terms of body fat distribution and gonadal hormones. For example, male patients have higher body mass index and higher probability of developing medical complications following gastric bypass surgery in all weight ranges, whereas in women obesity-related risk factors, for instance pregnancy or menopause, may play a role in the physiological and behavioral consequences of appetite and weight regulation. These differences lead to diverse behaviors and attitudes towards food.

Regarding eating behavior, although eating disorders, such as bulimia and anorexia nervosa, have been reported in men, they are usually more prevalent in women.. However, women tend to report higher levels of loss of control over eating, while men tend to report more overeating without loss of control. Women also tend to report more

* Corresponding Author's Email: econceicao@psi.uminho.pt.

compensatory behavior such as vomiting or dieting. Likewise women tend to engage more often than man in body checking behaviors.

In the psychological perspective, women are more likely to acknowledge a history of depression, social anxiety, psychological and psychiatric treatment. Furthermore women have more negative thoughts about themselves, and their weight has a greater influence on body image and self-esteem. Similarly, men and women differ on motivations for undergoing bariatric surgery.

Considering all of these aspects, clinical practice and follow-up evaluation should be sex adjusted, and sex should be investigated as a predictor of adjustment to treatment, quality of live and psychological distress after surgery. Understanding such differences and their impact would allow the development of tailored assessment and interventions pre- and post-surgery.

Keywords: bariatric surgery, sex differences, eating behaviors

1. INTRODUCTION

Obesity, classified when Body Mass Index (BMI) is equal or above 30 (Libeton, Dixon, Laurie, & O'Brien, 2004; Moyer, 2012) is currently reaching epidemic proportions in developed and developing countries. While the prevalence of individuals with excessive weight (BMI 25-29.9kg/m²) has been kept stable, the percentage of individuals with obesity (BMI $\geq$ 30kg/m²) and extreme obesity (BMI $\geq$ 40kg/m²) have greatly increased over the past years (Mitchell & de Zwaan, 2005). The problem of overweight and obesity is not limited to adults, and is also a concern among children and adolescents. Obesity is considered the most common nutritional issue worldwide and the most significant contributor for mortality rates surpassing malnutrition and infection diseases (Lau et al., 2007). The causes of obesity are both complex and multifactorial, with genetic, social and environmental factors playing a role. In recent decades, sedentary lifestyles and overeating have exceeded the physical work and the regular physical activity benefits for weight control, resulting in a rapid increase of obesity prevalence seen in the last twenty years. These factors allow to conclude that this increment was motivated mainly by social and environmental causes, and not so much by genetic factors (Lau et al., 2007).

The problem of obesity goes far beyond the aesthetic and body image issue as people with excessive weight or obesity present increased risk for developing a great variety of health conditions, such as hypertension, type 2 diabetes, dyslipidemia, kidney stone, coronary heart disease, stroke, osteoarthritis and some types of cancer (Moyer, 2012). The increasing number of patients needing effective treatments for obesity results in a great demand for health services, and in larger health expenses of these patients. Despite the associated mortality risks and medical morbidity, obesity is also associated with heavy psychosocial consequences such as low self-esteem and self-worth, negative emotions, anxiety, insecurity, negative self-belief, powerlessness and apathy, depression and stress (Hemmingsson, 2014).

Pharmacological treatment, physical activity, diet and behavioral interventions are some of the available treatments (Tsai & Wadden, 2005), but changing and maintaining a healthy lifestyle is still the key for long-term treatment of obesity. However, both the patient and the professionals responsible for treatment face several barriers for long-term maintenance of treatment outcomes (Lau et al., 2007). Such barriers include time constraints, medical

comorbidities (mental health, sleep, pain, cardiovascular, respiratory or digestive disease and endocrine disorders), socioeconomic status, medication, alcohol and substance abuse, and the acceptance of obesity as a chronic disease (Mauro, Taylor, Wharton, & Sharma, 2008). Fortunately, these barriers include aspects that can be modified in order to facilitate adherence to treatments. Thus, identifying and addressing such aspects is crucial for patients to make the lifestyle changes required and adhere to therapy.

When concerning patients with severe obesity ($\text{BMI} \geq 40$) or with BMI over 35 kg/m^2 with two medical conditions associated (such as hypertension or diabetes), bariatric surgery is considered the most effective treatment (Mitchell & de Zwaan, 2005; Niego, Kofman, Weiss, & Geliebter, 2007). Nevertheless, this surgical procedure requires harsh changes in the patient's nutritional pattern and lifestyle. In fact, some authors consider that patients who do not engage in the necessary changes, should be considered not suitable for this treatment (Kushner & Roth, 2003). Furthermore, high surgical risk status, advanced age, endocrine disorders, other comorbidities not treated, as well as addictive behaviors, are some of the contraindications for bariatric surgery (Mitchell & de Zwaan, 2005). Currently, there are a variety of surgical procedures available, which are in constant evolution, influenced by literature results, and medical team of each site (Angrisani et al., 2015). Such techniques differ in terms of their restrictive or malabsorptive nature.

Studies suggest that, for the majority of patients, bariatric surgery has significant effects on long-term weight loss and is associated with a reduction in overall mortality (Sjöström et al., 2004). This surgical treatment results in significant weight reduction, and is consequently accompanied by significant improvements in several comorbid conditions associated with obesity, including diabetes, hypertension, dyslipidemia, vascular disease and sleep apnea (Chang et al., 2014). Additionally, each type of surgery can be performed using minimally invasive techniques such as laparoscopic surgery, or as an open surgery. Procedures performed laparoscopically are less invasive, decreasing the time spent in hospital as well as the recovery time for patients (Colquitt, Pickett, Loveman, & Frampton, 2014).

Adjustable Gastric Banding (AGB) is considered a purely restrictive procedure and involves the placing of an adjustable plastic and silicone ring around the proximal opening of the stomach, immediately below the gastroesophageal junction, creating an approximate 20 ml upper gastric pouch. This restrictive surgery is the least invasive for obesity treatment. However, success rates are lower than 50% and failure rates reach 40% at 7 years after treatment. Therefore, a rising number of authors consider that AGB should not be the procedure of choice for treating patients with excessive obesity (Papamargaritis, Pournaras, & Le Roux, 2010).

In turn, in Sleeve Gastrectomy (SG), a restrictive procedure as well, the stomach is transected vertically creating a gastric tube and leaving a 150-200ml pouch. The remaining stomach is excised (Papamargaritis et al., 2010). This procedure leads to weight loss by restraining food ingestion, presenting lower risks when compared to other procedures which implicate the implantation of medical devices and malabsorptive procedures (Braghetto et al., 2007). The percent excessive weight loss for SG varies from 33% to 90% and appears to be sustained up to 3 years. The expected mortality rate is 0-3.3%, and major complications are thought to range from 0% to 29% (average 12.1%) (Shi, Karmali, Sharma, & Birch, 2010).

In Roux-en-Y Gastric Bypass (RYGB) the stomach is divided into the upper stomach pouch, which is 15-30 mL in volume, and the lower stomach pouch, gastric remnant. The stomach pouch is then anastomosed to a distal part of the intestine, eliminating absorption of

food in the proximal intestine (Papamargaritis et al., 2010). This procedure consists in the combination of restrictive and malabsorption techniques, in which patients lose about 60% to 80% of their excessive weight in the first year of treatment. In about 80% of the patients the long-term stabilization of weight occurs by the time when 50% to 60% of weight loss has occurred (Mitchell & de Zwaan, 2005).

In 2013, the surgical procedures made more frequently worldwide were RYGB, 45%, followed by SG, 37% and AGB, 10%. No other surgical procedure exceeded 2.5%. Additionally, the literature mentions that in 2013, 95,7% of bariatric surgeries were preformed laparoscopically, allowing shorter staying at the hospital and less complications when compared to the open approach technique (Angrisani et al., 2015).

Despite the success of this surgical treatment in inducing weight loss and weight loss maintenance in the long-term, the variability of weight outcomes is still of concern (Mitchell & de Zwaan, 2005), and research has sought to investigate the factors associated with poorer results.

Accumulating evidence suggests that sex might be an important factor in understanding the effectiveness of bariatric surgery, and that there are different predictors of success for men and women. Focusing on the importance of sex differences would lead to health and economic improvements of treatments and other support mechanisms for these patients (Lovejoy & Sainsbury, 2008).

In this context, the distinction between the terms “sex” and “gender” should be taken into consideration. The term “sex” refers to differences between men and women that result from the chromosomal complement, the sexual organs and the effects of hormones; the term “gender” refers to an individual’s identity, cultural and behavioral expectations, associated with being a man or a woman (Lovejoy & Sainsbury, 2008).

In the United States, the overall age-adjusted prevalence of obesity has been considered to be higher in women (40.4%) than in men (35.0%) in the recent years of 2013-2014 (Flegal, Kruszon-Moran, Carroll, Fryar, & Ogden, 2016). There seems to be a sex-specific variation regarding obesity prevalence, as for men obesity prevalence varies according to smoking status, with lower prevalence among men who are current smokers than in men who never smoke; for women, education level such as holding a college degree, has been significantly related to a lower risk of obesity (Flegal et al., 2016).

Globally, 85% of the bariatric procedures are performed in women (Buchwald, Estok, Fahrbach, Banel, & Sledge, 2007). Yet, the majority of studies present significant improvements in weight loss for both men and women, showing evidence that bariatric surgery should be encouraged for eligible men. Although, male sex has traditionally been acknowledged as a significant independent risk factor for the development of cardiovascular diseases (and other comorbid diseases), these conditions can be improved after surgery highlighting that men with severe obesity can potentially benefit from bariatric surgery even more than women (Kennedy-Dalby, Adam, Ammori, & Syed, 2014).

The aim of this paper is to summarize the main findings, possible explanations and gaps in the existing literature on differences between men and women in the bariatric surgery population. This chapter is divided into three main sections: (1) differences in biological factors - this section focuses on variances in physiological aspects, weight loss, the effectiveness of treatment in the resolution of comorbidities and complications after surgery, life expectancy and mortality rates; (2) differences on behavioral aspects in terms of eating behavior, eating disorders and problematic eating behaviors; and (3) comparison of

psychological aspects such as depressive and anxiety symptoms, body image dissatisfaction, childhood sexual abuse, motivation for surgery and health help-seeking behavior.

2. BIOLOGICAL FACTORS

2.1. Weight Loss

Weight loss is predicted by different factors and sex is not an exception, particularly because there are distinct variables that have an impact on long-term weight loss (Bekheit et al., 2014).

Clear evidence shows that a higher pre-surgical BMI predicts an increased weight loss (Andersen, Aadland, Nilsen, & Våge, 2014). Male patients with morbid obesity undergoing weight loss treatment tend to lose significantly higher amounts of body weight than women, corresponding also to a higher fraction of their initial body weight (Sartorio, Maffiuletti, Agosti, & Lafortuna, 2005). Men with obesity undergoing weight loss treatment have a higher aerobic capacity which could explain the increased weight loss. Also it is important to note that weight loss in men with morbid obesity consists of a similar amount of reduction in fat mass and fat-free mass, whereas women lose fat mass almost entirely, and fat-free mass appears to be maintained (Sartorio et al., 2005).

Empirical research shows that two years after bariatric surgery men have a higher mean percentage of excessive BMI loss (76.7% to 78.9%), while women lose between 74.8% and 78.8% kg/m² (Perrone et al., 2016).

In the study of Andersen and colleagues (2014) with patients who underwent SG, different predictors of weight loss at 2 years were found for both sexes. Older men without diabetes showed lower percentage of excess BMI loss, whereas for women lower BMI loss was mainly predicted by unemployment and anxiety and/or depression. Additionally, Perrone and colleagues (2016) showed empirical evidence that SG is more effective in male than in female patients in terms of the percent excess BMI loss after 24, 36 and 60 months since surgery.

However, there is evidence that highlights the absence of significant differences between men and women in the mean percentage of excess BMI loss after RYGB (Bekheit et al., 2014; Perrone et al., 2016), and also 24 months after SG (65.8% kg/m² in men vs 72.9% kg/m² in women; Kennedy-Dalby et al., 2014). Although Tymitz, Kerlakian, Engel and Bollmer (2007) found no significant differences between men and women in their BMI after RYGB, male patients continued to weigh more and lost more pounds than females at 6 and 12 months post operation.

Physiological and behavioral differences (such as body composition, physical activity and others sex-specific characteristics described elsewhere in this chapter) between men and women could explain such differences in weight outcomes after bariatric surgery (Perrone et al., 2016).

2.2. Effectiveness of the Treatment on Comorbidities and Surgery Complications

Diseases such as diabetes mellitus type II, hypertension, cardiovascular disease and sleep apnea syndrome are all associated with obesity (Tymitz et al., 2007), and these are also the most common comorbid conditions presented by bariatric surgery patients. Significant differences in preoperative comorbidities and complications rates are observed between male and female patients (Stroh et al., 2012). Men tend to have increased preoperative incidence of these conditions when compared to women (Livingston et al., 2002; Stroh et al., 2013).

Male sex and weight status are considered to be significant preoperative risk factors for the development of severe life-threatening complications following RYGB. For example, the risk of severe life-threatening adverse outcomes increases from 7% in a male patient with 200-lb, up to 13% for a 600-lb male patient, while for a 200-lb female patient the risk rises from 4% to 7.5% when compared to a 600-lb women (Livingston et al., 2002).

Concerning sex differences in perioperative variables, no significant differences have been found on length of hospital stay, intensive care unit stay, overall leaks or other medical conditions such as bowel obstruction, gastrointestinal bleed, wound infection, pulmonary failure, deep vein thrombosis or pulmonary embolism (Tymitz et al., 2007). Although men have a significantly longer anesthesia time, operative time and length during RYGB (Tymitz et al., 2007), for SG no differences on mean operating time are observed between the two sexes (Stroh et al., 2012). Regarding AGB, no sex-specific aspect regarding perioperative complications rates were found (Stroh et al., 2013).

When measuring improvements in comorbidities after SG and RYGB, studies showed great reductions but similar outcomes for both sexes (Kennedy-Dalby et al., 2014; Perrone et al., 2016). However, despite similar improvements in both sexes, remission rates of hypertension after AGB seem to be higher for female patients. Additionally to achieve similar remission rates of comorbidities (e.g., hypertension and diabetes), men have to significantly lose more weight and need longer continuous treatments during the post-operative period (Livingston et al., 2002) compared to female patients (Stroh et al., 2013). In fact, because of the low postoperative remission rates of these comorbidities in men Stroh and colleagues (2013) suggested that AGB may not be a good option for men with a BMI above 45 kg/m², hypertension and/or sleep apnea, and/or diabetes.

Regarding postoperative complications of bariatric surgery, the literature suggests that male sex has a higher probability of developing life-threatening complications following RYGB surgery in all weight ranges (Livingston, Huerta, Arthur, Lee, & Shields, 2002). According to Stroh and colleagues (2012), female sex has a protective effect against complications, while men have significantly higher overall complication and mortality rates because of their higher BMI and higher incidence of comorbidities.

2.3. Life Expectancy and Mortality Rates

Life expectancy is markedly shortened by obesity, particularly among young adults. Being overweight rises the risk of mortality from 6 to 12 times (Fontaine, Redden, Wang, Westfall, & Allison, 2003).

Marked sex and race differences were observed in the estimation of years of life lost (YLL). The YLL index is defined as the difference between the number of years an individual would be expected to live if not obese, and the number of years expected to live if with obesity. White men aged 20 years with BMI greater than 45 are estimated to have 13 YLL compared to white men in the same age with BMI of 24. White women aged 20 to 30 years and BMI over 45 are expected to have 8 YLL due to obesity. Further findings with black population suggest that overweight and obesity may not decrease life expectancy until a BMI of approximately 32-33 for men and 37-38 for women. For example, black men aged 20 years with BMI over than 45 are expected to have 20 YLL, while black women in the same conditions have 5 YLL (Fontaine et al., 2003). Either way, regardless of race, women have less YLL due to obesity when compared to men. However among white men, the number of YLL was generally constant across ages, compared to white women where a higher variance is observed (Fontaine et al., 2003).

Regarding mortality rates after bariatric surgery, studies present a marked decreased over the years, owing to the surgeon experience and to the annually increased performance of these procedures (Buchwald et al., 2007). The risk of early death after surgery is further associated with advanced age, lower number of bariatric procedures performed by the surgeon, and male sex (Flum et al., 2005).

Mortality rates are significantly higher for men than women within the first weeks of surgery (4.74% vs 0.13%, respectively) (Buchwald et al., 2007), at 30 days (3.7% vs 1.5%, respectively), 90 days (4.8% vs 2.1%, respectively) and 1 year (7.5% vs 3.7%, respectively) after surgery (Flum et al., 2005). Male sex has been associated with higher mortality rates either after laparoscopic or open procedures (Tymitz et al., 2007). Additionally, male patients undergoing RYGB have a 3-fold higher risk of mortality than women. Although there is little research on the factors underlying these differences, differences in body composition and diminished physiologic tolerance to stress in men have been suggested (Livignston et al., 2002). Curiously, higher incidences of comorbidities in male sex was not associated with higher perioperative morbidity and mortality rates (Tymitz et al., 2007).

2.4. Physiological Differences

Sex differences in obesity can be explained in part by differences in body fat distribution, composition, and chromosomal factors and gonadal hormones which influence appetite. However behavioral and socio-cultural aspects may also play a role (Lovejoy & Sainsbury, 2008).

It is widely accepted that biological factors determine that men tend to be taller, larger, heavier and also to present a greater BMI (Grilo, Masheb, Brody, Burke-Martindale, & Rothschild, 2005; Livingston et al., 2002; Stroh et al., 2013). Both before and after bariatric surgery, men's BMI remains significantly higher than women's (Mahony, 2008; Stroh et al., 2012). Women tend to be shorter, weigh less, and have less fat-free mass and more fat mass than men (Lovejoy & Sainsbury, 2008). Notwithstanding, BMI has been considered an inaccurate estimate of body composition (Lovejoy & Sainsbury, 2008), and the use of other methods that reflect body fat and lean content have been encouraged, especially when comparing men and women whose body composition differs, even at the same absolute weight and height.

Regarding body composition, men and women with obesity differ when gaining weight. Males display concomitant increases in fat-mass and fat free mass, while women present a significant increase in fat-mass with a minimal increase in fat free mass (Lafortuna, Maffiuletti, Agosti & Sartorio, 2005). The literature also points to sex differences in body fat distribution. Men with obesity and postmenopausal women tend to accumulate more abdominal and visceral fat, whereas premenopausal women have greater inferior body gluteo-femoral fat (Després et al., 2008). These differences may be a result of differences in sex hormones between men and women. Estrogen reduces visceral fat in both men and women. Yet, opposite effects of sex hormones on fat distribution in men and women are seen, decreasing visceral fat in men, but increasing in women (Lovejoy & Sainsbury, 2008).

Pregnancy and menopause are specify moments in a women's life with physiological and behavioral consequences on appetite and weight regulation that confer an elevated risk of obesity in women (Lovejoy & Sainsbury, 2008). The prevalence of maternal obesity has increased along with the obesity epidemic worldwide. In the United States, nearly one in two women in childbearing age are overweight or obese. It is observed that non-Hispanic black women at childbearing age are 2.25 times more likely to be overweight or obese when compared to non-Hispanic white women. Some socio-cultural factors may explain the racial and ethnical disparity such as educational attainment, household income, and stability of health insurance coverage (Vahratian, 2009).

Furthermore, the majority of women in developed countries gain more weight than what is recommended during pregnancy. Excess weight gain in pregnancy is of concern in part because it is associated with increased long-term risk of obesity for the mother (Amorim, Rössner, Neovius, Lourenço, & Linné, 2007).

Besides the health impact of maternal overweight and obesity for the women herself, the consequences for the newborn are also of concern. Increased maternal BMI has been associated with increased infant mortality rates, rising from 2.4/1000 among women with normal weight to 5.8/1000 among women with obesity (BMI over 40.0) (Johansson et al., 2014). Also the incidence of type-one diabetes in children with non-diabetic parents can be partly explain by maternal overweight or obesity (Hussen, Persson, & Moradi, 2015). Children of women who exceeded gestational weight gain recommendations are 46% more likely to be overweight or obese at 2-5 years of age. However, if gestational weight gain is below recommendations, especially among normal weight women, there is also an increased risk (23%) of subsequent childhood overweight/obesity (Sridhar et al., 2014).

Men's and women's weight varies and increases gradually during adulthood. Women experience a serious weight increase when pregnant, changing weight trajectory in short-term compared to what would be expected in the absence of pregnancy (Yakusheva, Kapinos, & Weiss, 2017). Obesity in midlife women can be predicted by the failure to lose weight gain 6 months after child-birth and excessive weight gain (Rooney, Schauburger, & Mathiason, 2005). Women who experience weight increases during pregnancy greater than the recommendations tend to retain on average 4.1 kg more in the long-term (up to 15 years) than women with normal weight gain. Women with pre-pregnancy overweight or obesity tend to maintain higher BMI after pregnancy.

Stress seems to be another important factor with relation to obesity and sex differences. Stress has been related to overeating and the development of obesity and abdominal fat accumulation. Sex hormones interact in different ways in response to stress hormones

between pre- and postmenopausal women, however much is still unknown (Lovejoy & Sainsbury, 2008).

Questions related to sex differences in obesity, energy homeostasis and central regulation of appetite have important physiological and clinical relevance for the treatment of these patients (Lovejoy & Sainsbury, 2008). For instances, sex specific physical activity recommendations for weight control could be necessary. Sex-related differences on physical exercise capacity have been observed and related to the marked differences in body composition between men and women. In men with obesity, muscle capacity and strength to perform anaerobic exercise is higher than in women with obesity (Lafortuna et al., 2005). Data available suggest that men and women different in the way physical activity impacts appetite and energy-regulating hormones leading to a different impact on food intake after exercising and different effects on body fat loss for men and women. Women seem to increase food intake in response to the increased energy expenditure after exercising, although no changes in appetite are observed. As a results, the energy deficit from exercising is compensated and hampering weight loss. Men do not seem to increase food intake and seem to experience decrease in appetite, resulting in weight loss because of the energy deficit maintained after exercising. This model partially explains how the practice of physical activity results in different weight trajectories for men and women, and why it is more difficult for women to lose body fat. However, further research is still needed to verify and add evidence to these aspects (Hagobian & Braun, 2010).

3. BEHAVIORAL VARIABLES

After bariatric surgery, the development of eating disorders seems to be a severe postoperative problem (Conceição et al., 2013; Marino et al., 2012). Moreover, in the clinical practice different forms of disordered eating are regularly detected, which do not meet the necessary diagnostic criteria to be considered a full-syndrome psychological disorder, but have a significant impact on daily functioning (Conceição et al., 2014b). Subsyndromal presentations of disordered eating are probably more frequent, but few studies have described and classified them (Marino et al., 2012). However, studies suggest that these maladaptive eating behaviors can reduce or reverse the success of surgery, resulting in difficulties in weight maintenance, medical and psychological morbidity in the long-term (Conceição et al., 2017b; Niego et al., 2007). Thus, further attention should be focused on this area with the aim of systematically investigating the correlates of eating pathology in the bariatric population, and identifying possible risk factors that may compromise the success of these procedures.

3.1. Eating Disorders

The development of bulimia nervosa and anorexia nervosa have been described in women after bariatric surgery. Although no cases were described in men, evidence from the non-bariatric population estimates a lifetime prevalence rate of bulimia nervosa of up to 1.5% and 0.5%, and anorexia nervosa of up to 2.2% and 0.24% in women and men, respectively

(Smink, Van Hoeken, & Hoek, 2012). Considering this literature, health professionals should also consider screening for eating disorders among men undergoing bariatric surgery.

Binge-eating disorder (BED), is the second most common psychiatric diagnosis in bariatric surgery population (Sarwer et al., 2004), and its lifetime prevalence is estimated to be up to 3.6% for women and 2.1% for men (Smink et al., 2012). According to the Diagnostic and Statistical Manual of Mental Disorders (5th ed.; DSM-5; American Psychiatric Association, 2013) BED is defined as binge-eating (BE) - "eating in a discrete period of time (within a 2 hour period), an amount of food that is definitely larger than most people would eat in a similar period of time under similar circumstances... [with] a sense of lack of control over eating during the episode." This loss of control aspects is characterized as "being unable to stop eating or control what or how much was consumed" (Colles, Dixon, & O'Brien, 2008b).

Niego and colleagues (2007) found a high prevalence of BE and BED in patients undergoing weight loss surgery, and suggested that following surgery, maladaptive and psychological distressing eating behaviors continue to be common for many patients. Furthermore, the same authors proposed an association between BE before and after surgery, and indicated that patients sustaining BED or BE after surgery have poorer weight loss outcomes than patients who never had these behaviors or patients who remitted (Niego et al., 2007)..

Given that a higher percentage of patients undergoing bariatric surgery are women (Zizza, Herring, Stevens, & Carey, 2003), research on these eating disorders in men is scarce. However, when assessing the prevalence of eating disorder symptoms in the overweight community, Striegel-Moore and colleagues (2009) found significant sex differences on most behavioral eating disorder symptoms, with more women than men reporting loss of control over eating and more men than women reported overeating. Both sexes presented high levels of inappropriate compensatory behaviors, although with higher frequency for women. There were no sex differences on laxatives and exercise practice behavior (Striegel-Moore et al., 2009).

In turn, when investigating the psychological factors associated with binge eating in men and women, some authors found that depression plays an important role in the maintenance of binge eating symptomatology among both sexes. Women were more depressed than men, felt more negatively about themselves because their weight, and spend more time dieting, while men reported being less disturbed about their weight (Mazzeo, Saunders, & Mitchell, 2006).

Night eating syndrome (NES), recently included in the DSM-5 as an otherwise specified eating disorder, is characterized by conscious episodes of evening or nighttime hyperphagia, manifested by the ingestion of at least 25% of food consumption after the evening meal and/or nocturnal awakening. NES has been associated with emotional distress when reported at least two times per week (5th ed.; DSM-5; American Psychiatric Association, 2013). Studies found that 6 out of 10 subject with NES before surgery may develop this behavior after surgery, and that NES is more prevalent in men than women (Colles, Dixon, & O'Brien, 2008a). Also, the impact of NES in the weight maintenance is still unclear (Conceição et al., 2015), as this area remains understudied.

According to these data, eating disorders and particular BED are serious condition with impact on the bariatric surgery outcomes, and despite the sex differences described, men should also be target population for the screening of these problems.

3.2. Problematic Eating Behaviors

Grazing has received an increased interest among clinicians and researchers for its high occurrence (Conceição et al., 2014a; Conceição et al., 2014b) and association with poor weight loss or weight regain following bariatric surgery.

After surgery, the gastric capacity is reduced and eating large quantities of food, necessary for the diagnosis of BED, is likely impossible. Even though, patients may learn to circumvent these conditions imposed by surgery by eating more frequently, emerging a new behavior labeled grazing- Grazing is characterized by the repetitively eating of modest amounts of food in an unplanned and repetitive manner throughout a period of time (Conceição et al., 2014a). Colles, Dixon and O'Brien (2008a), assessed the nature and development of a variety of eating behaviors before and after surgery, and found that 26.4% of participants before surgery, and 38% of participants at 12 months after surgery reported grazing. In patients undergoing this treatment, grazing appears as a factor strongly associated with poor weight loss and with weight regain. This behavior is relatively frequent among the bariatric population, as well as among nonclinical samples (Conceição et al., 2014a). Nevertheless, when estimating sex differences, similar scores were found for both sexes in the repetitive eating questionnaire [Rep(eat)-Q] designed to assess grazing behavior (Conceição et al., 2017a).

Emotional eating is characterized by eating in response to emotional distress (Fischer et al., 2007; Lindeman & Stark, 2001). This behavior was found preoperatively in both females and males (Hörchner, Tuinebreijer, & Kelder, 2002). This emotional eating pattern is estimated to be present in 38% of bariatric population (Miller-Matero et al., 2014), but there are still mixed findings regarding its association with weight loss after bariatric surgery. Although some authors did not find such association (Fischer et al., 2007), increasing evidence suggests that eating in response to emotional cues has a negative impact in weight loss (Lindeman & Stark, 2001). Despite being more frequent in women, both sexes seem to report this behavior (Gade, Hjelmestaeth, Rosenvinge, & Friborg, 2014), highlighting the need for attention in both men and women.

4. PSYCHOLOGICAL VARIABLES

4.1. Depressive and Anxiety Disorders

Individuals with obesity tend to present higher rates of mood and anxiety disorders in comparison with the community population (Mühlhans, Horbach, & de Zwaan, 2009). In general, female bariatric surgery candidates are more likely to report a history of depression (45.7% for women vs. 17.4% for men), social anxiety (23.2% of women vs. 10.4% of men), as well as a history of psychotherapy (36.5% of women vs. 15.9% of men) (Mahony, 2008).

Depressive disorder is the most common psychopathology diagnosed in bariatric surgery population (Sarwer, et al., 2004), which is associated with unhealthy lifestyle, poor physical activity, lower social interaction and higher caloric intake behavior, resulting in long term weight regain. Depression itself explains about 4% weight loss variance in bariatric patients (Legenbauer, et al., 2009).

Research supports that the presence of preoperative depressive disorder predicts postoperative depressive symptomatology at 24-36 months. However, preoperative depression was not found to be a predictor of short term depression (6-12 months after surgery; de Zwann et al., 2011). Within the first years of surgery substantial improvements are observed, particularly in patients with higher baseline depressive symptomatology who tend to experience larger reductions (de Zwann et al., 2011; Mitchell et al., 2014). However, studies also suggest a gradual increase of such symptoms after 12-36 months of surgery (Mitchell et al., 2014; White et al., 2015).

Reduction in depressive symptoms has been positively related to changes in BMI (Mitchell et al., 2014). Increased levels of postoperative depressive symptoms are associated with poorer weight outcomes 6 to 12 months following surgery, as well as with greater eating disorders symptoms and poor quality of life 24 month after surgery (White et al., 2015).

On the contrary, anxiety seems to have a different course of evolution in bariatric patients when compared to depression. In general, the prevalence of anxiety disorders seems to be maintained following surgery (de Zwaan et al., 2011). The presence of preoperative anxiety tends to predict postoperative anxiety disorders (de Zwaan et al., 2011). Regarding its association with weight loss, preoperative lifetime anxiety was found to be a predictor of poor weight loss after surgery, while postoperative anxiety disorder showed no association with the degree of weight loss at any follow-up time-point (de Zwaan et al., 2011).

Comorbid psychiatric problems can co-occur in bariatric surgery candidates. The presence of baseline, lifetime and current anxiety and depressive disorders have been negatively associated with the degree of weight loss after surgery. Accordingly, patients with anxiety and depressive disorders tend to lose less weight after surgery (de Zwaan et al., 2011). Women with a diagnosis of anxiety and/or depression had a lower percentage of excess of BMI loss than those without these diagnoses, while no such association was observed for men (Andersen et al., 2014).

Empirical evidence suggests that sex and socioeconomic status may be moderators of depressive symptoms in obesity: women with obesity tend to report greater depression levels within high socioeconomic status, but reduced depression among low socioeconomic status women. Such association with socioeconomic level was not observed in men (Faith, Matz, & Jorge, 2002).

4.2. Body Image Dissatisfaction

The perception of men's and women's body image along with emotional factors seems to play a significant role in the development, maintenance and treatment of obesity, as well as in preventive strategies (Lovejoy & Sainsbury, 2008).

Literature relating to body image dissatisfaction among obese and bariatric patients remains mixed (Grilo et al., 2005). Among patients with extreme obesity seeking bariatric surgery, females tend to report significantly higher levels of body image dissatisfaction (Grilo et al., 2005), to diet more, and to be more likely to allow their weight to interfere with how they feel about themselves (Mahony, 2008; Mazzeo et al., 2006).

For both men and women undergoing bariatric surgery, body image dissatisfaction seems to be correlated with greater frequency of binge eating disorder, higher depression levels and low self-esteem. Predictors such as sex, binge eating disorder and self-esteem explain 56% of

body image dissatisfaction variance in men, and 33% in women. Body image dissatisfaction is thought to be under multifactorial influence, highlighting the importance of global adult functioning in understanding body image dissatisfaction as a whole (Grilo et al., 2005).

Patients undergoing bariatric surgery, regardless of sex, tend to improve significantly their perception of body image within the first 6 months, mainly due to major weight loss, positively influencing quality of life (Nickel et al., 2017). Nonetheless, after surgery patients face body deformities and loose skin, which has been associated with overall impairment in sexual functioning, body image and depressive symptomatology, as well as with greater weight regain in women (Ramalho et al., 2015). Undergoing plastic and reconstructive surgery for body contouring is known to improve both quality of life and body image (Song et al., 2006). Women (75%) are the ones who seek such treatments the most and show more interest in body contouring surgeries than men (68%) (Kitzinger et al., 2012). Nonetheless, only 6% of patients after bariatric surgery fully complete this type of surgery (Altieri et al., 2017).

In the matter of body checking and body avoidance in the community sample, significant differences between sexes have been reported, with women being more likely engage in these behaviors. About one in five women check their body size at least “very often,” as for men statistics points that one in ten engaging in the same behaviors (Striegel-Moore et al., 2009).

4.3. Childhood Sexual Abuse

Childhood sexual abused (CSA) victims are more likely to suffer from extreme obesity (Gustafson & Sarwer, 2004), and history of CSA is considered to be a possible threat for successful weight loss after bariatric surgery (Larsen & Geenen, 2005). The majority of victims tend to be female (32% female and 14% male in general population), whereas males tend to suffer more physical abuse than females (Briere & Elliott, 2003).

The relation between weight loss after treatments and CAS is unclear. Sexual abused is considered a psychosocial risk factor for conditions under which obesity may be caused, exacerbated or maintained (Wiederman, Sansone, & Sansone, 1999). Women with obesity and history of CSA tend to lose less weight after a behavioral weight management program, than women without such history (King, Clark, & Pera, 1996). On the other hand, Larsen and Geenen (2005) suggested that CAS did not appear to impact weight outcomes after bariatric surgery in women. With mixed data no clear position has been establish (Livhits et al., 2012).

Contrary to expectations, sexually abuse women with obesity seem to display less weight fluctuations when compared to not abused women with obesity (Wiederman et al., 1999). The ideal-current body weight discrepancy (i.e., body dissatisfaction), seems to be predicted by the interaction between obesity and sexual abuse in women. Women with obesity and history of sexual abuse report relatively less current body dissatisfaction compared to non-sexual abused obese women. Accordingly, Wiederman and colleagues (1999) showed that women with obesity and history of sexual abuse seem comfortable about their weight and appearance, and only a small percentage wanted to look slimmer. The authors justify these apparent discrepancies with the adaptive function of obesity as a defense mechanism to protect themselves from sexual advances, sexual proposals or sexual relationships. Accordingly, women with obesity and history of sexual abuse are less motivated to lose weight, being willing to look less attractive, to avoid physically intimate relationships. Additionally, these

women showed to be psychologically more comfortable at a higher weight, which reduce anxiety-trauma association (Wiederman et al., 1999).

Although women with CAS who are candidates for bariatric surgery seem to experience no increased anxiety compared to non-CAS candidates, the literature suggests that these patients need additional psychological treatment for their mental health (Larsen & Geenen, 2005).

Finally, research has showed that male individuals with eating disorders, such as binge eating disorder who suffered sexual abuse experience greater body dissatisfaction when compared to women in the same conditions (Grilo & Masheb, 2001).

4.4. Motivation for Surgery and Health Help-Seeking Behavior

Health issues dominate the general motivation for seeking surgery. Nonetheless, Libeton and colleagues (2004) found that men and women differ on the reasons for seeking bariatric surgery. Generally, men were more likely than women to be motivated by medical problems, while women seem to indicate aesthetical aspects. The first reason that women indicate for undergoing bariatric surgery is to improve appearance, followed by health concerns, medical condition, physical limitation, embarrassment and physical fitness. Whereas for men, the most important reasons are medical condition and health concerns, followed by physical fitness, physical limitation, and finally embarrassment and appearance (Libeton et al., 2004).

Help-seeking is a complex phenomenon with multiple influencing factors aside from sex, such as age, ethnicity, lifestyle choices, masculine ideology and identity, perceptions shaped by social and cultural factors, and core beliefs (Galdas, Cheater, & Marshall, 2004).

The literature is not consensual regarding the differences between men and women in health help-seeking behaviors in the community population. Many studies report that men underuse health services in comparison with women, others find increased help seeking in men, and one study found no significant difference between sexes. More than just sex, other aspects, such as occupational and socioeconomic status, may play a role (Galdas et al., 2004).

Studies supporting that men tend to underutilize healthcare services, suggest some delay in help seeking when they feel sick and the same is expected for weight loss treatments (Galdas et al., 2004). Possible socio-cultural beliefs are exalted to understand such differences. Although men tend to have higher risk behaviors for obesity, they tend to ignore health symptoms through denial, normalization, under-evaluation. Physical symptoms are the most determining factors for seeking medical help, while emotional symptoms are a minor concern, delaying treatment seeking for depression (Möller-Leimkühler, 2002). Men tend to report higher substance abuse (Alavi, Mehrdad, & Makarem, 2016), and tend to use more emergency services than a multidisciplinary and continuous health care (Corney, 1990). These reasons may also explain the reduced number of men seeking bariatric surgery treatment for obesity. Despite of these assumptions there is no evidence of men being less willing to search health services or treatments than women (Macintyre, Ford, & Hunt, 1999).

CONCLUSION

Changes in behavior and lifestyle patterns have occurred worldwide in the recent decades, especially regarding to the importance of physical activity and habits of food consumption, which lead to increased risk for the development of a variety of diseases. Currently the incidence and prevalence of obesity, is considered to be the XXI century epidemic (Satia-Abouta, 2003).

All around the world, countries struggle to deal with increasing population overweight and obesity. Understand sex differences and their impact would allow the development of tailored assessments, strategies and interventions pre and post bariatric surgery, requiring specific screening methods to facilitate positive outcomes (Mazzeo et al., 2006).

Bariatric surgery is considered equally safe in men and women (Tymitz et al., 2007). Although all patients should complete a battery of pre surgical exams, and pass through a psychological evaluation to help identify patients at risk for postsurgical psychological or behavioral problems, it is possible to anticipate some sex-specific aspects and present a more efficient service from the counseling view.

Each patient is different and should be considered as such, but from the start women with obesity are biologically in disadvantage, compared to men, regarding weight regulation and also bariatric surgery outcomes. This disadvantage is mainly due to body composition and distribution, muscle capacity and strength for physical exercise, energy homeostasis, pregnancy and menopause. Men undergoing non-surgical treatments and surgical treatments for obesity tend to lose more weight than women. However, men with obesity have more preoperative risk factors, lower comorbidities remission rates, higher postoperative complications and higher risk of mortality. In turn, women with obesity have higher prevalence of eating disorders as well as problematic eating behaviors.

Psychological variables play an important role for both sexes influence all the various aspects of success in bariatric surgery. Pre-operative anxiety, postoperative depression and the presence of both, lead to lower weight loss after surgery and women are the ones with greater probability of reporting a history of such mental disorders. Body image dissatisfaction seems to be prominent in women with extreme obesity, which is considered to be the first reason for undergoing bariatric surgery in women, to improve appearance which is related with body image dissatisfaction. However, the majority of bariatric surgery candidates are dissatisfied with their image. The presence of a traumatic event like sexual abuse, most prevalent in women, is considered to be a psychosocial risk for undergoing bariatric surgery due to the relation with the condition of being obese has in these women.

All of these differences could in parte explain some of the inconsistent results found in previous studies over the treatment of obesity.

This chapter allows the reader to have a complete overview on sex differences in obese and bariatric populations, gathering recent scientific information that supports the clear need for monitoring men and women in health care. Psychological counseling should be considered indispensable for these higher risk population in developing effective strategies, and adjusted interventions to sex-specificities.

It is also important to study future possible bariatric surgery candidates in order to predict and prevent with specialized interventions the increase in obesity and diminish the prevalence of eating disorders, in which sex differences still plays an important role. Other populations

such as adolescents with obesity, who are at increased risk of choosing and reproducing maladaptive behaviors in food consumption and emotional management as seen in the family, peers and role models.

ABSTRACT

Six Sigma and Lean are two prominent quality improvement methodologies that have been validated across several areas of healthcare. Despite a slow initial uptake within the surgical unit, the use of Lean and Six Sigma has increased markedly. The Six Sigma quality improvement methodology, is a data-driven approach developed by the Motorola Corporation that seeks to improve outcomes by eliminating the variation within a process. To date, clinical use of the Six Sigma methodology has focused on efficiency issues, but the application of the Six Sigma method has been used successfully to improve clinical results and to reduce surgical complications in repetitive procedures. Therefore, the use of this methodology in the healthcare arena has focused mainly on areas of business operations, throughput, and case management and has focused on efficiency outcomes.

After the revision of the methodology, the chapter presents a brief clinical example of the use of Lean Six Sigma as a quality improvement method in the reduction of the complications during and after VATS major procedures. Using the Lean Six Sigma methodology, the multidisciplinary teams could identify multiple modifiable points across the surgical process. These process improvements could be applied to different surgical specialities and could result in a measurement, from a statistical point of view, of the surgical quality.

findings could be applied to different surgical specialities and could result in a measurement, from a statistical point of view, of surgical quality.

Keywords: medical statistics, statistical analysis, thoracic surgery, Six Sigma methodology

1. INTRODUCTION

Six Sigma and Lean are two prominent quality improvement methodologies that have been validated across several areas of healthcare. Despite a slow initial uptake within the surgical unit, the use of Lean and Six Sigma has increased noticeably [1].

2. SIX SIGMA IS A QUALITY EVALUATION METHODOLOGY

Six Sigma was developed by the Motorola Corporation in 1986 and aims to improve the quality by identifying and correcting the causes of errors [1]. The Six Sigma approach attempts to drive production failures to six standard deviations (sigma) from the mean or 3.4/1,000,000 defects per products. The term Six Sigma reflects the statistical objective of the approach, namely striving to achieve a negligible number of defects, corresponding to the probability associated with a corrected Six Sigma value for the standard curve. Applying the standard curve, Six Sigma attempts to relegate defects and quality problems to the very tails of the distribution, making such problems rare exceptions in a process that operates almost without defects. The Six Sigma level of performance is not possible in biological systems, but its methodology applies to repetitive procedures. The roots of Six Sigma as a measurement standard can be traced back to Carl Frederick Gauss who introduced the concept of the standard curve. Six Sigma as a measurement standard in product variation can be traced back to 1920 when Walter Shewhart showed that three sigma from the mean is the point where a process requires correction. The Six Sigma methodology has gained wide popularity because it has proven to be successful not only in improving quality but also at producing significant cost savings along with those improvements. As mentioned earlier, to achieve the Six Sigma objective, a process must not produce more than 3.4 defects per million opportunities to produce such defects, where a defect is defined as an unacceptable outcome produced by the process under scrutiny [2].

3. THE LEAN PROCESS STRATEGY

The Lean process strategy is attributed to the Toyota Production System where specific types of manufacturing “waste,” which absorb personnel, resources, or time but do not add value to the overall processor to the end user of the service or product are eliminated. Lean is a process that continually reduces waste and improves workflow to efficiently produce a product or service that is perceived to be of high value to those who use it. The successful application of Lean and Six Sigma management tool is not limited to manufacturing but has been applied to the customer and financial service industries and the government.

Increasingly, Lean and Six Sigma are being used in the healthcare industry. Like other industries, the use of these tools can be applied to several aspects of health care, including finance, inventory management, information processing, outpatient clinics, and inpatient setting [3]. Lean focuses on reducing wasteful or non-value-added steps in a process, and Six Sigma reduces process variation through the application of statistical methods. In many quality improvement projects, these different tools are complementary, which has led to merging them into a single strategy, the Lean Six Sigma methodology [3].

3.1. The Lean Six Sigma Methodology

Recently, in healthcare Lean Six Sigma was used to improve the organisation and quality of care and to reduce costs. Lean Six Sigma offers the roadmap of DMAIC (define, measure, analyse, improve, control) as an improvement methodology and a conceptual organisational framework with specific roles for project leaders and project owners to improve processes. The DMAIC phases are milestones for the improvement project and integrate statistical quality tools and techniques like failure mode and effect analysis and statistical process control. Process and outcome measurements are combined with project metrics into a systematic review process so that that management can deal with the progress of the projects. The five DMAIC phases are [2].

- **Define**
The Define phase of the DMAIC roadmap concerns the definition of the problem to be solved. The project charter determined the project leader, process owners, scope, timeline, and auxiliary members of the project team. To put the problem in perspective, a Supplier, Input, Process, Output, and Customer analyses were made, leading to a detailed flowchart of the process at the micro level. The process leader did a stakeholder analysis, to chart the stakes and the influence of the people involved.
- **Measure**
To quantify the current process performance, we need appropriate measurements, the so-called critical to quality indicators in Lean Six Sigma terms. A critical to quality flow down was used to translate the rationale underlying the project into performance indicators and strategic focal points. The critical to quality flow down resulted in a measurement plan to determine the current performance, the number of clinical intakes and throughput time of the process.
- **Analyse**
The Analyse phase aimed to arrive at a data-based diagnosis of the current process performance.
- **Improve**
After the process was diagnosed, the project team determined objectives for interventions to eliminate waste and to reduce waiting times.
- **Control**
The new process is actively monitored, to assure that better results are retained [4].

The power of Lean Six Sigma lies in its empirical data-driven approach (and its focus on using quantitative measures of how the system is performing) to achieve the goal of process improvement and variation reduction. The distribution of a characteristic in Six Sigma has usually assumed Gaussian for continuous variables and Poissonian for discrete variables. To date, the use of the Lean Six Sigma methodology in the health-care arena has focused mainly on areas of business operations (nurse recruitment), throughput (emergency department and diagnostic radiology wait times), and case management (improvement of test scheduling) [5]. The clinical use of the Lean Six Sigma methodology has focused on efficiency outcomes, such as reducing the length of hospital stay in stroke patients, but the application of the Lean Six Sigma corporate improvement method was successfully used to improve clinical outcomes and to reduce surgical complication in repetitive procedures [2].

A clinical example of the use of Lean Six Sigma as a quality improvement method, developed from previous experience in other specialities [6], can be employed to reduce the complications resulted during and after lobectomies. A surgical team was assembled and trained in the Lean Six Sigma methodology. This team assured committed and consistent leadership to overcome the complications. The surgical team firstly generated a Supplier, Input, Process, Output, and Customer table for surgery process. To achieve the performance objective, the surgical team first determined by brainstorming the critical to quality factors, i.e., the factors that may influence the objective. The surgical team determined the metrics to measure existing process.

The metrics to be chosen for a Six Sigma study were the total number of performed in the unit and the number of complications. Data were collected for a period of x years. In this period, s VATS major procedures were performed on n patients. Complications had been noted as they occurred. The surgical team identified c types of complications and classified them as when (e.g., intraoperatively and/or postoperatively), and how soon they occur (e.g., acute, sub-acute and/or chronic). Then, sources and root-causes of these complications are tabulated by type. To measure the current sigma level of a complication, the surgical team calculated the current defects per million opportunities and sigma levels for each complication type. Normal distribution underlies Six Sigma's statistical assumptions [7].

4. HOW TO CONDUCT A STUDY WITH THE LEAN SIX SIGMA METHODOLOGY?

Lean and Six Sigma are favourite strategies used by leaders in the industry to improve efficiency, quality, and return. Thus, literature offers some recommendations when conducting studies implementing Lean and/or Six Sigma methodologies to improve the quality of the evidence. The training involved staff members in data collection and statistical methods and engage individuals proficient in research methodology. The determination of the study protocol, including the outcomes that will be measured, a priori with the intention of conducting an objective and impartial empirical study should be done. Documenting this initial protocol in the final report reduces the likelihood of selective outcome reporting, subsequently minimising the risk of bias. Measure a diverse set of outcomes that do not only measure the intended benefits of the study should be added. Report all measured outcomes, including adverse outcome(s), in natural units alongside the net cost savings of the project.

Judgments about confidence in effect estimates should be based, as far as possible, on estimates of resource use rather than on estimates of the costs of those resources. Data should be collected in three phases: before, during, and after quality improvement implementation. Measure outcomes for at least one year after study completion to reduce the risk of observational bias and ensure sustainability. A similar period should be followed when collecting data before quality improvement implementation. Avoid uncontrolled before-and-after study designs whenever possible. If randomised trials cannot be conducted, a time-series design is recommended. Measure and compare the final trend of the data to help determine whether improvements are sustainable. Conduct thorough statistical analysis of the data, including calculating P values and 95% confidence intervals for all measured outcomes (wherever practical) to ensure that results are statistically significant and to estimate precision and conduct follow-up studies to further ensure that the results are sustainable [8].

CONCLUSION

Using the Lean Six Sigma methodology, thoracic surgeons could identify multiple modifiable points across the surgical process. Process improvements based on these findings could be applied to different surgical specialties and could result in a measurement, from a statistical point of view of surgical quality.

Chapter 447

MECHANICAL VENTILATION IN PATIENTS AFTER CARDIAC SURGERY

Javier Barrenechea Gutiérrez*,

Pía Antequera Gorrini and Max Varela González

Physical Medicine and Rehabilitation Department and Coronary Intensive Critical Unit,
Clinica Alemana de Santiago, Chile

ABSTRACT

Mechanical ventilation is used to treat patients who undergo procedures and/or surgeries in order to maintain ventilatory support and thus achieve adequate tissue oxygenation and reduce the risk of post-operative complications. In cardiac surgery, the application of ventilatory strategies such as titration of tidal volume, use of moderate PEEP and early extubation protocol is part of the process that takes place in most hospitals.

1. CARDIAC SURGERY AND MECHANICAL VENTILATION

Cardiac surgery has been performed since the middle of the last century, and the use of an extracorporeal circulation system or cardiopulmonary bypass (CPB) is a relevant element considering its impact on the pathophysiology of the surgical process. Mortality in patients undergoing cardiac surgery is less than 2%, with a similar rate of incidence in acute lung injury (ALI) and acute respiratory distress syndrome (ARDS) [1].

This procedure triggers several physiological reactions, including cardiac injury due to the surgical manipulation and a marked systemic inflammatory response, which is triggered by the cardiopulmonary bypass and reperfusion mechanisms during and after surgery [2]. In addition, it can generate some frequent inflammatory processes as a result of the surgery, which can contribute to post-operative complications, such as myocardial dysfunction,

* Corresponding Author's Email: jbarrenecheag@udd.cl.

respiratory failure, renal and hepatic dysfunction, neurological alterations, bleeding and finally a possible multiple organ failure [3].

Cardiopulmonary bypass in cardiac surgery produces profound physiological changes, not only in the circulatory system but also in other systems. Recovery from the physiological homeostasis of these changes can take hours or even days in patients with uncomplicated conditions. For this reason, it is a common practice to keep patients on ventilatory support, sedated until the day after surgery [4].

Pulmonary dysfunctions are among the most common post-operative complications. About 25% of the patients who do not have severe post-operative cardiac dysfunction have some alteration or pulmonary complication for at least one week after surgery [5]. The greatest proportion of this disability is related to CPB, which generally leads to excessive interstitial pulmonary edema resulting in abnormal gas exchange [6] decreased pulmonary compliance and increased intrapulmonary shunt [7].

1.1. Mechanical Ventilation

The main objective of mechanical ventilation during cardiac surgery and after the period in CPB is to ensure optimal oxygenation with adequate CO₂ removal and avoid post-operative pulmonary complications [8].

Mechanical ventilation with the use of increased tidal volume (VT) (10 - 15 mL/kg predicted body weight) has traditionally been recommended to prevent hypoxemia and atelectasis in anesthetized patients. There is, however, considerable evidence from experimental and observational studies that mechanical ventilation, particularly with high tidal volume, causes alveolar overdistension, and may initiate pulmonary-induced injury associated with ventilation [9]. The ARDS Network is one of the studies that generated a break in the programming of mechanical ventilation, this was done in patients with ARDS, in which when comparing use of tidal volume (VT) to 6 mL vs. 12 mL/kg weight, patients with low VT had lower mortality than the group with a high VT [10].

Additionally, the application of alveolar recruitment strategies and positive end-expiratory pressure (PEEP) titration were implemented as useful tools in the treatment of patients with ARDS [9]. Then, Amato et al. brought the importance of measuring the distension pressure or “driving pressure” as a parameter for estimating lung damage into the discussion. They established that a driving pressure lower than 15 cmH₂O reduces mortality in patients with ARDS [11]. Another parameter to be taken into account is the plateau pressure, with the American Thoracic Society consensus recommending a value <30 cmH₂O [12].

In 2010, a randomized controlled trial in patients undergoing invasive mechanical ventilation (IMV) without ARDS compared patients with tidal volume titration of 6 vs. 10 mL/kg predicted body weight. The study showed that the plasma levels of interleukin 6 (IL-6) decrease significantly in patients with low VT. In addition, over the days on IMV the group with VT of 6 mL/Kg predicted body weight had a lower oxygenation index, a lower lung damage score, and from the point of view of pulmonary mechanics had a better static compliance and a lower minute volume on the 4th day on IMV [13].

In 2012 Serpa Neto et al. conducted a review of studies on patients on mechanical ventilation without ARDS, in which titration of the tidal volume close to 6 vs. 10 mL/Kg

predicted weight produced less ventilation-induced pulmonary damage, as well as lower mortality, lower pulmonary infection and a lower degree of atelectasias [14].

All these parameters must be taken into account at the time of titration of mechanical ventilation in post-cardiac surgery patients who do not have ARDS, who generally have healthy lungs, subjected to stress such as surgery.

1.2. Mechanical Ventilation in Cardiac Surgery

Despite the benefits offered by mechanical ventilation in the care of the critical patient, it is not exempt from adverse effects, as this alone can cause damage, in severe ill patients and others of lesser severity who are exposed to prolonged mechanical ventilation, known as ventilation-induced lung injury (VILI). This may indicate that the marked pulmonary dysfunction following cardiac surgery is the result of two noxae that trigger an “insult” to the lungs: 1) the cardiac surgery procedure, with or without CPB and 2) mechanical ventilation to the lung in an inflammatory environment [7]. Mechanical ventilation in patients after cardiac surgery is a short-term process, depending on the severity of the patient’s condition, and may be between 4 and 8 hours, but it is not necessary to stop applying protocols and maintain “protective ventilation parameters” used in critically ill patients as in ARDS to avoid VILI.

Protective mechanical ventilation in patients undergoing cardiac surgery is not limited to the reduction of tidal volume. It involves an assisted-controlled ventilatory technique, with a low tidal volume (6-8 mL/Kg predicted weight), associated with high PEEP and the limitation of the inspired oxygen fraction. This programming is maintained during cardiopulmonary bypass and to which alveolar recruitment maneuvers can be added, thus being the major components of ventilatory management in patients after cardiac surgery [8].

In 2000 Chaney et al. published one of the first articles related to protective mechanical ventilation in patients undergoing cardiac surgery, and determined that pulmonary mechanic parameters were reduced in airway pressures, both plateau and peak. Furthermore, titration of the tidal volume would attenuate pulmonary dysfunctions such as decreased compliance and increased intrapulmonary shunt, commonly seen in patients after exposure to cardiopulmonary bypass [15].

Lellouche et al. conducted a prospective study on patients after cardiac surgery and analyzed the association between high tidal volume and some organic dysfunction (prolonged mechanical ventilation, hemodynamic instability and renal failure), in addition to prolonged stay in the intensive care unit. Patients in the group with the highest tidal volume had the longest time on mechanical ventilation (7.4 vs.6.0 hours in group <10 mL), renal failure and longer stay in the intensive care unit. In addition, they found that obesity (BMI> 30) and being female were risk factors at the time of setting the mechanical ventilation. This may be due to the fact that a higher VT is frequently programmed in these patients [16].

In relation to the inflammatory response at the systemic level in patients undergoing surgery, Zupancich et al. studied the effects of high VT and low PEEP vs. low VT and high PEEP. With respect to the inflammation process, after 6 hours in invasive mechanical ventilation the concentrations of interleukin-6 (IL-6) and interleukin-8 (IL-8) were higher in the group of patients with high VT and low PEEP. From the point of view of pulmonary mechanics, the group of patients treated with low VT and high PEEP presented lower plateau pressures and minute volume [17].

The study conducted by Sundar et al. in 2011 compared the time to extubation in patients undergoing cardiac surgery with protective ventilation and limitation of the VT at 6 vs. 10 mL/kg predicted weight. A higher proportion of patients with protective ventilation was out of mechanical ventilation at 6 hours after surgery (37.3 vs. 20.3%) and also after 8 hours (53.3 vs. 31.1% in control group) [1].

1.3. Post-Operative Alveolar Recruitment

Pulmonary dysfunction after cardiac surgery is a constant. Its appearance increases the occurrence of respiratory complications and delays rehabilitation. It is for this reason that ventilatory strategies have been proposed that seek to reduce, as far as possible, these respiratory complications. Further on in this chapter, we will analyze how the presence of PEEP can prevent alterations in tissue oxygenation. Likewise, the use of small periods of high inspiratory pressures to open the collapsed alveolus, followed by a relatively high level of PEEP to keep it open associated with a low level of tidal volume, seems able to accelerate lung function recovery [18].

In the post-operative period of cardiac surgery, the use of PEEP of 5 cmH₂O and the decrease in VT can lead to hypoxemia due to atelectasis, which in the case of this surgery is approximately 6 times more frequent than for abdominal surgery [19]. When the tidal volume is decreased, atelectasis can be prevented with the implementation of PEEP slightly higher than 5 cmH₂O (8 to 12 cmH₂O), particularly in obese patients with reduced thoracic compliance [8].

It is important to prevent atelectasis because the recurrence of cyclic alveolar opening in inspiration and closure in expiration caused by the presence of atelectasis is among the major causes of lung inflammation and ventilation-induced damage [7, 20].

Positive end-expiratory pressure (PEEP) aids in preventing alveolar collapse and the consequent formation of atelectasis, but it also generates hemodynamic changes that are important to consider when setting the PEEP. Ventilation with positive pressure restricts the filling of the right ventricle by an increase in intrathoracic pressure, restricting venous return to the thorax and thereby reducing cardiac output. As the heart rate does not change with PEEP, the drop in systemic cardiac output is then a result of the reduction in left ventricular stroke volume. Therefore, the discussion of the change in PEEP-induced cardiac output should be analyzed for changes in stroke volume and its determinants: preload, afterload, contractility and ventricular compliance [21].

The concept of “open lung”, which involves the application of small periods of high inspiratory pressure to open the collapsed alveolus associated with a relatively high PEEP to keep the alveolus open and low VT, is one of the strategies used in patients undergoing cardiac surgery with and without extracorporeal circulation. Bolzan et al. showed that patients with both early (immediately after intubation) and late (30 minutes after arrival to an ICU) open lung had better results in lung function, higher value in forced vital capacity (FVC) and forced expiratory volume in the first second (FEV1), than those subjected to conventional ventilation. In relation to functional capacity measured through the 6-minute walk test, the group with early open lung was significantly higher than in the late open lung group, and this was significantly higher than the conventional ventilation group in terms of meters walked in the preoperative evaluation [22].

The use of alveolar recruitment is a widely implemented technique in patients with ARDS; however, it is also applicable in patients undergoing cardiac surgery. A randomized study on patients undergoing cardiac surgery without extracorporeal circulation (off-pump), separated into 3 groups: i) conventional ventilation (VT 8 mL/Kg ideal weight, PEEP 0 in operating room and PEEP 5 in ICU piece), ii) late open lung (tidal volume 6 mL/Kg ideal weight, PEEP 10) with increase in re-expansion maneuvers reaching inspiratory peak pressures of 40 cmH₂O for 15 seconds and iii) early open lung, with post-intubation beginning with re-expansion maneuvers with inspiratory pressures peak of 40 cmH₂O (tidal volume 6 mL/Kg ideal weight and PEEP 10), reducing the PEEP to 5 if it made the process of bypass surgery difficult. The lung capacity results measured by spirometry on days 1, 3 and 5 indicated that patients undergoing early and late open lung had better results in forced vital capacity (FVC) and forced expiratory volume in one second (FEV₁) on days 1, 3 and 5 than the conventional ventilation group [18].

A similar study carried out in 2005 by Miranda et al. in which alveolar recruitment was applied to an early open lung group, another late open lung group and a third group with conventional therapy. The application according to the open lung ventilation concept was associated with a greater post-operative functional residual capacity than that obtained with conventional ventilation [23].

A study has also reported on patients with hypoxemia after cardiac surgery, subject to titration of the tidal volume at 6 mL/kg ideal weight. They were divided into groups with intensive recruitment strategy and moderate recruitment strategy. The intensive recruitment group received 3 cycles of inflation (60 seconds) in pressure control mode with PEEP 30 cmH₂O and driving pressure of 15 cmH₂O, with a respiratory rate (RR) of 15x', and then the PEEP was lowered to 13 cmH₂O, driving pressure to achieve 6 mL/Kg ideal weight of tidal volume and RR to maintain PaCO₂ between 35 and 45 mmHg. Patients in the moderate recruitment strategy group received 3 cycles followed by 30 seconds with CPAP 20 cmH₂O and subsequently ventilation with volume control mode PEEP 8; VT of 6 mL/kg ideal weight, RR to maintain PaCO₂ between 35 and 45 mmHg. Patients under intensive recruitment had fewer points on the pulmonary complications score. The occurrence and severity of post-operative complications in the intensive recruitment group was lower than in the moderate recruitment group. In addition, the intensive recruitment group had fewer days of stay in the ICU and days of hospitalization. In terms of mechanical and arterial gases, the intensive recruitment group had a better PaO₂:FiO₂ ratio, better pulmonary compliance and lower driving pressure than the other groups [24].

Lago Borges et al. compared the use of PEEP in 3 groups, PEEP in 5, 8 and 10 cmH₂O, with a tidal volume between 6 to 8 mL/Kg ideal weight. The group with PEEP 10 had better lung compliance and lower airway resistance (although with no statistically significant difference), increasing oxygenation and decreasing the occurrence of hypoxemia [25].

Dongelmans et al. compared the use of PEEP of 10 cmH₂O vs. 5 cmH₂O (both groups with VT between 6 - 8 mL/kg ideal weight) in the period following cardiac surgery. The group of patients with high PEEP presented better pulmonary compliance and better oxygenation than the group with low PEEP, but this did not reduce the time to extubation, caused by an increase in the time of use of propofol for sedation [26].

2. EXTUBATION AND THE FAST-TRACK PROCESS

To perform early extubation or fast-tracking, a multidisciplinary team is required as well as a consolidated process with assessment tools and goals to be met in the post-operative period so as to reduce errors and make the right decisions when extubating the patient.

The “fast-track” process began in the early 1990s; it has no standard definition but usually aims to extubate the patient within 6-8 hours after surgery [27], and involves several components of care during cardiac anesthesia and in the post-operative period. The ultimate goal is early post-operative extubation, which may reduce the days of stay in the intensive care unit and in the hospital [28] and possibly decrease the rate of ventilator-related pneumonia [29].

In 2016 Cove et al. published an article detailing the early extubation process carried out in the surgical center. Carrying out the fast-track process with a multidisciplinary team managed to reduce the time to extubation by 35% in a study group compared to the patients in their own institution who underwent surgery prior to application of the protocol. In addition, the mechanical ventilation time was reduced by 24% in the pressure support mode as were the days of stay in the ICU [30].

Bansal et al. performed a retrospective review of their patients undergoing fast-track extubation, taking 7.3 hours as the cut-off time. Those who spent less time on mechanical ventilation had fewer ICU days and hospital days [29].

Reyes et al. implemented a protocol with patients for early extubation (between 7 and 11 post-operative hours) and a control group with conventional management who extubated the morning after the day of surgery. In the early extubation group, the average time to extubation was 8.52 hours compared to 19 hours in the conventional group [4].

In 2014, Probst et al. conducted a study on post-operative management and the time of early extubation between a post-anesthetic care unit (PACU) and the ICU. Both presented the same criteria for extubation. The median extubation in the PACU was 90 min vs. 478 min in the ICU. One of the important differences was that in the PACU, the nurse-patient and therapist-patient relationships were both 1:3, with the therapist being an anesthetist, whereas in the ICU the nurse-patient relationship was 1:2 and therapist 1:12 [31]. The development of the PACU as a place for post-operative work has better results if it has limited hours (12 vs. 24 hours), since in limited hours the intubation times are shortened, the stays in intermediate units are shortened and costs are reduced, unlike a PACU with unlimited hours (24 hours) [27].

A review by Wong et al. compared the fast-track and the conventional therapy groups. The results showed that the group with a low dose vs. a high dose of analgesia had no significant differences in post-operative complications such as myocardial infarction, cerebrovascular accident and re-intubation, nor did the groups associated with time-directed extubation protocols after surgery. In addition, the fast-track process associated with a low dose of analgesia decreases mechanical ventilation times (4.3 vs. 10.5 h), and the same occurs with the groups associated with the post-operative time-directed extubation protocol (3.7 vs. 8.8 h). Furthermore, mechanical ventilation times and days of stay in the ICU are reduced [28, 30, 32, 33].

On the other hand, there is a range of patients who are not candidates for a fast-track process, such as those who underwent a cardiogenic shock, dialysis-dependent patients, or

who have a Euroscore greater than 10 [31]. Those with previous risk factors such as ejection fraction <35%, pre-operative or post-operative cardiac assist devices and post-operative cardiopulmonary instability (high inotropic support, lactate > 5 mmol/L, Horowitz Index under 200) [34, 35]. In addition, there are independent risk factors that can cause the fast-track process to fail, such as those patients over 70 years of age, duration of surgery, cross-clamp time and being female [36].

2.1. Fast-Track Inclusion Criteria

- Elective surgeries [36]
- Hemodynamically stable (SBP > 90 mmHg, HR <120 bpm, adrenaline or noradrenaline < 0.04 mcg/kg/min), T° > 36°C, without bleeding [31, 36].

The requirements to perform extubation depend on the protocol that exists in each unit, but generally there are 3 aspects to consider: hemodynamic, respiratory and neurological stability.

Figure 1. Proposal for mechanical ventilation management of patients after cardiac surgery.

Hemodynamic stability presents without uncontrolled arrhythmias, normal electrocardiogram, bleeding drains <100 mL/hour and a $T^{\circ} \geq 36^{\circ}\text{C}$. From the neurological point of view, the patient must cooperate and follow indications, without neurological deficit (Ramsay Sedation Scale2, SAS 4). From the respiratory point of view, the patient must have a spontaneous respiratory rate between 10-20 resp/min, $\text{FiO}_2 < 40\%$, acceptable blood gases ($\text{PaO}_2 \geq 100 \text{ mmHg}$, $\text{PaCO}_2 \leq 40 \text{ mmHg}$), PEEP 5 with inspiratory support pressure 5 to 10 cmH₂O for a time of at least 30 minutes, normal lactate and normal chest radiograph [26, 36].

In addition, one should be alert to the possible spontaneous ventilation test failure criteria, such as the pulse >20 bpm > pre-wean rate for >5 minutes, respiratory rate ≤ 7 or ≥ 35 for 5 minutes, $\text{SatO}_2 < 92\%$ or $\text{PaO}_2 < 60 \text{ mmHg}$ for more than 5 minutes, marked use of accessory muscle and/or abdominal paradox, marked distress, subjective dyspnea or agitation, arrhythmias on the ECG or chest pain [37].

CONCLUSION

Mechanical ventilation in patients after cardiac surgery is a complex process which must be undertaken by a multidisciplinary team and with an established protocol to assist in rehabilitation. The mechanical ventilation techniques and modes used in critical patients are also tools used after cardiac surgery. Titration of the tidal volume (6 - 8 mL/Kg ideal weight), application of alveolar recruitment protocols, use of ideal PEEP in relation to pulmonary mechanics and an established fast-track protocol comprise the ideal process to be applied in patients after cardiac surgery. The application of these concepts reduces the times in mechanical ventilation, days of stay in the ICU and days of hospitalization, aiding in a faster and more efficient rehabilitation of patients.

Chapter 448

IMPROVEMENT OF CARDIOVASCULAR RISK FACTORS AFTER BARIATRIC SURGERY

Jaime Ruiz-Tovar¹ and Carolina Llaverro²

¹Department of Surgery, Centro de Excelencia para el Estudio y
Tratamiento de la Obesidad, Valladolid, Spain

²Department of Surgical Nursery, Hospital del Sureste, Madrid, Spain

ABSTRACT

Impaired glucose tolerance, hypertension, and dyslipidemia have been described as metabolic syndrome (MetS). MetS is associated with an increased cardiovascular risk. A close association between morbid obesity and MetS has been highlighted in several clinical studies. Disease risk increases with increasing body mass index (BMI). However, BMI can be misleading for certain body constitutions. Thus, other parameters have been proposed as predictors of cardiovascular risk. Among them, the adiposity, the Framingham Index and the Atherogenic Index (Triglycerids/HDL-c.).

Bariatric surgery has been shown to be effective in achieving and maintaining weight change and reducing obesity-related comorbidities. Malabsorptive procedures (biliopancreatic diversion and duodenal switch) have been associated with the greatest reduction of cardiovascular risk, associated with a greatest improvement in obesity-related comorbidities (diabetes mellitus, hypertension and dyslipidemia). On the other hand, the lowest improvement is obtained after restrictive procedures (Adjustable gastric banding (AGB)). However, despite sleeve gastrectomy is also considered a restrictive procedure, the reported improvement of cardiovascular risk reduction is greater than after AGB, as a certain hormonal effect is also involved in this technique-

In this chapter we will review the current evidence of obesity-related comorbidities and cardiovascular risk factor index after different bariatric approaches.

INTRODUCTION

More than 2/3 of the U.S. population is overweight or obese. Obesity is on the rise and the incidence is increasing most rapidly in the morbidly obese population, i.e., those with

BMI exceeding 40 kg/m². Epidemiological studies estimate the prevalence of morbid obesity around 0.5%, but this rate is probably underestimated, as many morbidly obese subjects are not under any medical control. Only surgery results in substantial, long-term weight loss for obese individuals. Therefore, the performance of bariatric procedure has increased exponentially in the last 2 decades; from less than 9,000 procedures in 1993 to a high of over 115,000 in 2004. It is estimated that 220,000 weight-loss surgeries were performed in 2008. Actually, the number of bariatric procedures performed is even higher [1].

Impaired glucose tolerance, hypertension, and dyslipidemia have been described as metabolic syndrome (MetS). MetS is associated with an increased cardiovascular risk. A close association between morbid obesity and MetS has been highlighted in several clinical studies. Disease risk increases with increasing body mass index (BMI) [2].

Bariatric surgery has been shown to be effective in achieving and maintaining weight change and reducing obesity-related comorbidities. Malabsorptive procedures (biliopancreatic diversion and duodenal switch) have been associated with the greatest reduction of cardiovascular risk, associated with a greatest improvement in obesity-related comorbidities (diabetes mellitus, hypertension and dyslipidemia). On the other hand, the lowest improvement is obtained after restrictive procedures (Adjustable gastric banding (AGB)). Despite sleeve gastrectomy is also considered a restrictive procedure, the reported improvement of cardiovascular risk reduction is greater than after AGB. It has been hypothesized that a certain hormonal effect is also involved in this technique [3].

Disease risk increases with increasing body mass index (BMI). However, BMI can be misleading for certain body constitutions. Thus, other parameters have been proposed as predictors of cardiovascular risk. Among them, the adiposity, the Framingham Index and the Atherogenic Index (Triglycerids/HDL-c.) [2, 4].

Diabetes Mellitus

Bariatric surgical procedures are effective interventions for treating type 2 diabetes. Improvement in metabolic control is often evident within days to weeks following bariatric procedures, most likely reflecting an alteration in metabolism that is independent of weight loss [5].

Three randomized trials illustrate the efficacy of weight loss surgery versus medical therapy alone:

- Obese patients with uncontrolled type II diabetes, undergoing a RYGB or a SG plus medical therapy, were significantly more likely to achieve the main outcome of a glycated hemoglobin level of 6% or less at 12 months, compared with patients managed by intensive medical therapy alone (42% versus 37% versus 12%, respectively) [6].
- A randomized trial of 60 patients also found that obese diabetic patients undergoing a bariatric operation had better control than medical management alone. Obese patients (BMI ≥ 35) with a history of diabetes for five or more years and a glycated hemoglobin level $\geq 7\%$, undergoing a RYGB or biliopancreatic diversion (BPD), were significantly more likely to achieve the study endpoint of remission of diabetes

at two years, compared with patients managed by medical therapy alone (75% versus 95% versus 0%, respectively) [7].

- A randomized trial that included 120 patients demonstrated that a RYGB procedure was superior to intensive medical management alone in achieving the main outcome measure of a glycated hemoglobin level of less than 7%. (75% versus 32%) [8]. Results following RYGB operation are promising and several trials are in progress to evaluate the procedure for patients with BMI <35 and poorly controlled type 2 diabetes [9, 10]. Efficacious control of type 2 diabetes has also been demonstrated following a SG or an AGB.

In 2011, the American College of Surgeons Bariatric Surgery Center Network (ACSBSCN) found that the remission or improvement was for patients undergoing RYGB, SG, and AGB. In a prospective, longitudinal study, that included bariatric-specific data from more than 100 participating institutions and 28,616 obese diabetic patients, remission or improvement in diabetes at 12 months was achieved in 83% of patients undergoing a RYGB, 55% undergoing SG, and 44% undergoing an AGB [11]. This result has been corroborated by other studies demonstrating one-year remission or improvement of diabetes in 40% to 75% of patients who underwent a SG or an AGB [12, 13]. SG is an alternative procedure to RYGB for patients with BMI <50, the extremes of ages, and smokers.

In addition to glycemic control, improvement in distal peripheral neuropathy was identified following RYGB. An improvement or normalization of the Neuropathy Symptom Score (NSS) and the Neuropathy Deficit Score (NDS) in all patients has been found [14].

Hypertension

The association between obesity and the development of hypertension is well established. Weight loss, whether by an intensive lifestyle-medical modification program or by a bariatric operation, improves obesity-linked hypertension or contributes to remission. Patients undergoing a bariatric surgery plus intensive lifestyle medical management were able to achieve a similar reduction in systolic blood pressure at 12 months compared with patients managed with lifestyle medical modification alone [15]. While intensive lifestyle modification resulting in weight loss appears beneficial for resolution of hypertension, this is unfortunately not feasible for all patients, due to reasons such as lack of motivation or inability to exercise.

Data are unclear as to whether or not RYGB offers the highest resolution or reduction of hypertension of bariatric operations, as illustrated by several studies [16].

Dyslipidemia

Obesity-linked dyslipidemia is a well-established risk factor for cardiovascular disease [17]. The most commonly encountered dyslipidemias in obese individuals include hypertriglyceridemia, decreased HDL-cholesterol values, and increased LDL-cholesterol particles [18]. Multiple studies have demonstrated improved lipid profiles following bariatric

procedures. The most extensively studied procedure is the RYGB. Mean total cholesterol levels decreased by 16%, triglyceride levels decreased by 63%, LDL-cholesterol levels decreased by 31%, total cholesterol/HDL-cholesterol risk ratio decreased by 60%, and HDL-cholesterol levels increased by 39%. In addition, over 80% of patients requiring lipid lowering medications preoperatively, no longer required medical therapy [19]. Malabsorptive procedures obtain at least similar results of improvement of dyslipidemia. A recent study of our group has demonstrated that after SG, HDL-cholesterol values increase and Triglycerides levels decreased significantly. However, total and LDL-cholesterol remained unaltered of present nonsignificant improvements. Notwithstanding, mainly based on the HDL-cholesterol increase, the cardiovascular risk index present a significant improvement after surgery [2].

PREDICTIVE MARKERS OF OBESITY AND CARDIOVASCULAR DISEASE IN MORBIDLY OBESE PATIENTS

BMI and Adiposity

In the 19th century, Adolphe Quetelet observed that the relative weight of the human was proportional to the square of the height. This relation was denominated Quetelet Index and later on, Body Mass Index (BMI) [20, 21]. The cut-off points of the BMI are very useful for epidemiological studies, but it does not represent an accurate measure of the body composition. Frequently, it underestimates obese subjects as just overweight ones. Based on a study performed on more than 6.000 subjects, investigators of the University Clinic of Navarra (Spain) developed an equation to calculate the body fat percentage, also known as adiposity, without depending on sophisticated technology and just based on anthropometric values easily obtained [22, 23]. The new formula, also known as CUN-BAE (Clínica Universidad de Navarra-Body Adiposity Estimator) is an approach to the fat composition and classifies it according previously established ranges. With this new classification, it has been demonstrated that subjects considered as lean or with overweight ($BMI < 30 \text{ Kg/m}^2$) in reality present elevated adiposity ranges, which might explain certain comorbidities associated with the metabolic syndrome [22].

Several studies have analyzed the impact of adiposity on cardiovascular risk, realizing that BMI associated or not to the waist circumference is less effective than adiposity determination [23, 24]. However, the actual devices to measure adiposity (bioelectric impedance, hydrostatic weight, pletismography, double-energy X-ray absorciometry, ...) are often not available in all media, the measures are estimative and imply elevated sanitary costs [25, 26].

CUN-BAE formula has exposed that nearly one third of subjects classified as lean by the BMI, present an elevated adiposity, and 80% of patients classified as overweight, are really obese ones [22-24].

Thus, BMI does not define the obesity grade as an excess of adiposity, but a weight excess, without discriminating between fat, water and muscle. Despite BMI and adiposity present a certain degree of correlation, it is only moderate in morbidly obese patients before undergoing bariatric surgery and slightly increases in postoperative determinations. The

effectiveness of bariatric surgery is not just limited to the reduction of body adiposity, but, when achieving it, the risk of suffering a cardiovascular event is also reduced [27].

Framingham Score and Castelli Index

In our medium, there are two indices, predictive of cardiovascular risk: Triglycerids/HDL-cholesterol (TG/HDL) ratio (Castelli Index) and the Framingham score, which analyzes age, gender, total cholesterol, HDL-cholesterol, tobacco habit and systolic arterial pressure. It has been considered that Framingham score is the most accurate method to calculate the cardiovascular risk, but its application is more complex than other scores [27]. Therefore, the TG/HDL index is preferred by many clinicians, as it can be numerically quantified and is not expressed as the probability of suffering a cardiovascular event, like the Framingham score. Diverse studies have shown that a TG/HDL index >3 is associated with increased cardiovascular risk. A previous study of our group has demonstrated that TG/HDL index correlates with the adiposity grade before and after bariatric surgery, but it does not correlate with BMI at any state. This reflects that both, adiposity and TG/HDL index, are better predictors of cardiovascular risk than BMI [4, 28, 29].

Serum Cortisol

Cortisol plays a role in the adiposity and finally in obesity development. Circulating serum levels of cortisol are higher among obese subjects with or without metabolic syndrome, than in lean ones. Cortisol induces the differentiation and proliferation of human adipocytes and their receptors are more profuse in the visceral adipose tissue than in the subcutaneous one. Moreover, cortisol contributes to the distribution of the fat from the peripheral depots to the central ones; it activates lipolysis and the release of free fatty acids to the blood circulation, increasing the risk of atheromatosis and consequently, the cardiovascular risk.

Weight loss reduces the serum cortisol levels down to normal ranges. According to this, cortisol levels might be considered as reflection of cardiovascular disease. Previous studies of our group demonstrated that the decrease in the adiposity directly correlates with the reduction in the cortisol levels. From the 6th month, the decrease in serum cortisol correlates with a reduction in the cardiovascular risk [2, 4, 30, 31]. All these data confirm the hypothesis that cortisol is an accurate predictor of cardiovascular risk in morbidly obese patients undergoing bariatric surgery.

Vitamin D

In the last decade, actions of vitamin D different than those related with the bone metabolism, have been discovered. These actions have been denominated as non-calcemic actions. These findings demonstrate that vitamin D has diverse functions, corresponding to a hormone rather than an inert vitamin [32, 33].

Deficiencies in vitamin D in obese patients are associated with metabolic syndrome and disorders in lipid levels (cholesterol and triglycerids). This suggests that vitamin D is a

modifiable factor amenable for correction, which may imply a benefit in the cardiovascular risk of these patients [30].

Vitamin D stores mostly in the adipose tissue in obese patients, leading often to a secondary hyperparathyroidism. As they lose weight, the serum values of vitamin D increase. This explains the inverse correlation between the adiposity reduction and the increase of plasmatic levels of vitamin D after bariatric surgery [30].

ABSTRACT

In recent decades, obesity levels have increased worldwide, increasing the prevalence of morbid obesity. This type of obesity is associated with a large number of comorbidities that increase the mortality risk of the patients who suffer it. Therefore, it is necessary to apply a treatment to this type of population. Bariatric surgery has proven to be an effective method, generating large weight reductions and improving cardiovascular risk factors, thus increasing the life expectancy of patients who undergo it. However, this surgery has certain disadvantages. On the one hand, some factors, such as total weight, comorbidities associated with obesity or low cardiorespiratory fitness, are associated with a greater number of surgical complications and a higher rate of intra and postoperative mortality. On the other hand, one of the most common problems after surgery is the weight regain, which is associated with a relapse in different comorbidities, such as diabetes mellitus.

Physical activity has been proved to be an effective tool for reducing total weight and improving cardiovascular risk factors and cardiorespiratory fitness, which can reduce the incidence of these surgical complications. In addition, the performance of physical activity after surgery enhances its effects, generating greater reductions in total weight and cardiovascular risk factors. Furthermore, physical activity has shown to be a factor of great importance for weight maintenance, and, therefore, can be a key point to avoid recurrences in different comorbidities. Although cardiorespiratory exercise at low and moderate intensities has been classically recommended for weight loss, this trend is currently changing. In recent years, several studies have determined that performing exercise at high intensities, adding resistance training to an exercise program, generates greater losses of fat mass and reductions in cardiovascular risk factors compared to traditional recommendations.

1. INTRODUCTION

Definition of Obesity, Resting Metabolic Rate and Body Tissues

Obesity is defined as an excess of fat mass that is associated with high risks for health [1]. This excess of fat mass occurs due to a prolonged state under a positive energy balance, that is, when energy intake is greater than daily energy expenditure. There are 3 components that will determine this daily energy expenditure [2]:

- 1. *Thermic effect of feeding*: this concept refers to the energy expenditure that is produced by the ingestion of food. It is the energy consumed in digesting, absorbing, using and storing nutrients [3]. This energy cost is different for each macronutrient, being very low for fats (0-3%), medium for carbohydrates (5-10%) and higher for proteins (20-30%) (4). It contributes around 10% to the daily energy expenditure [2].
- 2. *Thermic effect of activity*: refers to the energy consumed due to physical activity (PA), therefore, it is a factor that varies greatly depending on individuals. It is especially important, because it is directly related to the activity performed, hence it has influence the basal metabolic rate (RMR). For example, PA can increase the FFM, in this way generates an increase in the RMR [5]. It has been reported that this component contributes between 15-30% to daily energy expenditure [2].
- 3. *Resting metabolic rate*: is the energy consumed by the body for maintaining physiological functions (body temperature, breathing, and other vital functions). It can be a key factor in controlling obesity, since it is the component that contributes the most to daily energy expenditure (60-75%) [2]. It is mainly determined by the FFM [6].

Abbreviations: RMR, resting metabolic rate; FFM, fat free mass.

Figure 1. Distribution of body tissues and contribution of each tissue to the resting metabolic rate. Adapted from Dullo et al. [11].

Figure 2. Skeletal muscle metabolism in patients with morbid obesity. Adapted of Kelley et al. [229].

The body is integrated of different tissues. It is distinguished between adipose tissue and fat-free mass, which is composed by organs, other tissues such as skin or bones, and skeletal muscle (Figure 1). The latter is of great importance, and in recent decades has been recognized as a powerful endocrine organ [7, 8]. Among other aspects, skeletal muscle is responsible for eliminating approximately 75% of glucose after meal [9], and has an important storage function, since 80% of the body's glycogen is stored in it [10]. On the other hand, it consumes a large amount of energy at rest, about 22% of the RMR [11], which comes mainly from the oxidation of fatty acids [12]. However, in obese patients, especially in subjects with morbid obesity, it has been seen that those functions are damaged, and they are metabolically inflexible. That is, during fasting they have a low capacity to fat oxidation, which can be 58% lower than in lean subjects [13], and in a postprandial state have a lower oxidation of glucose. This will cause greater insulin resistance, storage of triglycerides in the muscle and accumulation of fat mass (Figure 2) [9, 14].

Obesity Prevalence

Progress has led to changes in society that have generated an obesogenic environment. On the one hand, the mechanization of industries and the emergence of computers have contributed to a decrease in PA at work, and an increase in sedentary jobs [15]. In addition, new forms of leisure and transportation have appeared, which are more sedentary, such as the television or the use of the car. All this causes that the levels of PA of the population have greatly decreased. For example, in the United States, PA levels decreased from 235.2 MET-hours/week in 1965 to 159.5 MET-hours/week in 2009 [16]. On the other hand, economic development and global trade liberalization have provoked changes in dietary patterns [17], where the “Western diet” has been imposed, which is a type of diet characterized by high intake of fat, added sugars, refined carbohydrates and animal-source foods [18]. In addition, energy intake in the world has increased from 2358 Kcal/day/capita to 2803 Kcal/day/capita between 1964 and 1999 [19].

These factors have led to the fact that, in recent decades, obesity levels have increased greatly in all regions of the world [20, 21].

From 572 million people with overweight or obesity in 1980, it has been estimated an increase to 1.46 billion in 2008, of which 508 million were obese [22]. While other studies concluded that in 2015 there were 603.7 million people with obesity [23]. And the forecasts are not positive, if the trend continues, it is estimated that in the year 2030, 57.8% of the world population will suffer from obesity or overweight, and 19.7% will be obese [24].

However, the problem is even greater, since levels of morbid obesity (Body Mass Index (BMI) $\geq 40 \text{ kg}\cdot\text{m}^{-2}$) are also increasing acutely. Different countries show relative raises in morbid obesity of between 33-200% [25–27]. For instance, in Australia, morbid obesity increased from 1.4% to 3.1% between 1995 and 2012 [28], in Canada, it increased from 0.3% registered in 1985 to 1.6% in 2011 [29], while in the United States this increase was from 0.9% to 3.5% between 1990 and 2008 [30]. It is estimated that, if this trend continues, morbid obesity will affect 6% of men and 9% of women of the world's population in the year 2025 [31].

These high levels of obesity generate great health risks. It has been widely reported that excess weight is a determining factor in the development of type 2 diabetes mellitus [32], hypertension [33], hyperlipidemia [34] and cardiovascular risk [35]. Particularly, above all, this risk is greater with a higher BMI. Subjects with a BMI greater than $35 \text{ kg}\cdot\text{m}^{-2}$ have a risk 42.1 times higher than subjects with a normal weight [36]. Furthermore, 51.3% of subjects with morbid obesity suffer from hypertension, meanwhile 62.5% suffer from dyslipidemia [34]. All these factors contribute to the fact that obesity is directly associated with mortality (Figure 3) [37, 38]. Indeed, a high BMI caused 4 million deaths worldwide in 2015, of which, about 70% were due to cardiovascular disease [23]. In addition, the risk of mortality increases with the BMI, with a hazard ratio of 1.45 for class I obesity and 2.76 for class III obesity [39].

Abbreviations: CVD, cardiovascular disease; NAFLD, nonalcoholic fatty liver disease; HTN, hypertension; T2DM, type 2 diabetes mellitus.

Figure 3. Most common health consequences caused by obesity.

These aspects show the need to reduce the obesity levels of the population. Normally, through of the use of drugs, diet and PA, reductions in the body weight of obese patients are achieved [40]. But in extreme cases, such as morbid obesity, sometimes these methods are not enough [41], and an effective alternative is bariatric surgery (BS).

Bariatric Surgery

Bariatric surgery is a surgical procedure that consists of a reduction in the capacity of food intake (intragastric balloon, vertical banded gastroplasty etc.), a decrease in the absorption capacity of nutrients (biliopancreatic diversion), or well, in a combination of both (gastric bypass) [42, 43]. This surgery is performed on individuals with a BMI ≥ 40 kg·m⁻² or whit a BMI ≥ 35 kg·m⁻² associated with some comorbidity, such as diabetes, hypertension or obstructive sleep apnea (OSA) [44].

The first surgery was performed in Sweden in 1952, by Viktor Henrikson, and it was malabsorptive type [45]. This was followed by a process of development of the surgery, giving rise to the first mixed surgery (gastric bypass) in 1966, and to the first restrictive surgery in 1971, both performed by Edward E. Mason [46]. From this point, BS has evolved, until now it is considered one of the most effective treatments for morbid obesity [47]. In fact, in recent decades, the number of surgeries has increased in parallel with the increase of morbid obesity. In only 16 years (between 1997-2013) the number of surgeries has raised from 40,000 to 468,609 worldwide (Figure 4) [47]. Currently, of all these surgeries performed, the most frequently performed surgical techniques are sleeve gastrectomy and gastric bypass [47], the latter being considered the gold standard of surgery for obesity [48].

Figure 4. Evolution bariatric surgery.

Sarcopenic Obesity

Sarcopenic obesity refers to a disproportion between the amount of lean mass and fat mass, in which the fat mass exceeds the weight that lean mass could support [49]. It has a multifactorial origin. On the one hand, sarcopenic obesity is reached when the total weight is increased at the expense of an increase in fat mass. On the other hand, it is reached when, for example, subjects with morbid obesity lose a large amount of weight, with a large decrease in FFM, but they are still obese subjects [50], which is common in bariatric patients.

This sarcopenic obesity causes certain disadvantages. On the one hand, subjects with sarcopenic obesity may have impaired functional capacity [49]. On the other hand, the loss of FFM can lead to a decrease in the RMR, and therefore, induce an increase in fat mass [51]. Last, sarcopenic obesity influences in the cardiometabolic health of the patients. Subjects suffering from sarcopenic obesity have higher levels of blood pressure and greater insulin resistance than subjects with obesity or sarcopenia, as well as an increased risk of developing diabetes mellitus [52, 53]. As a result of all this, sarcopenic obesity increases the risk of suffering cardiovascular disease and mortality risk, which is higher compared to subjects who are only obese or sarcopenic [52, 54, 55].

2. EXERCISE BEFORE BARIATRIC SURGERY

Cardiovascular Risk Factors and Operative Complications

Normally, patients who are waiting for BS usually suffer from different comorbidities. Among others, it has been reported that 34-54.9% suffer from hypertension, 22-44.8% of OSA, 18-33.7% have type 2 diabetes mellitus and 7.4-50.2% of dyslipidemia [56–58]. On the one hand, this comorbidities such as hypertension, diabetes and hyperlipidemia are associated with mortality at 30 days after surgery [59–61]. On the other hand, these contribute to increase the risk of suffering post-operative complications. In a recent study, it is shown that 48% of patients who suffered postoperative complications had hypertension, and 30% had dyslipidemia [62]. In addition, hypertension and hyperlipidemia are shown as predictors of postoperative complications [62]. While in other studies, it is noticed that 52.9% of patients with diabetes and 57.6% of patients with OSA suffered moderate complications after surgery [63]. In turn, the preoperative weight is also a predictor of mortality and complications of surgery [61, 64], showing a greater risk of mortality with an increase in body mass index [65].

Figure 5. Percentage of subjects with specific comorbidities in patients waiting for bariatric surgery.

Along with this, it has been reported that between 52% and 91% of patients awaiting BS have non-alcoholic fatty liver disease, while between 35% and 88.6% suffer from non-alcoholic steatohepatitis [66–70]. These liver diseases, together with high levels of visceral fat can cause certain disadvantages and complicate the surgical process. On the one hand, deposits of fat tissue in the liver turn it into a more fragile organ. Which increases the risk of injury and hemorrhage due to surgical manipulation [71, 72]. On the other hand, a greater hepatic volume, especially a greater volume of the left liver lobe, difficult the approach to the gastroesophageal junction and the visualization of top portion of the stomach and the retroesophageal area [71, 73]. In fact, in gastric bypass, a larger size of the liver has been shown to be the main responsible for the conversion of laparoscopy to open surgery in 48% of cases, while steatohepatitis is a predictor of this conversion [74, 75].

In addition to comorbidities, the functional status of patients also contributes to an increased risk of morbidity/mortality, showing that subjects who are dependent or partially dependent have a greater risk of suffering complications in the surgical process [59, 76–78]. This suggests that physical fitness level at the time of the operation may be relevant, although unfortunately, there are few data on this subject in bariatric patients. In mixed intra-abdominal surgical procedures, it has been shown that an anaerobic threshold $<11 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ show a cardiovascular mortality ratio of 18%, however, when the anaerobic threshold is $\geq 11 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$, the mortality ratio decrease until 0.8% [79]. Furthermore, an anaerobic threshold $<10.1 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ predicts the number of complications [80]. In bariatric surgery, one study reported that patients with a greater number of complications, and a longer hospital stay, have a lower anaerobic threshold (with a mean of $9.9 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) [81]. While in another study, it was concluded that patients with a peak oxygen consumption of less than $15.8 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ had a greater risk of suffering post-operative complications [82].

Figure 6. Factors that influence in the complications and in mortality of bariatric surgery.

All of these comorbidities associated with morbid obesity increase the risk of suffering complications, in fact, their effects are added up, since it has been shown that the greater the number of morbidities in a patient, the greater the risk of mortality [76, 77]. Consequently, surgery is not risk-free. In a meta-analysis conducted in 2014 that included 16,156 patients undergoing BS, complications were found in 17% of the surgeries performed, being 13% for

sleeve gastrectomy, and 21% for gastric bypass [83]. This same study showed a perioperative mortality rate of 0.08% and a postoperative mortality of 0.31% [83].

To sum up, patients awaiting BS are associated with a high number of comorbidities. This, together with a very high weight, an inadequate functional status and a low physical condition, increase the risk of mortality and of suffering intra and postoperative complications. In addition, aspects such as a large liver size, a fatty liver, and a large amount of visceral fat, hinder the surgical process. Therefore, strategies must be pursued to maximize weight loss, reduce the number of comorbidities and increase the physical fitness in patients awaiting BS. The achievement of these objectives could increase the safety of patients and facilitate surgery. Both factors would allow to reduce the number of intra and postoperative complications, and reduce the time of the operation and the stay at the hospital, thus reducing the costs associated with the BS.

Usual Care before Surgery

Normally, in order to decrease these comorbidities associated with obesity and, thereby, decline the number of complications and the operative mortality rate, it is recommended to reduce the weight prior to surgery. This can have great advantages. On the one hand, it can reduce liver size between 5.3-18.7%, between 25.5-40% of the fat tissue deposited in the liver and approximately 17% of visceral fat [71, 84–86]. This can lead to a decrease in the duration of surgery [48, 73, 87], the number of intra and postoperative complications [48, 87–90] and generate a shorter hospital stay after surgery [87]. For this reason, many centers use restrictive or very restrictive diets in a period between 2-6 weeks prior to surgery. However, highly restrictive diets may cause the body shift into a catabolic state, producing that, a great part of the weight loss may be due to the loss of FFM, which can be approximately 40% of it [91]. This loss of FFM can lead to sarcopenic obesity [50], a state linked to a low functional capacity [51], a reduced RMR [92, 93] and an increase in insulin resistance [53]. Therefore, strategies should be applied that are able to provoke fat mass loss, maintenance FFM and generate a reduction in the comorbidities associated with obesity. Exercise can be an effective tool for this surgery.

It has been widely demonstrated that the addition of an exercise program to a nutritional intervention generates greater reductions in weight, fat mass and visceral fat compared to use a nutritional intervention in isolation [94–97], avoiding also FFM loss [96, 98]. Similarly, exercise by itself has shown to be effective both in achieving reductions in both visceral fat and fat deposited in the liver [97, 99, 100], aspects that, as we have seen, could facilitate the surgical process. At the same time, the implementation of an exercise program has been reported to be useful in achieving reductions in blood pressure, diabetes and waist circumference levels [101–103], as well as improvements in OSA [104, 105], which, could help to reduce the risk of suffering intra and postoperative complications. While, in turn, exercise is one of the most effective methods to obtain improvements in the functional capacity and cardiorespiratory fitness of individuals, which, as we have seen, are powerful predictors of surgical risk.

Physical Activity Levels in Patients Awaiting Bariatric Surgery

Despite the benefits that PA entails, patients awaiting BS show very low levels. Some studies have reported that 90% of patients are sedentary [106], while in others it is shown that candidates for bariatric surgery spend approximately 80% of the time in sedentary behaviors [107]. In fact, if you compare the levels of PA between subjects with a normal weight, and patients waiting for surgery, it is observed that only ~13% of the subjects in a normal weight do not perform moderate or vigorous PA, while this figure rises to ~68% in patients awaiting BS [108].

Therefore, it can be considered that very few of the patients have a healthy lifestyle. Studies have shown that only 4.5% of patients awaiting surgery meet the weekly recommendations for PA (≥ 150 min/week). Although other studies report higher percentages, only 20% of the candidates are considered active or very active [109], or perform some type of PA [110]. However, of this PA that is performed, the one that is carried out largely is walking, between 44% and 95% of the total time allocated to the activity, followed by other activities such as gardening or playing with children [109, 111]. These activities do not include resistance training, and are made at low intensities. So, we should ask ourselves if the PA that bariatric patients perform is adequate to generate fat mass losses and health benefits.

Exercise in Patients Awaiting Bariatric Surgery

Unfortunately, currently, there is a few research in which the effects of exercise have been studied in patients awaiting BS. Most studies in which an exercise program has been applied, have shown reductions in the total weight of the subjects who participated. On the one hand, a resistance training generates reductions of between 1.41-7.5% total weight, from 5.3-12.5% fat mass and between 3.86-7.8% waist circumference [112–115]. On the other hand, the realization of an exercise program that combines aerobic and resistance training, of 8 or 12 weeks duration, has shown to achieve reductions of weight, fat mass and visceral fat, with a maintenance of fat-free mass [116, 117]. In turn, a training program that included only aerobic exercise at low intensities also generated reductions in the total weight of the patients [118]. Besides, one aspect of great importance that many of the studies have in common is that there is an improvement in physical fitness, especially in the cardiorespiratory fitness [112, 114–117, 119, 120].

If the number of studies in patients awaiting BS is low, the quantity of studies examining the effects of exercise on cardiovascular risk factors (CVRF) in this population is still lower. However, in these studies there is a trend of exercise to improve CVRF. For example, a resistance training after surgery, that consisted of 3 series per exercise of 60 seconds to muscle failure, performed 3 times a week for 12 or 16 weeks, generated reductions in blood glucose of ~10% [114, 115], and showed a tendency to decrease the levels of total cholesterol (8.1%), LDL (-6.3%) and TG (-7.6%) [112].

Aerobic training has also proven to be an effective tool. In a 6-month study, patients were given a supervised training session a week in which 30 minutes of low-intensity aerobic exercise was performed and they were encouraged to do this in their homes. The results of this study showed reductions in total cholesterol, LDL cholesterol, triglycerides, blood glucose and blood pressure, resulting a great reduction of the CVR (-4.4 units) [118]. In

another study, a program of PA focused on AT, 2 days per week for 4 months, was added to the usual care, besides subjects were encouraged to increase the number of steps walked every day. This patients had reductions in CVRF, which caused a decrease in cardiovascular risk (-3.4 units), while the control group did not show any improvement. On the contrary, it had an increase in blood glucose and triglycerides [120]. In addition, shorter training programs can also generate certain benefits. By only 7 days performing a 60 minutes of aerobic training at 65% of maximum oxygen consumption has been reduced fasting insulin concentrations and the insulin area under the curve during the oral glucose tolerance test, what indicates that there has been an improvement in the action of insulin [121].

Although there are few studies in the literature, these studies show potential benefits in patients who perform exercise before surgery. On the one hand, exercise causes reductions in weight and in comorbidities associated with obesity, while it increases in cardiorespiratory fitness, which could greatly help to reduce operative complications and hospital stay after BS. On the other hand, decreases in waist circumference indicate that visceral fat is also being reduced, thus facilitating the surgical process. Therefore, the health system should seriously consider the inclusion of exercise programs prior to surgery.

3. EXERCISE IN PATIENTS UNDERGOING BARIATRIC SURGERY (SHORT-TERM)

Benefits and Disadvantages of Bariatric Surgery in the Short-Term

It has been widely argued that BS generates great benefits. In the short-term, BS causes large weight losses, causing reductions of between 20-35 kg three months after the intervention [122–124], and between approximately 35-50 kg a year after surgery, reducing to a great extent fat mass [125–127], and visceral fat [128]. Furthermore, after BS, decreases in liver volume and fatty liver levels are also generated [129, 130]. Along with this, improvements in CVRF have also been widely reported, such as decreases in resting blood pressure, glycosylated hemoglobin, LDL cholesterol, and increases in HDL cholesterol [131–133]. The results of a meta-analysis covering more than 22,000 patients showed complete remissions in 76.8% of diabetic subjects, of 61.7% of hypertensive patients, of 85.7% of patients with OSA, and a reduction of hyperlipidemia in 70% of patients [134]. All this will reduce the risk of heart disease [135, 136]. But not only physiological improvements are achieved, psychological improvements are also generated, such as increases in mental health, increased self-esteem or a decrease in depression levels [137, 138].

However, BS has, in the short-term, some disadvantages. After surgery, especially when it is malabsorptive, there is a deficiency of certain micronutrients. After gastric bypass, iron deficits have been reported in 49% of patients, of vitamin B12 in 70%, of calcium in 10%, and of Vitamin D in 50%, as well as decreases in bone mineral density [139, 140]. However, in this chapter, greater emphasis will be placed on the FFM losses. Many studies show reductions of around 10 kg of fat-free mass a year after surgery [125, 127, 141–144]. These reductions in fat-free mass can cause, among other factors, a greater insulin resistance, a decrease in the RMR and favor the accumulation of fat mass [51]. In fact, a low RMR has

been associated with weight regain in bariatric patients [145–147], which is one of the most common problems in this population, as it will be seen later [110, 148–150].

Physical Activity Levels in Patients Undergoing Bariatric Surgery in the Short-Term

As seen above, most patients awaiting BS have a sedentary behavior. However, it has been widely reported that in the short-term after BS, patients increase their PA levels [151–155]. In some studies it has been shown that the percentage of patients who did not perform any PA decreased from 37.4% to 7.6% a year after surgery [156]. Other studies have reported increases between 1225 and 2749 steps/day a year after surgery [155, 157], increasing from 30% to 46% of subjects who performed at least 150 minutes of PA per week [157]. The most frequently activity performed after surgery is walking, 54.7% of patients, while only 12.7% report performing weight lifting [157]. This, as it will be seen later, may be of great importance in weight loss and the reduction of comorbidities after surgery. However, in the same way as before surgery, subjects perform little strength training, and the intensity that can be reached walking may not report the best benefits.

Exercise in Patients Undergoing Bariatric Surgery in the Short-Term

As we have seen, after surgery, a series of disadvantages are generated, which could be minimized or even avoided by performing structured exercise appropriately. Unfortunately, there are currently few studies on this, and most of them are observational studies. These studies show greater reductions in weight in subjects who perform PA after surgery [158–160], noting that only 150 minutes per week of moderate or intense PA per week are sufficient to generate greater weight losses [161]. In addition, both higher volumes and higher PA intensities performed after bariatric surgery are associated with greater weight losses [162]. However, in the short term after surgery, the important issue is not weight loss, since both patients who perform exercise and those who do not it, have large reductions in total weight. This point should focus on the FFM, although the availability of studies on this is still scarcer, since few studies analyze the effects of exercise on body composition after surgery. They have found that a greater increase in leisure time PA, was directly associated with a smaller decrease in fat-free mass [153]. While another reported that only the completion of 30 minutes 3 or more times per week showed to be effective to increase the FFM [163]. Here the volume also seems to be important, since it has been shown that the subjects who increased their steps/day more after surgery obtained skeletal muscle maintenance [164].

However, nowadays, some research has emerged on this subject. These studies show that patients who participate in a post-surgery exercise program avoid or reduce the FFM loss [165–168], although occasionally, the difference between experimental group and control group is not significant [169, 170]. In most of these studies there is only one intervention group in which an exercise program is applied, therefore, it is not established what type of exercise can be more effective after surgery. Nevertheless, one study compared a control group and two experimental groups, one of them performed only aerobic training, and the other combined aerobic and resistance training. The results showed that the group that

included resistance training was the one that lost the least FFM, meanwhile the control group had the greatest reduction [168]. Therefore, although volumes and intensities are still to be determined, it seems that resistance training can be a determining factor in the maintenance of the FFM.

Avoiding the loss of FFM can be of great importance, both in the short and long term. On the one hand, as we have seen previously, the FFM (specifically the skeletal muscle) plays a fundamental role in the organism, so its maintenance could generate additional benefits to the surgery in the cardiometabolic profile of the patients, as well as a greater functional capacity. On the other hand, maintaining the FFM could prevent or minimize the reduction of RMR that is generated after surgery [171], and it has been associated with certain long-term problems, such as weight recovery [172, 173].

Although, after surgery there is an improvement in functional capacity (evaluated by the 6-minute walk test) [174], this is not the case when aerobic capacity is measured by oxygen consumption. It can be observed that in the studies that analyze oxygen consumption after surgery, there are increases when the results are normalized to the total weight of patients. Probably, these increases are due to the great weight loss that occurs, and not to an improvement in cardiorespiratory fitness, since absolute oxygen consumption does not increase [175, 176]. However, in studies in which an exercise program is applied, it can be seen how patients who perform it have greater rises in normalized oxygen consumption to weight, and increases in consumption of oxygen in absolute values [177–179]. The improvement of cardiorespiratory capacity can be of great importance in CVRF, since it is associated with a lower cardiometabolic risk [180, 181].

As previously shown, BS, by itself, generates large improvements in cardiometabolic risk factors. However, there is a proportion of patients to whom the BS fails for reducing certain comorbidities. Some authors have called these patients as resistant to bariatric surgery [182]. These patients, besides not showing improvements in cardiometabolic parameters, have lower weight losses after surgery. Although the reasons for this variability between patients are not clear yet, there are different common aspects in the “non-responsiveness to surgery,” such as gender, age or preoperative weight, emphasizing an inadequate PA, since it is a factor that can be modified.

However, although the role of the exercise on CVRF remains to be determined, due to the lack of studies, it seems that it can have a positive effect. In an observational study it was obtained that, one year after surgery, total and LDL cholesterol were higher in the sedentary subjects ($<1,250$ Mets/14 days), while the HDL cholesterol, although the difference was not significant, showed a tendency to be higher in active subjects ($75.5 \text{ mg}\cdot\text{dl}^{-1}$ vs $68.6 \text{ mg}\cdot\text{dl}^{-1}$) [106]. Another study showed that, also one year after surgery, patients who reported an average of 96.8 minutes of aerobic exercise per week had a higher resolution of diabetes and OSA than patients who had an average of 21.1 minutes per week [183]. In addition, positive associations have been found between the number of daily steps and insulin sensitivity, and between the increase in daily minutes of PA and HDL cholesterol 9 months after surgery [184].

Recently, some experimental studies have emerged on this subject. In these studies, in the short-term (6-9 months), there are no differences between patients participating in an exercise program, and those who do not, showing all patients similar improvements in lipid profile and blood pressure levels at rest [178, 179]. However, after surgery, exercise seems to be effective in glucose metabolism. In one study, a 12-week exercise program was performed, in which

2000 kcal a week was tried to consume by aerobic exercise at 60-70% of VO_{2max} [178]. The results of this study showed a reduction in the incremental area under the curve postprandial blood glucose response in the experimental group. In turn, other studies have shown greater improvements in insulin sensitivity by performing only ~120 minutes of aerobic exercise per week, at an intensity of 60-70% [179, 185].

Although the limited availability of studies in this regard does not allow to reach a clear conclusion, it seems that the performance of aerobic exercise in the short term after surgery (6-9 months) produces additional benefits in the improvement of glycemic control. While, between 9-12 months after BS, it is observed that PA can contribute to increase HDL cholesterol, and a higher resolution of various comorbidities, such as diabetes. This seems to indicate that the use of exercise programs can help improve the cardiovascular profile in patients who do not respond adequately to surgery.

4. EXERCISE IN PATIENTS UNDERGOING BARIATRIC SURGERY (MEDIUM AND LONG-TERM)

Benefits and Disadvantages of Bariatric Surgery in the Medium and Long-Term

Bariatric surgery generates diverse benefits, which decrease the risk of suffering a cardiovascular disease [135, 136], and in the long term it contributes to the fact that subjects with morbid obesity undergoing BS show an increase of approximately 7 years in their life expectancy [186].

However, one of the biggest disadvantages after BS is weight regain, which is shown above in all studies that have a follow-up period ≥ 5 years [187]. Weight regain occurs in a large proportion of patients (19.2% -58.5%) [110, 148–150], and it is positively associated with the postoperative period, [110, 188] that is, the longer after surgery, greater weight regain. Therefore, it can be seen how patients decrease from 70% of EWL in the second year of surgery to 42% at 10 years. While other studies have shown that 6 years after surgery, 64% of patients had a% EWL below 50% [189].

Bariatric surgery		
	Benefits	Disadvantages
Short-term	➤ Fat mass loss ➤ Improve comorbidities ➤ Improve functional capacity ➤ Quality of life increase	➤ Fat free mass loss ➤ Deficiency of micronutrients ➤ Bone mineral density decrease ➤ Resting metabolic rate decrease
Medium and long-term	➤ Cardiovascular disease risk decrease ➤ Life expectancy increase	➤ Weight regain ➤ Relapse in comorbidities ➤ Revisional surgery ➤ Quality of life decrease

Figure 7. Benefits and disadvantages of bariatric surgery.

On the one hand, weight regain can lead to revisional surgery, which has been seen between 15.4% and 36% of patients [148, 150, 190]. On the other hand, weight regain can be accompanied by relapses in different comorbidities [191]. One study showed that the incidence in diabetes, hypertension and hypertriglyceridemia increased from 1% to 7%, from 24% to 41% and from 8% to 17% respectively between the 2nd and the 10th year of the surgery [192]. Similar results have been shown in the short-term, observing how the complete remission of diabetes decreased from 50.7% patients a year after surgery to 20% at 5 years, while the complete remission of the cholesterolemia decreased from 40% to 26.1% [193]. Furthermore, type 2 diabetes mellitus relapse ranges have been obtained from 19% to 35.1% of patients [194–196], and these relapses have been associated with weight regain [195, 197]. While, regarding hypertension, Benaiges et al. showed a range of relapse in 21.9% of patients between the 1st and 3rd year of surgery, with these patients showing a lower% EWL than subjects who did not relapse [198].

Physical Activity Levels in the Medium and Long-Term after Bariatric Surgery

Although there are few studies that analyze changes in PA levels in the medium and long term, it seems that over time they tend to decrease. Sjöström et al. found as the proportion of subjects who were active in leisure time and work increased after surgery, reaching a peak around the year of the same, and that from this moment began to reduce, until at 10 years, there was a great reduction in this proportion [192]. In turn, another study showed an increase in steps/day (+1526.8) and in the percentage of patients who performed 150 minutes of moderate or intense activity per week (+10.2%) two years after surgery. However, between the 2nd and the 3rd year of surgery both variables were significantly reduced (-278.9 steps/day; -7.1%, respectively) [199]. In a long-term study it was reported that at ~9 years of surgery, although 71.8% of patients reported being more active than before CB, but only 11.7% of patients performed $\geq 10,000$ steps/day (daily recommendation), while 36.6% performed less than 5000 steps/day. In addition, 7 years after surgery, only 48% of patients reported performing ≥ 1 exercise session per week, while the average time spent sitting turned out to be 7.3 hours per day (200). So, it can be concluded that in the medium and long term there is a decrease in the levels of PA, there being a large proportion of patients who are not very active, and spend much of their time in sedentary behavior.

Exercise in Patients Undergoing Bariatric Surgery in the Medium and Long-Term

From our knowledge, there are few studies that investigate the role of exercise on CVRF in the medium and long term after BS. However, as we have seen above, weight control can be of great importance for CVRF, and exercise can be a fundamental tool for this. In one study, PA was evaluated 36 months after surgery, and it was found that subjects who performed between 0 and 59 minutes of aerobic exercise had an EWL of 33%, while those who performed ≥ 150 minutes had an EWL of 54.1%, which is considered a successful weight

loss [183]. Herman et al. showed that patients who reported ≥ 1 weekly sessions of at least 30 minutes of moderate or vigorous exercise were more likely to maintain at least 50% of their initial weight loss (OR: 2.6), and had a lower probability of weight regain than less active subjects (OR: -3'1) [201]. In another study that modified the behavior of the patients, modifying eating habits and increasing levels of PA, it was obtained that the subjects of the experimental group had a greater weight loss at 12 months after surgery, and subsequently, they got a maintenance of the lost weight. However, subjects who did not change their habits showed a decrease in their %EWL between 12 and 36 months after surgery (from 57.5% to 49.1%) [202].

Although the majority of studies regarding this topic are observational, some experimental study has also been carried out. In one study, patients who had <50% EWL after 3 years or more of surgery were recruited. The experimental group underwent a 6-month behavioral intervention that consisted in reducing caloric intake, and in the prescription, a PA program. The results of this study showed a significant decrease in %EWL after the intervention only in the experimental group (-6.6% EWL) [203]. Last, in one study an exercise program that combined aerobic and resistance training at moderate intensities was applied in patients who had a BMI ≥ 30 between 12-24 months after surgery. The group that performed the exercise program had reductions in weight and resting blood pressure, while in the control group there was a tendency to increase weight [204].

In the studies it is observed that adding exercise to BS generates greater weight loss and that it is an effective tool to achieve weight maintenance that has been lost through surgery. In addition, exercise can be an efficient method to generate weight loss in patients with an inadequate weight loss or who suffer from weight regain.

5. ORIENTED NEW TRENDS TRAINING TO HEALTH

Traditionally, to achieve weight loss in obese people, it has been recommended to perform aerobic exercise at moderate intensities, without giving much importance to the resistance, defending the volume of aerobic activity as a determining factor. While some authors stated that for achieving weight loss should be performed 5 days a week of aerobic activity, with a minimum duration of 60 minutes per session [205]. Other organizations, such as the ACSM in its position stand in 2009, proposed that performing 150-250 minutes per week of PA at moderate intensity will result in modest weight reductions, but that greater than 250 minutes per week is when the greatest benefits are achieved [206]. However, the role of resistance training on weight loss has not been given more relevance [206, 207].

Currently, this trend is changing, and it seems that there are other methods that can be more effective than aerobic training. Resistance training increases fat-free mass, and with it the RMR (208), so it can be very important both to generate weight loss and to avoid weight gain. In addition, it has been shown to be as effective in reducing CVRF as aerobic training [209]. Therefore, if resistance training is added to aerobic training, it can be an effective strategy for weight and cardiometabolic control. In recent years, research has emerged that confirms this theory. It has been found that, by combining resistance and aerobic training in the same training program, greater reductions in weight, fat mass, waist circumference and abdominal fat are achieved than through aerobic training in isolation [210–214]. Generating

at the same time increases in fat-free mass [212–214]. Even the benefits of CVRF are also greater when both types of training are combined [102, 215].

Figure 8. Impact of different exercise modalities on body tissues and cardiovascular risk factors. Dates obtained from Davidson et al. [230] and Snowling et al. [231].

On the other hand, training intensity is showing itself as a decisive component. Currently, numerous research are reporting the benefits of high intensity interval training (HIIT). HIIT is a type of exercise that combines short periods at high intensities and low intensities in the same training session, thus, when applying recovery periods, training time in more intense areas is prolonged in relation to continuous training [216]. The greater the intensity of aerobic training, the greater will be the increase in excess post-exercise oxygen consumption (EPOC) [217]. The increase in EPOC, in turn, has been related to a greater mobilization of fatty acids [218], in both healthy and obese subjects [219, 220]. This means that HIIT is an effective method to achieve fat loss as continuous training at moderate intensities [221]. Other benefits are also attributed to it, as it decreases insulin sensitivity [220, 222], reduces cholesterol [222–224], glycemia [225] and blood pressure levels [224, 226], in addition to achieving greater increases in cardiorespiratory capacity than through continuous training at moderate intensities [227]. All this results in that this type of training helps reduce the risk of suffering cardiometabolic pathologies [228].

However, one of the main advantages of HIIT is that all these results are achieved in 40% less training time than if continuous training were employed [221], which leaves more time in a training session so that other capacities can be worked on, as the strength. As we have seen previously, resistance training can provoke great benefits, but training intensity is also important. In studies with obese subjects who train at intensities between 70–80% of the repetition maximum (RM), gains of fat-free mass are obtained [212–214]. A recent review that analyzes the effects of training intensity, has concluded that the intensities that cause more favorable changes in body composition and in certain CVRF are between 75–80% of the RM for resistance training, and above 75% $\text{VO}_{2\text{max}}$ for aerobic training, and not between 55–75%, as has been traditionally prescribed [96].

Therefore, adding an exercise program to a nutritional intervention can be an effective strategy to maximize the results in weight loss and in the improvement of CVRF. The inclusion of strength training in an exercise program can avoid reductions in FFM, while aerobic training at high intensities can, among other benefits, generate greater losses of fat

mass. Consequently, for an exercise program to be as efficient as possible and generate the greatest benefits in the CVRF, it should combine both types of exercise (resistance and aerobic training), initiated at moderate intensities, but progressing to train at high intensities.

CONCLUSION

Exercise may be of great importance in the control of CVRF in bariatric patients. This control of the CVRF can be done in different ways. On the one hand, exercise by itself generates improvements in glycemic control, hypertension, lipid profile and other comorbidities associated with obesity. On the other hand, when a nutritional intervention is combined with exercise, large weight losses occur, which is associated with an improvement in comorbidities.

Furthermore, it is important to notice that cardiorespiratory fitness is a very high importance for cardiovascular risk factors, and the fact of rising it is able to prevent to some degree, cardiovascular diseases. In the same way, skeletal muscle is a powerful endocrine organ that must not be forgotten. It has relevant functions such as elimination of post-prandial glucose, glucose storing or a high oxidation of fatty acids at rest. For that reason, in these patients who have a high cardiovascular risk, exercise must be aimed at the rising of cardiorespiratory fitness, maintaining skeletal muscle levels and rising muscular quality.

However, due to different disadvantages that BS can present, the objectives of the exercise should be different at each stage of the surgery. Prior to surgery, it should be sought to generate greater losses of fat mass, especially of visceral fat, and to help reduce the comorbidities associated with obesity, in addition to increasing cardiorespiratory fitness. All this will reduce the surgical risk, and can help to decrease the number of complications and mortality in these patients, as well as a shorter hospital stay, which could reduce the health cost of the operation.

Figure 9. Exercise goals before and after bariatric surgery.

Bariatric surgery generates large losses of fat mass by itself, therefore, after surgery (especially in the first months), exercise should be oriented mainly to the maintenance of FFM, of the RMR and of the bone mineral density, for that reasons, the resistance training is

fundamental. In addition, exercise can help by reducing comorbidities in patients who fail through bariatric surgery.

Normally, after BS there is a point of maximum weight loss, which is usually reached between 12-24 months after surgery. At this point, exercise should focus on maintaining the weight loss through BS. Possibly, this would be an effective strategy to avoid relapse in comorbidities that occurs in some patients, since these relapses are associated with weight regain.

ABSTRACT

The pathogenesis and progression of acute cerebral ischemia (CI) is a complex process involving oxidative stress. During CI, loss of oxygen occurs and the brain becomes unable to adapt to the resultant anaerobic metabolism. Also, levels of ATP (adenosine triphosphate) in the brain fall within few minutes and removal of metabolic products slows down. Reactive oxygen species (ROS) are involved in the irreversible disruption of the function of cellular macromolecules and the initiation of cellular signaling pathways after CI. There are two types of CI: focal ischemia (localized to specific regions of the brain) and global ischemia involving a larger area of the brain. In patients with carotid atherosclerotic disease, carotid endarterectomy (CEA) is the surgical procedure used to reduce the risk of stroke. During and after a CEA, cerebral monitoring is important in order to ensure appropriate and prompt management of perioperative complications such as stroke, embolization, dissection of the arterial wall and acute arterial occlusion. During cross-clamping of the internal carotid artery (ICA), prompt

detection of cerebral hypoperfusion can guide surgeons to modify their surgery technique accordingly. Near-infrared spectroscopy (NIRS), a non-invasive monitoring method, allows continuous real-time monitoring of cerebral hemoglobin oxygen saturation (ScO₂) in a small area of the frontal cortex. This monitoring tool is based on the principle that some biological materials, including the skull, are relatively permeable to near-infrared light. This spectroscopic method is applied in many medical diagnostic fields.

Keywords: carotid endarterectomy, cerebral ischemia, neuromonitoring, near-infrared spectroscopy

1. CEREBRAL ISCHEMIA (CI)

Brain function relies on aerobic metabolism in order to meet its substantial energy needs and cerebral tissue is highly sensitive to brief periods of ischemia [1, 2]. Focal ischemia as a result of occlusion of an artery in the brain is the most common type of stroke [3]. A major artery obstruction usually causes tissue infarction with non-selective loss of cells including astrocytes, neurons, and oligodendrocytes in the affected parts of the brain, due to the disrupted mitochondrial function and release of apoptogenic proteins [4]. Different parts of the brain have different sensitivity thresholds for ischemic cell damage [1, 2]. Also, particular populations of neurons such as pyramidal CA1 neurons (CA refers to *cornu Ammon*, Latin for Ammons horn) are more sensitive to ischemia, as well as the hippocampus, while more resistant neurons are dentate granule neurons [1, 2]. The brain is in general very sensitive to oxygen deprivation; the parts such as the amygdala, prefrontal cortex, and hippocampus are structurally and biochemically sensitive to stress, however, these changes are mainly reversible [5].

Cerebral damage secondary to brain ischemia is multifactorial. The physiological, biochemical, genetic and molecular changes disturb brain normal activities through a degradation of cellular integrity mediated by calcium overload, apoptosis, ionic imbalance, oxidative stress and excitotoxicity mediated by glutamate [6-8]. These processes affect cell organelle function such as membranes, nuclei, lysosomes, endoplasmic reticulum, and mitochondria and leads to damage of vascular elements, glia cells and neurons [6]. Mitochondrial function in focal ischemia is disturbed by the impaired inflow of oxygen and glucose to the tissues and additionally modified by ischemia-induced changes in mitochondrial features [6, 9]. The limited ability of cells to synthesize adenosine triphosphate (ATP) leads to a deterioration of cellular responses to the activity of other damaging factors and can affect cell death pathways. In cases of CI, death and dysfunction of cerebral neurons and neurological defect can be repressed by size and location of the affected cerebral region [6, 8].

There is a critical level of brain tissue oxygen tension and blood flow [6]. The decrease in blood flow, either permanent or temporary, to a certain part of the brain induces ischemic brain changes [6]. It is well-known that time-dependent neuronal events are initiated by cerebral blood flow reduction [6, 10, 11]. Blood flow in the brain tissue is normally about 45 to 60 ml blood/100g/min [6]. The need for oxygen in the brain of an adult human compromise about 20% of the total oxygen requirement, whereas its relative size, is 2% of the total body size [12]. Glucose and ATP concentrations during the first 5 min of arterial occlusion fall

markedly [13]. Also, there is an imbalance in the levels of adenosine monophosphate (AMP), adenosine diphosphate (ADP) and ATP [4]. Cerebral phosphocreatine presents, for a brief time period, a source of energy that provides ATP production from ADP in a creatine kinase catalyzed reaction. In normal brain functioning creatine is synthesized in the brain and is used to form phosphocreatine in a reaction catalyzed by creatine kinase [14]. It has been documented that pretreatment with creatine improves severe anoxic or ischemic damage that is caused by anoxic depolarization which is a consequence of decreased of ATP and is mainly electrophysiological event [14]. Phosphocreatine may have a neuroprotective effect on focal cerebral ischemia-reperfusion (IR) injury which may be connected with apoptosis while phosphocreatine pretreatment alleviates neurobehavioral score and brain swelling [15].

After middle cerebral artery occlusion, a rapid deterioration of cellular energy state was observed (ATP content was lowered to 20-40% of control value) [13]. There are available data [16] which demonstrate that certain compounds, such as N-tert-Butyl- α -phenylnitron, markedly improve recovery of the cerebral energy status after transient and focal ischemia. Reduced levels of cellular ATP during CI consequently cause the failure to maintain ionic gradients and the depolarization of neurons and other brain cells [6, 17]. Disturbed availability of ADP and AMP levels have the consequence of changing lactate concentrations and this is associated with rising extra- and intracellular pH values [13]. Energy in the brain is generated from glycolysis and oxidative phosphorylation [6]. Reduction of oxygen and glucose supply (by lowering ATP levels) leads to membrane depolarization and changes in the concentration gradients of Na^+ and K^+ across the plasma membrane resulting in activation of voltage-gated calcium channels [6]. This results in an excessive release of excitatory amino acids (in particular glutamate) to the extracellular space [6, 18].

Cerebral ischemia as a stress factor activates the hypothalamic-pituitary-adrenal (HPA) axis [19-21]. According to several reports, HPA axis activation is one of the first prominent responses to ischemic insult [19-21]. It was shown that increases in the HPA axis activity may cause a prolonged and considerable increase in the concentration of extracellular glutamate that is followed by the death of central neurons [6, 22-24]. Transient acute CI during the period of carotid artery cross-clamping, as part of carotid endarterectomy (CEA), may lead to an activation of the HPA axis with endocrine function abnormalities and hypermetabolic stress reaction [25, 26]. This reaction induces hemodynamic, inflammatory, metabolic and immunologic changes in order to maintain homeostasis and facilitate recovery [25].

Impaired neuronal function by an excessive release of glutamate at synapses activated by glutamate receptors represents a pathophysiological mechanism called excitotoxicity [22]. Excitotoxicity is described as cell death caused by excitatory amino acids [6], and these processes are essential for the development of CI [27, 28]. Excitotoxicity contributes to the synthesis of free radicals due to impaired mitochondrial function [6]. There is a high concentration of glutamate in the central nervous system (CNS), particularly in presynaptic regions of different hypothalamic nuclei [27]. Under physiological conditions, glutamate plays an important part in the modulation of neuroendocrine secretion [27, 29], while under pathophysiological conditions, such as CI, the role of glutamate in modulating stress reactions and hormone release has not been well-explained yet [27]. Poor functional outcomes have been reported following elevated catecholamine levels that, in turn, aggravate CI [21, 30].

Ischemic brain injury is characterized by several mechanisms that cause ionic imbalance, excitotoxicity, apoptosis and oxidative/nitrosative stresses resulting in cell death [31]. These

processes lead to disruption of membrane integrity, loss of cellular homeostasis and cell death by necrosis or apoptosis [31]. Numerous studies suggest that oxidative stress is a major occurrence that leads to cerebral damage induced by CI [6, 32-34]. During treatment of CI, there is a need to consider the relationship between metabolic rate, oxygen free radicals produced by metabolism and oxygen concentration [35].

2. CEA AND CI

The ideal sites for atherosclerosis generation are those of supra-aortic arteries, particularly regions at the carotid bifurcation, which may cause significant stenosis and may be the cause of acute CI, responsible for about 20% of all strokes [36-39]. There are different patterns of the progression of atherosclerotic disease i.e., it could be slow or remain stable for a long time [36]. The main aim of performing CEA is to prevent the development of potentially fatal embolic and thrombotic stroke. CEA is a well-established surgical procedure for carotid artery stenosis, during which plaques that are clogging the artery are removed [36]. CEA is an established procedure in individuals with high-grade stenosis of the carotid arteries but complications and adverse outcomes are possible and must be maintained at low levels. The main complications are major stroke and death [40, 41].

Carotid artery stenosis may cause a cerebral embolism, one of the 3 main causes of stroke. The obstructive material is most often a blood clot but it may be a fat globule, air bubble, tissue, or clump of bacteria. The efficacy of CEA has been proved to prevent stroke in patients with atherosclerotic carotid bifurcation stenosis [36, 38, 42]. The benefits of CEA in females without symptoms are significantly less than for men [36]. During the procedure of CEA, the surgeon opens the artery and removes the area of plaque. There is a newer minimally invasive procedure, endovascular stenting, that uses a balloon to expand the blood vessel followed by inserting a stent to maintain the patency of the site [43].

The benefits of CEA depend on the incidence of adverse neurological events during the intraoperative and postoperative period. Approximately 80% of strokes are due to ischemic changes [44]. One of the important surgical complications during CEA is hemorrhage or hyperperfusion syndrome due to the sudden increase in perfusion of vasculature distal to the site of the stenosis [45]. Also, during or after CEA, stroke may occur due to cerebral blood flow reduction and cerebral hypoperfusion throughout the period of cross-clamping of the internal carotid artery. Otherwise, the most common causes of the post-operative cerebral events include cerebral hyperperfusion syndrome (CHS) and thromboembolism. The development of thrombotic obstruction could be explained with increased and repeated accumulation of clotting factors, primarily fibrinogen, calcium and fatty deposits [46]. Observed lower levels of cerebral blood flow (range: 20-40% of reference values) may be tolerated for several hours with complete recovery of all functions after reperfusion [47]. Comorbidities such as heart failure and diabetes significantly increase the risk of unwanted complications during or after CEA [48].

Importantly, the degree of metabolic and endocrine reactions in response to the stress of surgery, have been reported to be proportional to the poor postoperative outcome because of potential adverse systemic effects, such as impaired oxygen supply-demand ratio, immune dysfunction and increased catabolism. Serum cortisol levels are proportional to the degree of

stress, and represent an endocrine and sympathetic nervous system response to stress [49 75]. This condition may be directly associated with possible CI during cross-clamping of the internal carotid artery [25].

3. NEAR-INFRARED SPECTROSCOPY (NIRS) IN CI AND CEA

3.1. NIRS in General

NIRS, first proposed by Jobsis in 1977, is a technique that enables the measurement of oxygen and deoxyhemoglobin concentration in the brain using light from the near-infrared spectrum which can penetrate the skull [50]. The first NIRS study in humans was published in 1985 by Ferrari and colleagues [51]. After the United States Food and Drug Administration (FDA) approval in 1993, the first commercially available NIRS device, INVOS 3100 was marketed [52]. Near-infrared light was then used to measure regional cerebral tissue oxygenation [52].

The application of NIRS is based on the fact that near-infrared light when passing through the skin and skull, may be absorbed by certain biological molecules in the brain [53]. These methods include a monitor and self-adhesive pads that consist of the detector and NIRS-emitting light source sensor. These self-adhesive pads are usually applied to the skin of the forehead for noninvasive measuring cerebral oxygenation. The emitted light may be absorbed, scattered, reflected or redirected. Proteins such as hemoglobin, cytochrome, and bilirubin are the primary light-absorbing molecules in tissue. The light spectrum changes in contact with hemoglobin molecules and these changes are directly proportionate to the level of hemoglobin oxygenation. According to the Lambert-Beer law, measurement of tissue hemoglobin oxygen saturation is determined by the difference in intensity between a transmitted and received light delivered at specific wavelengths [52]. The intensity of transmitted light depends on the concentration of the substance through which the light passes as well as the distance between the light source and the absorbing substance. The amount of light detected by the photodetector decreases with increasing the concentration of chromophores, and with the increasing distance light travels through a substance. According to the Lambert-Beer law, the distance that a light passes between the transmitting source and detector, the concentration of chromophore as well as the absorption coefficient of the chromophore are the main determinants of the absorption level of the emitted light [52].

Cerebral NIRS devices are designed to measure average tissue oxygen saturation and to provide information about hemoglobin saturation in venous, capillary and arterial blood. For the cerebral cortex, average tissue hemoglobin is distributed in a proportion of 70% venous and 30% arterial, based on correlations between positron emission tomography and NIRS [54]. NIRS-based cerebral oximetry measures the percentage of the oxygenated chromophore hemoglobin to total hemoglobin (including oxygenated and deoxygenated hemoglobin), expressed as cerebral tissue oxygen saturation (ScO_2), in the area about 2 cm below the scalp. This method basically uses the fact that oxygenated (HbO_2) and deoxygenated hemoglobin absorption properties are different: oxygenated hemoglobin absorbs less red light at wavelength 600-750 nm and more infrared light at wavelength 850-1000 nm, compared with deoxygenated hemoglobin that absorbs light at wavelength 740 nm [55]. Usually, two

detectors and emitter are used: the proximal detector detects photons reflected from superficial tissues (bone and extra-cerebral tissue) and the distal one detects those from deeper tissues. The space between the sensor and light source is one of the determinants of the spatial resolution of the emitted light. After “banana-shaped” course of the light, from the emitter to the detector, the monitor using the appropriate algorithms, differentiates the two forms of oxygenated and deoxygenated hemoglobin in order to determine the regional cerebral tissue oxygen saturation (ScO_2) in the frontal lobes [56].

There are several approved NIRS devices including the following: (INVOSTM, Somanetics/Covidien, Inc, Boulder, CO; EQUANOXTM, Nonin Medical Inc, Plymouth, MN; FORE-SIGHTTM, CAS Medical Systems, Branford, CN; NIRO, Hamamatsu Photonics, Hamamatsu City, Japan; CerOxTM, Ornim Medical, Lod, Isreal; the TOS-96, Tostec, Tokyo, Japan) [57]. NIRS is easily applicable in all patients at low cost because it provides information about cerebral oxygenation without the need for specialized personnel. NIRS has also been applied in cardiac surgery where it provides valuable information that might lead to reduced neurologic complications and improved patient outcomes [58]. Nevertheless, the clinical application of NIRS has concerns like oversampling volume and sources of extracranial contamination. Commercially available equipment employs principles of optical attenuation from several wavelengths of light by 3 different spectroscopy principles: time-resolved, phase-resolved and spatially resolved spectroscopy. Quantification is enabled by various algorithms [59]. NIRS may be used at different sites for measuring oxygen saturation. Non-invasive cerebral oximetry uses NIRS for the measurement of regional oxygen saturation in the frontal lobe, which includes an area of the brain which is most prone to hypoxemia as a watershed area between the anterior and middle cerebral artery territories. ScO_2 is primarily an indicator of the equilibrium between cerebral oxygen supply and demand. The obtained value provides information about cerebral tissue saturation. Although, venous blood may represent on average 70-75% of the volume of the total blood in the measured brain tissue in the frontal lobe, there is inter-individual variability in measured regional ScO_2 [60].

3.2. NIRS in CEA

It is crucial to evaluate cerebral blood flow during CEA, but it remains challenging to correctly evaluate cerebral blood flow in the operating room. Recently, a high accuracy NIRS has enabled precise cerebral blood flow estimation following injection of indocyanine green (ICG) [61]. NIRS together with indocyanine green kinetics measurement (NIRS-ICG) can predict the development of postoperative hyperperfusion (CHP) in patients who underwent CEA and carotid artery stenting [62]. Most patients undergoing CEA have sufficient intra-cerebral collateral blood flow to tolerate clamping of one of the carotid arteries. In subjects with poor circulation, the risk of CI can be reduced by shunt placement. However, placement of the shunt is sometimes technically difficult and may carry a risk of arterial dissection, shunt thrombosis or air embolism [63, 64]. Shunt placement is more complicated in patients under general anesthesia (GA) where there is no possibility of monitoring neurological function. In that case, surrogate markers are normally used [65]. Stump pressure (SP) is a widely used method but the cutoff pressure when shunting is necessary is still matter of debate and various thresholds have been proposed [66].

NIRS has sufficient sensitivity and specificity in predicting CI and the need for hemodynamic optimization and shunt placement making it an alternative to SP measurement [65]. Blood pressure augmentation and perfusion improving via collateral circulation have inter-individual variability and is difficult to determine in advance of surgery.

There are numerous devices applicable for cerebral function monitoring, aiming for timely detection of CI during and after surgery [67]. The monitoring tool should provide information about adequate brain perfusion, oxygenation, and neurophysiological function, especially during carotid clamping and shunting. Intraoperative monitoring is useful as guiding technique (for selective usage of shunting) and anesthesia (correction of arterial blood pressure, partial pressure of carbon dioxide in arterial blood (PaCO_2), systemic arterial oxygen saturation, cardiac output (CO), hemoglobin concentration), while monitoring during postoperative period provides fast reaction, if the signs of either increased or decreased, cerebral blood flow are present [68]. In one study included 60 patients undergoing CEA [59], there was a significant correlation between changes in regional cerebral oxygenation and changes in Transcranial Doppler (TCD) measured cerebral blood flow velocity ($r = 0.56$, $p < 0.0001$) during internal carotid artery clamping. This study supports the reliability of NIRS in detecting changes in cerebral oxygenation. There was no correlation between skin laser Doppler flow velocity and cerebral tissue oxygenation during external carotid artery clamping. The sensitivity of NIRS measured cerebral tissue oxygenation for detecting intracranial and extracranial flow changes was 87.5% and 0%, respectively. The specificity of these measurements were 100% and 0%, respectively [59]. Another study involved 596 patients who underwent CEA under GA reported that an 11.7% (cutoff point of 12% decrease in ScO_2) decrease from baseline in ScO_2 had a sensitivity of 75% and a specificity of 77% with a positive predictive value of 37% and a negative value of 98% for detecting neurological complications [69].

NIRS still has some limitations such as a lack of published data if it can detect embolic insult [69] which represents a significant factor in determining patient outcome. Advantages of using NIRS during CEA is real-time measurement, noninvasiveness and simplicity of use. We conclude that NIRS is a reasonable choice for monitoring cerebral hypoperfusion during and after CEA.

3.3. Other Methods for Monitoring Cerebral Function during and after CEA

During CEA surgery, carotid artery cross-clamping and temporary cessation of cerebral blood flow are tolerated, but in some patients with decreased collateral perfusion through insufficient blood flow via the circle of Willis, CI may still develop. Shunt insertion may prevent cerebral hypoperfusion during carotid clamping. For patients undergoing CEA surgery under GA, there is no clear recommendation for using a shunt during carotid artery cross-clamping. Based on results of cerebral perfusion, surgeons are able to give the proper recommendation about the application of shunt [70-73]. Shunting represents a risk for possible adverse effects such as intimal damage or dissection, distal embolization and acute occlusion. So, selective shunting may be a better choice over routine shunting [74]. During CEA cross-clamping, monitoring of cerebral perfusion and function may be performed by the using various methods, including electroencephalography (EEG), transcranial Doppler (TCD), measurement of the stump pressure (SP, the blood pressure measured in the internal

carotid artery distal to the cross clamp), somatosensory evoked potentials (SSEPs), regional cerebral oxygen saturation monitoring (NIRS - ScO₂) or direct neurological monitoring of the awake patient during carotid cross-clamping.

The measurement of evoked potentials and electroencephalography (EEG) are a useful technique for neurophysiological function monitoring; SP measurements and TCD provide information about hemodynamic status, and NIRS provides data on cerebral oxygenation status and balance between regional O₂ supply and demand [58]. Each monitoring technique has its strengths and weaknesses. The main advantage of performing surgery under local anesthesia is that the patient is awake during carotid artery cross-clamping, providing direct neurological monitoring with less shunt use which is accepted as “gold standard” [57]. This type of neurological monitoring has certain disadvantages in cases of a patient that is non-cooperative, claustrophobic, with neurologic diseases, or unable to remain still and follow instructions. A meta-analysis reported that the best neurological monitoring and brain function assessment was found by the combined use of SP and either EEG or TCD [75]. Although these methods are associated with the highest sensitivity and specificity for cerebral ischemia detection, there are difficulties with their application in clinical practice because they require special skills. TCD measures local blood flow velocity in a cerebral artery and is useful for correct diagnosis of hypoperfusion, thrombosis, hyperperfusion or embolic load. The interpretation of TCD results depends on who performs the test. TCD cannot be used in about 15-20% patients due to the lack of a transtemporal window attributed to temporal hyperostosis [76]. Also, there is a high risk of dislocation of the TCD probe due to proximity of the surgical field. GA and surgical diathermy may change SSEPs and EEG signals and may cause wrong diagnosis [52]; this is a disadvantage of these 2 techniques. For EEGs an experienced team is required for correct readings. Another disadvantage is that this method of monitoring is time-consuming. Measurement of SP after carotid artery clamping is also a useful method for cerebral blood flow assessment, but it is not widely accepted because it presents a discontinuous monitoring variable that cannot detect ischemia developing later during the performance of the arterectomy [52] and the results are affected by arterial pressure, partial pressure of carbon dioxide, type of anesthetic agent and the other factors [52].

Moritz and colleagues [77] conducted a prospective study (48 patients were included) with a goal of comparing the accuracy and efficiency of different neurological monitoring techniques in detecting cerebral ischemia during CEA. They compared the results of TCD, SEP, NIRS, EEG monitoring and SP, with awake clinical monitoring as the gold standard of monitoring of the level of cerebral perfusion during arterial clamping. NIRS, TCD and stump pressure exhibited similar accuracy, while SSEPs monitoring is least accurate in the detection of the onset of ischemia. The main disadvantage of this analysis is that monitoring of the level of cerebral perfusion and function during arterial clamping during CEA is particularly useful in patients operated under GA while in the Moritz et al. study surgery was performed under LA [77].

A recently published systematic review included 6 randomized controlled studies, involving 1270 patients, that compared routine shunting with selective shunting and no shunting in patients undergoing CEA [78].

CONCLUSION

Cerebral monitoring during CEA provides useful information regarding changes in cerebral blood flow and cerebral function, which might otherwise be missed. NIRS is a non-invasive monitoring method that may provide useful information on the most appropriate management during the procedure and postoperative recovery period. Currently, NIRS is used in many centers as the primary cerebral monitor during carotid surgery, not only for decision-making about the placement of a shunt but also to manage systemic physiological variables in order to optimize cerebral perfusion and oxygenation. In this chapter, we present the literature related to NIRS and its practical use, evaluation and reliability for the detection of clamping ischemia and in the prevention of clamping-related neurologic deficits. However, there is a need for large scale randomized trials to support these observations.

BIOGRAPHICAL SKETCH

Prof. Dr. Esma R. Isenovic

Affiliation:

Vinca Institute of Nuclear Sciences, University of Belgrade, Laboratory of Radiobiology and Molecular Genetics, Mike Petrovica Alasa 12-14, Belgrade, Serbia

Education:

- Post-doctoral fellow. Hypertension and Research Division, Henry Ford Hospital, Detroit, Michigan, USA; 1998-2000.

- Post-doctoral visiting scientist , Metabolic Research Unit, University of California, San Francisco, CA, USA; 1997-1997.
- Ph.D. (Molecular Biology), Faculty of Biology, University of Belgrade, Yugoslavia; 1992-1996.
- M.Sci. (Molecular Biology), Faculty of Natural Sciences and Mathematics, University of Belgrade, Yugoslavia; 1987-1992.
- B.Sc. (General Biology), Faculty of Natural Sciences and Mathematics, University of Belgrade, Yugoslavia; 1982-1987.

Business Address:

Vinca Institute of Nuclear Sciences, University of Belgrade, Laboratory of Radiobiology and Molecular Genetics, Mike Petrovica Alasa 12-14, Belgrade, Serbia

Research and Professional Experience:

- Visiting Professor, University of St Andrews, School of Medicine, St. Andrews, Scotland, UK, 2013-2013.
- Visiting Professor, The Pharmaceutical Research Institute at Albany, Albany College of Pharmacy and Health Sciences, One Discovery Drive, Rensselaer, New York 12144, 2010-2010.
- Visiting Professor , CNRS UMR 7131 & Univ Pierre and Marie Curie, Hôpital Broussais, Paris, France; CNRS UMR 7131 & Univ Pierre and Marie Curie, Hôpital Broussais, Paris, France ; 2006., 2007., 2008., 2009., 2012.
- Visiting Professor, CNRS UMR 7131 & Univ Pierre and Marie Curie, Hôpital Broussais, Paris, France;.
- Visiting scientist, Institute of Pathological Physiology, University of Ljubljana, Laboratory for Neuroendocrinology- Molecular Cell Physiology, Ljubljana, Slovenia; 2005-2005.
- Tenure-track position-Associate Professor (Research), Institute Vinca, Belgrade, Department for Radioisotopes, Serbia; 2004-2006. Research Assistant Professor, Principal Research Scientist, Department of Medicine, SUNY-HSC at Brooklyn, Brooklyn, NY, USA; 2000-2003.
- Tenure-track position-Assistant Professor (Research), Institute Vinca, Department for radioisotopes, Belgrade, Serbia; 1998-2003.
- Research Scientist, Institute Vinca, and Department for molecular biology and endocrinology, Belgrade, Serbia; 1998-2000.
- Postgraduate fellowship, Centre International de Formation en Biotechnologie, Bussières-Badil, France, 1990-1990.

Professional Appointments:

- Visiting Research Professor, The Pharmaceutical Research Institute at Albany, Albany College of Pharmacy and Health Sciences, One Discovery Drive, Rensselaer, New York 12144, 2014-current
- Director of Laboratory for Molecular genetics and Radiobiology, Institute Vinca, University of Belgrade, Belgrade, Serbia, January 2014-current

- Professor of Biochemistry (tenure), Faculty of Stomatology in Pančevo, University Business Academy, Novi Sad, Serbia, 2014- current
- Associate Dean for Science, Faculty of Stomatology in Pančevo, University Business Academy, Novi Sad, Serbia, 2014-current
- Deputy Director of Institute Vinca, Belgrade, Serbia, January-December 2013.
- Professor of Molecular Endocrinology, Course for Doctoral students, Faculty of Biology, University of Belgrade, 2012-current
- Professor (Research) Institute Vinca, 2007-current
- Visiting Research Assistant Professor, University of Illinois at Chicago, Department of Medicine, Chicago, USA, 2006–2007
- Tenure position-Professor (Research), Head of Laboratory for Endocrinology, Hypertension and Metabolic Diseases, Institute Vinca, Department of Molecular genetics and radiobiology, Belgrade, Serbia; 2007.- current.
- Associate Professor of Research; Institute Vinca Belgrade, 2004-2006.
- Assistant Professor of Research Department of Medicine, SUNY-HSC at Brooklyn, Brooklyn, NY; 2000-2003.
- Instructor for Biochemistry Course, Faculty of Natural Science, Group for Molecular Biology, University of Belgrade, Yugoslavia 1986-1987.
- Teaching assistant for Biochemistry Course, Faculty of Natural Science, Group for Molecular Biology, University of Belgrade, Yugoslavia; 1986-1987.

Honors:

- Award for the best senior scientist in 2015. Institute Vinca, University of Belgrade
- Deutscher Akademischer Austauschdienst-DAAD Fellowship, 2011.
- The first prize –The best presentation of the best technological innovation. Ministry of Sciences Serbia; 2008.
- Award for the workshop-Training-Planning of Business, Republic of Serbia; 2006.
- Competency based Economies through Formation of Enterprise (CEFE) supported by German Center for Technical Cooperation-Award for CEFE training-Manager (completed 1st module of training), 2005.
- European co-operations in the field of scientific and technical research-COST. Grant Award for short-term scientific mission (STMS), 2005.
- NIH postdoctoral fellowship. NIH, USA; 1998.
- Foundation for Open Society “George Soros “International Conference of Biochemistry and Molecular Biology, San Francisco, CA; Travel Award, 1996.
- International Center for Genetic Engineering and Biotechnology, China National Center for Biotechnology, Development, Beijing, China; Scholarship for postgraduate education, 1995.
- Centre International de Formation en Biotechnologies, Bussiere-Badil, France; Scholarship for postgraduate education, 1990.

Publications Last 3 Years (2015-2017):*Chapters:*

- (1) Ivana Resanovic, Milan Obradovic, Julijana Stanimirovic, Desanka Cenic-Milosevic, Branislava Vukovic, Djordje Radak, Esma R. Isenovic (2017): Nitric oxide and abdominal aortic aneurysm, in book: *"Advances in Medicine and Biology"* (Editor: Leon V. Berhardt), Volume 119, p. 219-248. ISBN: 9781536111057 Nova Science Publishers Inc. New York.
- (2) Milan Perovic, Miroslava Gojnic Dugalic, Milan Obradovic, Esma R. Isenovic (2017): Ultrasonography: contemporary and supplementary screening method for gestational diabetes, in book: *"Gestational Diabetes: Risk Factors, Management and Outcomes"* (Editor: Irene Coleman), p117-p134, ISBN:978-1-53610-786-9, Nova Science Publishers Inc, New York.
- (3) Mohamed Abdel Aleem Haidara, Milan Obradovic, Emina Sudar-Milovanovic, Anastasija Panic, Milan Perovic, Desanka Cenic-Milosevic, Ema Aleksic, Jasmina Milic, Hanaa Zaki Yassin, Bahjat Al-Ani, and Esma R. Isenovic (2017): The Protective Effects of the Primary Female Sex Hormone Estradiol, in book: *"Estradiol: Synthesis, Functions and Effectiveness"* (Editor: Lindsey Henderson), 33-68, ISBN 978-1-53612-322-7. Nova Science Publisher Inc, New York.
- (4) Milan Obradovic, Julijana Stanimirovic, Anastasija Panic, Bozidarka Zaric, Esma R. Isenovic (2016): Na^+/K^+ -ATPase, Sodium/potassium-adenosine triphosphatase, in book: *"Encyclopedia of Signaling Molecules"*, 2nd Edition, (Editor: Sangdun Choi); p-1-6, ISBN-978-1-4614-6438-9; Springer, New York.
- (5) Andreja Trpkovic, Milan Obradovic, Nina Petrovic, Radoslav Davidovic, Emina Sudar-Milovanovic, Esma R. Isenovic (2016): CRP, C reactive protein, in book: *"Encyclopedia of Signaling Molecules"*, 2nd Edition, (Editor: Sangdun Choi); p 1-5, ISBN-978-1-4614-6438-9, Springer New York.
- (6) Milica M. Labudović Borović, Milan M. Obradović, Jelena T. Kostić, Ivan V. Zaletel, Dejan G. Milašinović, Marija Stojanović, Slavica S. Mutavdžin, Milena Vesković, Dragan Opačić, Dejan Radaković, Nela S. Puškaš, Tatjana S. Radosavljević, Saša D. Borović, Zvezdana Z. Kojić, Ljiljana Šćepanović, Božidarka Zarić, Esma R. Isenović (2016): Myocardial Na^+/K^+ -ATPase and SERCA: Clinical and Pathological Significance From a Cytological Perspective, in book: *"Regulation of Membrane Na, K ATPase"* (Editors: Sajal Chakraborti and Naranjan S. Dhalla) under the Series *"Advances in Biochemistry in Health and Disease"*, p. 113-144. ISBN 978-3-319-24748-9, Springer, New York.

ABSTRACT

The term multimodal analgesia refers to the simultaneous use of multiple analgesic methods or drugs. Pain from surgery has three major components: tissue injury, nociceptor stimulation, and activation of central pathways. Because of these integrated processes, a multimodal approach typically deploys interventions such as local anesthesia, a nonsteroidal anti-inflammatory drug, or an opioid so as to achieve a combination of analgesic chemotherapy.

Keywords: preemptive analgesia, multimodal analgesia, adjuvants

KEY POINTS

1. Thoracic epidural analgesia (T6-T11) still remains the gold standard for postoperative pain control in patients undergoing open bariatric surgery.
2. Patients scheduled for gastric bypass surgery or sleeve gastrectomy are often enrolled in an opioid free regimen. This protocols combine several non-opioid analgesic treatments in order to eliminate, or at least minimize opioid dosing. In the case of laparoscopic bariatric surgery this works remarkably well.
3. These regimens include drugs that can stabilize the sympathetic nervous system, including alpha-2 agonists (clonidine and dexmedetomidine), locoregional

anesthetics given intravenously (lidocaine or procaine), magnesium, and gamma-aminobutyric acid modulators (gabapentin).

4. Regional techniques may also play an important role. A transversus abdominis plane block is an efferent block of the anterior abdominal wall that could reduce pain when employed in the context of multimodal analgesia.
5. Other components of the analgesic schemes for bariatric surgery are: ketamine, acetaminophen, NSAID's and glucocorticoids.
6. If an opioid must be used, it is recommended to use small doses of short-acting opioids such as alfentanil or fentanyl.

INTRODUCTION

Morbid obesity increases the risks of anesthesia and surgery including cardiovascular, thromboembolic, pulmonary, and gastrointestinal impairment. Obesity also carries an increased risk of postoperative hypoxemia and complex management issues, which may contribute to the difficulty of pain treatment. It is important for this population to ambulate soon after their surgery. By encouraging this patient population to move their legs, sit up, and stand, we can reduce the risk of postoperative complications.

In this chapter, we describe the multimodal, evidence-based and procedure-specific analgesic regimens which should be the standard of care, with the aim to achieve optimal analgesia with minimal side effects to facilitate the achievement of ERAS objectives (early mobilization and feeding).

INTRAOPERATIVE PERIOD

Using a unimodal pain treatment method, it may be difficult to attain adequate analgesia without inhibiting normal functions (movement or gastrointestinal function) or producing other side effects (sedation or nausea) related to large-dose opioid requirements.

Preemptive analgesia (or preemptive antinociception) refers to the concept that blocking neuronal pathways before or during surgery, can reduce or eliminate the hyperexcitability of these pathways and pain memory during recovery. Preemptive analgesia can be achieved by multiple methods, e.g., infiltrating local anesthetic into surgical wounds. This techniques improves postoperative pain relief and decreases the total opioid requirement, thus reducing undesirable side effects.

Most common side effects of opioids are well known: respiratory depression, pruritus, nausea and vomiting, ileus, constipation, urinary retention, tolerance by desensitization, immediate hyperalgesia that may evolve into chronic pain syndrome, reduced cardiac output, dizziness, somnolence and short-duration central muscle stiffness. Opioid induced ventilatory impairment is well known by anesthesiologists and is easily treated in the post-anesthesia care unit, but this complication is still problematic postoperatively, especially in the bariatric surgery population. Another side effect is pharyngeal muscle weakness, contributing to obstructive breathing patterns in every patient. This side effect should certainly be avoided in obese patients and patients with obstructive sleep apnea (OSA), given the potential for

aggravation and further breathing obstruction. Accordingly recommendations for anesthesiologists are to avoid or minimize the perioperative use of opioids in these patients.

If no opioids are used during surgery, fewer opioids are needed to achieve a pain-free recovery, as addiction has not yet destroyed the mu receptor system. Opioid induced hyperalgesia and chronic pain syndromes are more frequent when high-dose opioids are used perioperatively [1].

- Thoracic epidural analgesia (TEA):

Initiation of neuroaxial blockade before surgery and its maintenance throughout surgery decreases the need for anesthetic agents, opioids and muscle relaxants. Compared with parenteral opioids, epidural blockade has shown to provide better postoperative static and dynamic analgesia for the first 72 h, to accelerate the recovery of gastrointestinal function, to reduce insulin resistance and impact positively on cardiovascular and respiratory complications.

However, it also has side effects like: hypotension, urinary retention, pruritus and motor blockade. Although detrusor function can be impaired in patients receiving this technique, it has been shown that early removal of a urinary catheter (on postoperative day 1) does not increase the risk of bladder recatheterization and urinary infection.

The same benefits have not been observed after laparoscopic procedures, especially in a context of an ERAS program. However, thoracic epidural analgesia might still be valuable in patients at risk of respiratory complications, or in those with high probability of conversion to laparotomy.

- Continuous wound infusion:

Continuous wound infusion of local anesthetic after open abdominal surgery has been shown to improve postoperative analgesia and reduce opioid consumption. Regarding laparoscopic abdominal surgery, it has been demonstrated that pain intensity was similar among patients receiving epidural and wound infusion of local anesthetic.

Despite these promising results, there are several aspects related to this techniques which need to be clarified. It remains to be established if the analgesic effect observed in these trials is mainly driven by the bolus of local anesthetic given at the end of surgery or by the infusion of local anesthetic during the postoperative period.

- TAP block:

Significant reduction of pain intensity and opioid consumption after ultrasound-guided single-shot TAP block has been observed but it is limited to the first 24 hours after surgery. TAP blocks can also be performed by surgeons from the peritoneal cavity before closing the abdominal wall, or laparoscopic guided. Only few studies have reported a reduction of some of the opioid side effects, but these results have not been reproduced consistently.

Optimal timing, choice of local anesthetic, dosing and volumes remain unknown. However, it seems that a minimal volume of 15 ml is required to achieve satisfactory

analgesia with single-shot TAP block. Ropivacaine 0.2% (8–10 ml/h) can be infused for 48–72 h through a multihole catheter.

- Intraperitoneal local anesthesia:

It has been shown to improve postoperative analgesia, reduce shoulder pain and opioid consumption after laparoscopic gastric surgery.

- Opioids:

The primary objective should be to minimize or avoid the use of opioids wherever possible. Under general anesthesia, patients are unconscious and do not perceive pain. Although there is no pain perception, surgery induced activation of nociceptive reflex arcs has hemodynamic consequences. Using opioids to reduce the hemodynamic changes should be resisted as much as possible, as hyperalgesia can develop acutely and opioid-related side effects can occur at very low doses.

Control of blood pressure and heart rate at intubation and during surgery by beta-blockers, calcium channel blockers, or lidocaine should be encouraged rather than using opioids without a specific indication other than intraoperative tachycardia or hypertension [4].

- Multimodal analgesia:

A multimodal analgesia regimen is based on routine use of NSAID's and paracetamol (PO or intravenously). It should be adopted if not contraindicated in patients undergoing open or laparoscopic bariatric surgery with the aim to reduce opioid consumption and their dose-dependent side effects that impair recovery.

Acetaminophen (paracetamol) has shown to improve postoperative analgesia, have an opioid-sparing effect, but not to reduce opioids side effects.

Concerns have been raised about the cardiovascular risk and delayed bone healing associated with the use of NSAID's and COX-2 inhibitors. The evidence is inconclusive and does not support the avoidance of short perioperative treatment in patients with low cardiovascular risk.

High-dose of systemic steroids have also shown promising results, when used carefully in patients undergoing gastrointestinal surgery. Perioperative intravenous ketamine and gabapentinoids have also shown opioid sparing properties. However, the risk of side effects such as dizziness and sedation should be considered.

Gabapentin or pregabalin should be considered as part of a multimodal analgesia protocol. Both medications are associated with reduced opioid requirements and appear effective when administered as a preoperative dose. It is difficult to determine optimal doses, because higher doses might be more effective, but they might also be associated with more sedation. They are only available in oral form, potentially limiting their use in the immediate postoperative period. Dose reductions are recommended in patients with impaired renal function.

Intravenous ketamine has been evaluated as a part of multimodal analgesia. It has been found in several studies that ketamine IV infusions were associated with decreased

postoperative pain medications use compared with placebo, and with a decreased risk of persistent postsurgical pain. If administered perioperatively, ketamine is associated with increased risk of hallucinations and nightmares.

Glucocorticoid steroids may have analgesic properties possibly related to anti-inflammatory properties and should be considered as part of a multimodal perioperative pain protocol. The concern for significant hyperglycemia (>180 mg/dL) in bariatric patients has not been confirmed [3].

Dexmedetomidine is a highly selective α_2 -agonist. It is approximately 8 times more specific to α_2 adrenergic receptors than clonidine and its elimination half-life is much shorter. This medication should be administered cautiously as several cardiovascular effects may occur. For example, dexmedetomidine should be given over at least 10 minutes, as hypertensive episodes may otherwise be provoked. Nonetheless, a generally hypotensive effect of dexmedetomidine (as well as clonidine) may be observed later as well. In addition, bradycardia may commonly occur, and even cases of asystole have been reported. Importantly, the use of dexmedetomidine is contraindicated in patients with higher degree AV-blocks. While there are certainly many benefits associated with the use of dexmedetomidine in the perioperative setting, caution is required [6].

- Intravenous lidocaine:

In view of its antinociceptive and anti-inflammatory properties, systemic administration of lidocaine as adjuvant to systemic opioids has been shown to improve postoperative analgesia, reduce opioid consumption and speed surgical recovery.

Side effects are directly related to serum levels, and are more pronounced in patients with liver dysfunction, pulmonary diseases when the predominant problem is carbon dioxide retention, and congestive heart failure [4].

INTRAOPERATIVE CLINICAL MANAGEMENT

Gabapentin 150–300 mg can be given as premedication orally and continued the next day postoperatively, when the patient can take oral medication. Dexmedetomidine loading dose of 0.25 $\mu\text{g/kg}$ is given 15 minutes before induction. The dose is further increased to 0.5 or 1 $\mu\text{g/kg}$ and continued with 0.5–1 $\mu\text{g/kg/h}$, if the procedure takes longer than two hours. Rapid awakening requires the use of the lowest possible dexmedetomidine dose (<0.5 $\mu\text{g/kg}$), frequently without maintenance doses.

Clonidine has a much longer half-life and is therefore less suitable for short procedures.

Lidocaine 1.5 mg/kg and magnesium 40 mg/kg given at induction and by infusion (lidocaine or procaine 1–3 mg/kg/h and magnesium 5–15 mg/kg/h) further improve the multimodal approach.

Ketorolac (0.5 mg/kg) or diclofenac (150mg) and dexamethasone (10 mg) should be administered before surgery to reduce inflammation. The use of propofol combined with a sympathetic block is possible but requires high propofol doses, while inhalational anesthetics can be given below one minimum alveolar concentration value.

Most of these doses are calculated for lean body weight or ideal body weight +20%, which is easier to calculate instead of total body weight [1].

POSTOPERATIVE CLINICAL MANAGEMENT

Epidural blockade should be tested before surgery or in the immediate postoperative period to avoid non-functioning epidurals and unnecessary opioid administration. The addition of opioids to local anesthetic has shown to improve postoperative analgesia. Although epidural solution containing morphine increases the risk of urinary retention.

However, the use of low dose of local anesthetics (bupivacaine 0.1 mg/ml) and lipophilic opioids (e.g., fentanyl) seem to provide optimal analgesia with minimal side effects. Epidural morphine in adjunct to local anesthetic can be preferred to lipophilic opioids to increase segmental analgesia spread and could be recommended for long midline incisions. Epidural infusions can be continued for 48-72, gradually reducing infusion rates and until the recovery of gastrointestinal function.

Adding adrenaline (1.5–2.0 lg/ml) to epidural mixture of local anesthetic and fentanyl improves postoperative analgesia, especially during mobilization and coughing, and reduces pruritus and nausea.

Hypotension induced by epidural blockade should be treated with vasopressors as first choice provided the patient is not hypovolaemic. Orthostatic hypotension associated with postoperative epidural analgesia does not impair the ability to ambulate [2].

When waking the patient up, give a loading dose of paracetamol and continue with paracetamol 1gr every 6 hours for several days, if needed. Add a non-steroidal anti-inflammatory drug (NSAID) such as diclofenac (75 mg every 12 hours) for up to the first two days. Continue with oral gabapentine (150-300 mg / day) when possible.

Continue the sympathetic block by loading up with an extra dose of clonidine (75-150 µg), lidocaine 1 mg/Kg, and ketamine 25 mg at the end of anesthesia if not already done.

It is better to keep giving these in a continuous infusion bag or pump over the next 10-24 hours. Medication choices for infusion include clonidine (0,1 µg/Kg/h) or dexmedetomidine (0,1 µg/Kg/h), ketamine (0,05 mg/Kg/h) and magnesium (5 mg/Kg/h).

Dexmedetomidine and procaine are shorter acting and therefore preferable. A continuous infusion of dexmedetomidine, magnesium, ketamine or lidocaine might require follow-up on a high dependency care unit.

The exact duration of the lidocaine infusion providing optimal analgesia and facilitating also recovery remains unknown. Systemic toxicity is rare, but continuous cardiovascular monitoring is required.

Be aware that although most of these drugs are given postoperatively below sedation levels, dose reduction may be required if residual sedation persists postoperatively in older and frail patients [1].

OPIOID ANALGESIA

Although one of the main analgesic goals for the bariatric surgery today is minimization of opioid use, one must recognize that opioids are still an important analgesic option. However, their role is less central when compared to traditional care where opioids were the main analgesic options for postoperative pain management.

For opioid-naïve patients who are not yet tolerating oral intake, patients ideally would have one of the main local anesthetic based options and multimodal analgesia before utilizing short-acting IV opioids for rescue analgesia. After these, opioid-naïve patients are tolerating oral intake, then short-acting oral opioids can be added for breakthrough pain after a scheduled regimen of nonopioid analgesics such as gabapentin, acetaminophen, NSAIDs, and other multimodal analgesic agents.

Thus, although some chronic pain patients will benefit from a PCA, the assumption that IV opioids via PCA should be a standard part of postoperative recovery is not necessarily valid in this case, and should be reconsidered [5].

Chapter 452

MULTIMODAL ANALGESIA AND ADJUVANT ANALGESIC TREATMENT IN BARIATRIC SURGERY

Carmen Vallejo Lantero*, MD and Esther García Villabona, MD

Anesthesiology Department, Hospital Universitario de La Princesa,
Madrid, Spain

ABSTRACT

Increasing numbers of patients with morbid obesity are presenting for surgery and their acute pain management requires an evidence-based clinical update. The pathophysiology of obesity, typical co-morbidities and the high prevalence of obstructive sleep apnea make safe analgesic management difficult in these patients. Multimodal, evidence-based and procedure-specific analgesic regimens should be standard of care, with the aim to achieve optimal analgesia with minimal side effects. The perioperative use of non-opioid adjuvants appears to offer further improvements in patient's safety and outcomes.

Keywords: multimodal analgesia, adjuvant analgesics, pain management, bariatric surgery, obesity, postoperative pain, opioid-sparing

INTRODUCTION

With increasing awareness of both short- and long-term problems associated with liberal perioperative opioid administration, the need for routinely and clinically feasible alternatives is greater than ever. Opioids still represent the mainstay of any perioperative analgesic treatment plan. However, opioids can provoke severe side effects. Some of these side effects like postoperative nausea and vomiting (PONV) are obvious; others are not so manifest. Hyperalgesia and postoperative respiratory depression caused by opioids are of concern, yet often go unnoticed. Postoperative desaturation episodes are far more prevalent than generally

* Corresponding Author's Email: c.vallejo_26@hotmail.com.

appreciated, especially in patient groups with specific risk factors like morbid obesity (MO) or obstructive sleep apnea (OSA). Furthermore, undesirable side effects like constipation, urinary retention, and drowsiness may significantly impede an uneventful postoperative course [1].

In the obese patient, the goal of postoperative pain management is provision of comfort, early mobilization and improved respiratory function without causing inadequate sedation and respiratory compromise. The pathophysiology of obesity, typical co-morbidities and the high prevalence of OSA amongst obese patients make safe analgesic management difficult. In particular, pain control after bariatric surgery is a major challenge [2].

In times of ever more ERAS® (enhanced recovery after surgery) protocols emerging, the primary reliance on analgesic agents with such suboptimal side effect profile seems out-of-date. Although an opioid-free anesthesia and analgesia regimen long seemed elusive, newer truly multimodal protocols enable opioid-free (or at least opioid-sparing) anesthesia for certain types of operations. Multimodal, evidence-based and procedure-specific analgesic regimens should be standard of care, with the aim to achieve optimal analgesia with minimal side effects [3]. In patients with MO, these specific outcomes would also not be desirable, they are probably essential.

Though overall evidence is limited, multimodal analgesia with a step-wise, severity-based, opioid-sparing approach appears to improve acute pain management in morbid obesity. The perioperative use of non-opioid adjuvants appears to offer further improvements in patient's safety and outcomes [4].

GOALS OF POSTOPERATIVE ANALGESIA IN MORBID OBESITY

Pain management of the obese patient in the perioperative setting is of great importance for not only the comfort, but also the outcome of patients. After bariatric surgery, pain is the most frequent postoperative problem, even if this surgery was performed laparoscopically. Adequate analgesia provides comfort for patients and this is an important treatment goal, but analgesia should also allow early mobilization, which, in turn, reduces the risk of deep vein thrombosis (DVT), pressure ulcers and respiratory complications including pneumonia [2].

The main risks for this patient group are perceived to be respiratory complications [5]. In MO, conventional opioid-based acute pain during intraoperative and post-operative pain management is associated with the risk of sedation, airway obstruction, and respiratory depression. Site of surgery (bariatric surgery) and co-existing OSA, which is very common in this population, are risk factors contributing to the increased incidence of pulmonary complications in obese patients [6]. Goals of postoperative analgesia should be the ability to comply with respiratory physiotherapy and early mobilization.

MULTIMODAL ANALGESIA IN OBESE PATIENT

The concept of multimodal analgesia was introduced more than a decade ago as a technique to improve analgesia and reduce the incidence of opioid-related adverse events. Multimodal techniques for pain management include the administration of two or more drugs

that act by different mechanisms for providing analgesia. These drugs may be administered via the same route or by different routes.

Multimodal analgesia involves the concurrent use of primarily non-opioid analgesics to take advantage of the additive, if not synergistic, effects that produce superior analgesia while decreasing opioid use and opioid-related side effects. Also, a key component of multimodal pain management is the utilization of regional analgesic techniques, including peripheral and field blocks and neuraxial blocks [7]. Recent data on the efficacy and safety of multimodal pain management strategies for weight loss surgery are consistent with this accepted approach of opioid-sparing postoperative analgesia in the general surgical patient population [8].

The ASA task force on acute pain management in 2012 recommended that multimodal pain analgesia should be included for the management of perioperative pain whenever possible [9]. It is widely accepted adjuvants such as ketamine, lidocaine and pregabalin, directed to avoid acute hyperalgesia, plays a major role in the treatment of acute pain in MO.

ACUTE PAIN MANAGEMENT IN OBESE PATIENT

The role of multimodal analgesia and non-opioid adjuvant therapy has been shown to be beneficial in a variety of procedure-specific postoperative pain management protocols.

Acute pain management modalities can be divided into systemic analgesics and regional anesthesia techniques. The systemic analgesics have been further described as per the World Health Organization (WHO) Step Ladder approach- foundational, intermediate, opioid and adjuvant analgesics. This stepwise, severity based, opioid-sparing approach will be useful in all patients; more so in those with MO.

SYSTEMIC MEDICATIONS

Acetaminophen and NSAIDs

Non opioid analgesics should be considered wherever possible.

- *Acetaminophen* is an important foundational World Health Organization (WHO) Step I whose mechanism of action is still not completely understood. It is highly selective and has an additive and not necessarily synergistic effect when combined with NSAIDs. It has been repeatedly shown to decrease opioid requirements in the perioperative setting and even contribute to shorter length of stay. The half-life of paracetamol does not change in obese patients, and plasma concentration measurements suggest that dosing according to the ideal weight is appropriate. IV acetaminophen is an attractive option in the perioperative period. It can be administered independent of enteral intake. (*Recommendation Grade B*) [4].
- *Ketorolac*. Cyclo-oxygenase inhibitors, as well non-selective NSAIDs such as selective coxibs, are the most widely used component of multimodal analgesia. The non-steroidal anti-inflammatory drugs are highly effective analgesics with the lowest numbers needed to treat (NNT) of all classes. Ketorolac administered regularly post-

operatively can result in lower opioid consumption in patients with MO (*Recommendation Grade C*) [4]. The perioperative use of ketorolac alone or in combination with local anesthesia leads to significant improvement of postoperative pain control [2]. Similarly, an intraoperative infusion of ketorolac reduced pain scores and decreasing the incidence of postoperative nausea and vomiting (PONV).

Further studies of dose, safety and side effects specific to MO are needed.

Intermediate Analgesics: Tramadol and Tapentadol

Tramadol and Tapentadol are both intermediate-potency (WHO Step II) analgesics that may benefit surgical patients due to their multimodal mechanisms of action. Tramadol may be particularly useful when combined with acetaminophen (*Recommendation Grade B*) [4].

The use of tapentadol has not been yet reported specifically in this patient population. This is a newer molecule, related to tramadol but promisingly lacks the serotonergic effects of the latter, so reducing nausea, vomiting and interactions with anti-depressant medications.

Opioids Analgesics

Use of opioids for post-operative pain in patients with MO presents a challenge. Nevertheless, to achieve satisfactory pain control in obese patients after surgery, the employment of opioids is in some cases inevitable. Through the review of the literature base on the evidence available for the management of acute pain on MO, the current recommendations conclude that in case of use of opioid, PCA should be limited to patients with moderate to severe postoperative pain, probably when oral opioid therapy is not possible. Basal or continuous opioid infusions in patients with MO and particularly those with undiagnosed or untreated OSA should be avoided. Patients with suspected sleep disordered breathing must be observed with overnight monitoring of respiratory adequacy, during the entire time PCA is used (*Recommendation Grade C*) [4].

Adjuvants Analgesics

Gabanoids: Pregabalin/Gabapentina

Gabanoids, gabapentin and pregabalin, are anticonvulsants but are also called neuromodulators, as they reduce neuronal excitability by inhibiting the α -2- δ subunit of calcium-gated channels on presynaptic axons. Both of them plays a role as a component of multimodal analgesia in non obese patients. In MO patients, single preoperative administration of 150 mg pregabalin resulted in improved analgesia, opioid-sparing and reduced adverse effects such as nausea and vomiting [2]. Similarly, preoperative administration of 100 mg of gabapentin also produced significantly lower pain scores in recovery with less nausea-vomiting compared with placebo. However, pregabalin and gabapentin may be associated with increased sedation and postoperative respiratory depression.

There is no consensus for dose, frequency or duration treatment. Their use in the perioperative period requires careful assessment of the risk-benefit in patients with MO and/or OSA (*Recommendation Grade C*) [4].

Nevertheless, although several single clinical trials report that gabapoids decrease the postoperative use of opioids, the Pfizer multi-centric phase III program failed to confirm these findings and to demonstrate any effectiveness in three different models. Nevertheless, the use of gabapoids for acute pain is extensive, even if it is not an approved indication. Recently, the non-approved use of gabapoids has been questioned [7].

NMDA Antagonist

With the discovery of the N-methyl-D-aspartate (NMDA) receptor and its links to nociceptive pain transmission and central sensitization, there has been renewed interest in utilizing noncompetitive NMDA receptor antagonists as potential antihyperalgesic agents.

Ketamine, magnesium, methadone, and dexamethasone all have NMDA-blocking ability, but ketamine has emerged as a frontrunner in the perioperative period [7].

- *Ketamine* has been a well known general anesthetic and analgesic drug. A review of available trials concluded that ketamine alone or added to morphine/hydromorphone showed mild improvement in postoperative analgesia while reducing opioid requirements along with reducing postoperative nausea and vomiting (PONV) [10]. An IV bolus before incision and then a continuous infusion is an effective option for postoperative pain control. If the infusion is administered over a prolonged period of time (48 hours) for more invasive and routinely painful procedures, patients can be at lower risk for developing persistent postoperative pain in the subsequent months. Low doses of ketamine (0,1-0,5 mg/kg) used in morbid obese lead to a significant reduced opioid consumption and reduced need for rescue analgesia importantly (*Recommendation Grade C*) [4]. Limiting factors for ketamine are co-existing severe arterial hypertension and cardiac failure, although the induction of hypertension by low-dose ketamine is unlikely.
- *Magnesium*: The magnesium ion was the first agent discovered to be an NMDA channel blocker. At very high doses, perioperative intravenous magnesium sulfate has been reported to reduce postoperative morphine consumption but not postoperative pain scores. However, as the magnesium ion crosses the blood-brain barrier poorly in humans, it is not clear whether the therapeutic effect is related to the NMDA antagonist effect studied in the central nervous system [11].

Alpha-2 Adrenergic Agonists

Alpha-2 adrenergic activation represents an intrinsic pain control network of the central nervous system. In bariatric surgery it was demonstrated that the use of alpha2-agonists leads to a reduction in postoperative opioid consumption, less respiratory depression, shorter PACU stay, less use of antiemetics, and a favourable cardiovascular stability.

- *Dexmedetomidine* is an α 2 receptor agonist with sedative and analgesic sparing properties. Various studies in MO population have shown safety of dexmedetomidine infusion perioperatively and the capacity to minimize narcotic requirements, length

of stay after laparoscopic bariatric procedures and the risk of developing PONV (*Recommendation Grade B*) [4,12].

- *Clonidine*. Due to the many side effects of systemic clonidine administration (hypotension, bradycardia, and sedation), the spinal route is preferred. When clonidine is used as a premedication, it has found to be more sedating and associated with bradycardia and hypotension. Clonidine has been used in a limited number of studies in patients with MO.

When comparing pain scores, quantity of analgesic consumption, PONV and patient satisfaction, a single study reported comparable benefits between clonidine and dexmedetomidine [4]. Up to date it remains unclear if there is a clinical difference between the two substances, of which dexmedetomidine possesses a much higher specificity of the alpha2-adrenoceptor. Optimal dosing strategies are lacking providing the best balance between perioperative analgesia, patient safety, and quick recovery. Nonetheless alpha2-agonist appear to be one of the most tempting tools in the anaesthesiologist's arsenal to reduce perioperative opioid consumption [11].

Lidocaine

Lidocaine has analgesic effect, anti-hyperalgesic and anti-inflammatory properties, which makes it use as a general anesthetic adjuvant. Lidocaine is capable of reducing nociception and/or cardiovascular responses to the surgical stress, and postoperative pain and/or analgesic requirements. If the exact mechanism of action remains not fully explained; bolus then continuous lidocaine infusion has clear analgesic benefits. Lidocaine is one of major drug for opioid reduced anesthesia (ORA) or opioid free anesthesia (OFA) procedures. It clearly improves the postoperative outcomes with increased patient satisfaction. Such procedure takes place wisely in the ERAS protocols [13]. With recommended protocols, safety will be as great as his efficacy. Very little information is available in patients with morbid obesity indicating a significant decrease in opioid consumption in PACU and at 24 hours post analgesia regimen (*Grade B*) [4], but few studies are available and optimal dosing schedule in patients with morbid obesity is yet to be determined..

REGIONAL TECHNIQUES

Utilizing regional anesthesia to block peripheral or central nerves is an effective option to reduce or eliminate the need for opioids. A continuous infusion of local anesthetics should be considered in patients requiring prolonged analgesia, who are at risk of local anesthetic overdose, and in whom motor function needs to be preserved, like patients undergoing lower extremity joint replacement. Other benefits of continuous nerve block include reduction in hospital resource utilization, decreased risk of nausea and vomiting, early discharge, and improvement in patient satisfaction.

Neuroaxial Techniques

Neuroaxial techniques for pain management have been shown in numerous studies to be highly efficient in reducing opioid-related complications.

Thoracic Epidural Analgesia (TEA)

(T6-T11) remains the gold standard for postoperative pain control in patients undergoing open abdominal surgery. Initiation of neuroaxial blockade before surgery and its maintenance throughout surgical intervention decreases the need for anaesthetic agents, opioids and muscle relaxants [3]. Continuation of regional anesthesia techniques into the postoperative period to provide analgesia is regarded particularly useful in obese patients undergoing open bariatric surgery. Compared with parenteral opioids, epidural blockade has shown to provide better postoperative static and dynamic analgesia for the first 72 h, to accelerate the recovery of gastrointestinal function, to reduce insulin resistance and impact positively on cardiovascular and respiratory complications [3]. Epidural analgesia in patients submit to open bariatric surgery resulted in better pain scores, patient satisfaction, early recovery and ambulation (*Recommendation Grade B*) [4]. The same benefits have not been observed after laparoscopic procedures, especially in a context of an ERAS programme. However, TEA might still be valuable in patients at risk of respiratory complications, in those with high probability of conversion to laparotomy, or requiring transverse or Pfannenstiel-like incisions [3].

Intrathecal (IT) Analgesia

IT morphine is a valuable analgesic technique to improve early postoperative analgesia and facilitates surgical recovery. However, compared with systemic opioids, the incidence of pruritus and respiratory depression (although rare) is increased. Postoperative urinary retention is also more frequent. In the light of these side effects, in the context of an multimodal analgesic regimen other regional anaesthesia technique could be favoured [3].

TAP Blocks

Transversus abdominis plane (TAP) block has been studied as a potential technique to aid with pain management in bariatric surgery. Field blocks are non-specific, and the local anesthetic mixture is administered in fascial planes between muscles. It has been shown to reduce morphine use and PONV in abdominal surgery (*Recommendation Grade C, especially laparoscopic procedures*) [4]. Other studies have found limited or no statistically significant difference in outcomes with this block. One potential explanation may be that, there is no significant added benefit of TAP block if local anesthetic is also infiltrated at trocar insertion sites. Like all regional techniques, the efficacy of TAP block is also operator dependent, and in patients with morbidly obesity the performance of TAP blocks may be more difficult. However, TAP blocks can also be performed by surgeons from the peritoneal cavity before closing the abdominal wall, or laparoscopic guided.

Intraperitoneal and Wound Modalities

Continuous administration of local anesthetic has been reported at wound and/or intraperitoneal infusions.

Some studies that examines the use of continuous bupivacaine wound infusion in laparoscopic weight loss surgery (WLS) lasting up to 96 hours. There was a statistically significant decrease in opioid consumption, but this benefit was not sustained beyond the infusion and there was no improvement in patient pain scores.

On the other hand, intraperitoneal bupivacaine infusions have found a statistically improvement in pain scores and total opioid consumption. Likewise, the use of a one-time spray of bupivacaine applied at the esophageal hiatus once the pneumoperitoneum is established, resulted in statistically significant decreased in analgesic consumption, including shoulder tip pain. For these reasons, these loco-regional analgesic modalities contribute to optimizing pain in open abdominal and laparoscopic surgical procedures (Recommendation Grade C). Further investigations, standardization and technique refinement are required [4].

CONCLUSION

A multimodal analgesia regimen should be used in patients undergoing open and laparoscopic abdominal procedures with the aim to reduce opioid consumption and their dose-dependent side effects that impair recovery. Analgesic techniques should aim to not only provide optimal pain control, but also to facilitate the achievement of important milestones such as early mobilization. This is of particular importance in this patient population because of the risks of airway obstruction and respiratory insufficiency, otherwise inherent to an opioid-centric acute pain management protocols. Opioid-sparing analgesic strategies, including regional analgesia techniques, should be implemented in a context of a multimodal analgesic regimen [3].

Chapter 453

IMPLICATIONS OF LAPAROSCOPIC APPROACH ON POSTOPERATIVE PAIN AFTER BARIATRIC SURGERY

Pablo Priego*, MD, PhD

Department of General Surgery, Division of Esophagogastric and Bariatric Surgery,
Ramón y Cajal University Hospital, Madrid, Spain

ABSTRACT

Laparoscopy has shown to have special benefits to obese patients because of less blood loss, earlier mobilization, reduced postoperative pain, shorter hospital stay and faster convalescence in comparison with the open procedure. Moreover, the risk of intraabdominal adhesions and incisional hernia has cleared decreased. Pain management is a significant component of postoperative care. The traumatic effect of the surgical incision, the mobilization of intraabdominal viscera during surgery, and some of the metabolic responses that accompany surgery are the main responsible in the occurrence of postoperative pain and complications. Implications of laparoscopic approach against open procedure on postoperative pain after bariatric surgery are presented in this chapter.

Keywords: open, laparoscopy, bariatric surgery, postoperative pain, analgesia, gastric bypass

INTRODUCTION

The number of bariatric procedures has recently risen up, not only because an increase of the number of obese patients, but also because of the exponential growth up in the number of laparoscopic surgeries performed. In USA, Nguyen et al., [1] using NIS data estimated that the percentage of bariatric procedures performed laparoscopically increased from 2.1% in 1998 to 17.9% in 2002. Nowadays, it is not very common to perform a bariatric surgery through an open approach.

Laparoscopy has shown to have special benefits to obese patients because of less blood loss, earlier mobilization, reduced postoperative pain, shorter hospital stay and faster convalescence in comparison with the open procedure. Moreover, the risk of intraabdominal adhesions and incisional hernia has clearly decreased [2].

However, when comparing the outcomes of a bariatric operation performed by two different approaches, it is essential to choose which outcome measures are determinant for clinical practice. Nguyen et al., [3], argue that sometimes, the most common measurements outcome include operative time and length of hospital stay. Furthermore, and although a short surgical time is preferred, this is not always correlated with a better operative outcome. In the same way, the hospital stay can be misleading because it only represents the time of hospitalization that it is considered to be safe before a patient is discharge home. For these reasons, these two parameters would not be as good enough in order to show the superiority to one technique over the other. From the patient's view better measures will be the postoperative pain and duration of the convalescence.

Pain management is a significant component of postoperative care. The traumatic effect of the surgical incision, the mobilization of intraabdominal viscera during surgery, and some of the metabolic responses that accompany surgery are the main responsible in the occurrence of postoperative pain. Moreover, postoperative pain may also be a pointer to the development of certain complications like atelectasia, pneumonia, deep vein thrombosis, pulmonary embolism and cardiovascular events [4].

Implications of laparoscopic approach against open procedure on postoperative pain after bariatric surgery are presented in this chapter.

OPEN VS. LAPAROSCOPIC BARIATRIC SURGERY

Since the introduction of laparoscopic surgery, a wide variety of techniques have been performed via this approach because of the advantages it offers, i.e., earlier mobilization, reduced postoperative pain, shorter hospital stay, better cosmetic results and faster convalescence in comparison with the open procedure. Moreover, the risk of intraabdominal adhesions and incisional hernia has clearly decreased [2].

Therefore, surgeons began using the different techniques that existed for treating obesity through the laparoscopic approach [5, 6]. *Gastric banding* was the first laparoscopic technique described which became extremely popular due to its relatively low technical difficulty and low initial morbidity and mortality rates [7-9]. However, long-term results regarding weight loss and late complications were worse than with other bariatric procedures.

Another of the procedures performed via laparoscopy was *Vertical banded gastroplasty* [10, 11]. This technique was not difficult to perform by laparoscopy and had low morbidity and mortality rates, but the long-term results were worse than with gastric bypass and nowadays it is not a common option for treatment of obese patients, due to the discomfort it causes the patient and the high incidence of staple-line disruption.

Gastric bypass (GB) was initially developed in USA by Masson and Ito in the 1960s [12]. Although GB resulted in durable weight loss and had evident advantages like better weight loss than after purely restrictive procedures, low incidence of protein-calorie malnutrition, rapid improvement of resolution of weigh-related comorbidities and appetite

reduction; postoperative pain and wound-related complications such as infection (8%) and incisional hernia (20%) were disgusting problems.

Laparoscopic gastric bypass (LGBP) was first introduced by Wittgrove et al., [13] in 1994 and since then has become more commonly performed than open gastric bypass (OGB).

Although there are several restrictive (gastric band, sleeve gastrectomy) and malabsorptive weight loss operations (duodenal switch, SADI-s, biliopancreatic diversion...), most of studies comparing open vs. laparoscopic approach are related to GB, because nowadays it is the most common bariatric procedure all around the world.

From the beginning, clinical studies [6, 14, 15] demonstrated that LGBP was a safe and effective alternative to OGB for the treatment of morbid obesity. Moreover, laparoscopy showed a lot of advantages against the traditional open approach. On the other hand, LGBP showed that this was a complex operation associated with a long learning curve and with a possible increase in the rate of internal hernia [16-18].

Most part of studies that compare open vs. laparoscopy in bariatric surgery are too old (final of the 90s and beginning of 21st century), because nowadays, there is not discussion about the advantages of this minimally invasive approach in the treatment of these obese patients. Indeed, current studies are concerning about differences in postoperative pain and cosmetic results between the single-port and the traditional laparoscopic approach [19, 20]. Other studies present that the implementation of Enhanced Recovery After Surgery (ERAS) programs [21] in treatment of obese patients is a safe issue, obtaining similar results to standard care in terms of complications, reoperations, mortality and readmissions; with less postoperative pain and earlier hospital discharge. Other studies are referred to the decrease of postoperative pain associated with the intraoperative peritoneal infusion with ropivacaine [22] and the postoperative advantages of free opioids anesthesia [23]. However, these items have been described in other chapters of the book.

In order to understand differences between open and laparoscopic approach in bariatric surgery, it is essential to differentiate some technical aspects that are going to affect clinical outcomes [3].

The first difference between these two approaches is the method of access (length and number of abdominal incisions). OGB is usually performed through a supraumbilical midline incision, whereas LGBP is performed through five-six small abdominal incisions for trocars.

Second difference is the method of exposure. During OGB, the methods of exposure are abdominal wall retractors and mechanical retractors of intraabdominal organs. On the other hand, in LGBP, methods of exposure are the pneumoperitoneum to create a working space and gravity for moving of intraabdominal organs.

Finally, the last difference is the extent of operative trauma. By reducing the length of the surgical incision and avoiding the needed of abdominal wall retractors, it is logical that operative trauma is less in after LGBP in compare to OGB.

Although physiopathological basis of postoperative pain have been presented in Chapter 1, we cannot avoid that there are some physiopathological differences between open and laparoscopic surgery that influences in the development of postoperative pain.

Surgical injury often results in accumulation of edema (third-space fluid), and the degree of third-space fluid accumulation is often proportional to the extent of surgical trauma. Indeed, intra-abdominal pressure after LGBP is significantly lower than after OGB on postoperative days 1, 2, and 3. Moreover, the magnitude of the systemic stress response (interleukin-6 levels) is significantly lower after LGBP than after OGB.

Providing a high quality pain treatment is a major challenge in health care. Despite the developments in pain management, postoperative pain is still a clinical problem [24-26]. Poorly managed pain reduces quality of life, causes unneeded suffering, and can extend time of discharge from hospital [27]. The importance of evaluating postoperative pain with consideration given to type of surgery and the patient's perspective cannot be overemphasized. Postoperative pain is an important measurement of outcome because it can be measured objectively. The degree of postoperative pain after OGB is associated with the length of the surgical incision, the extent of operative dissection, and operative trauma [26]. Hence, laparoscopic procedures that minimize surgical tissue trauma are associated with less pain than laparotomies [29-30].

While some outcomes such as pulmonary complications, duration of hospital stay and convalescence appear to be better with the laparoscopic approach [31, 32], few prospective trials have investigated the effect of LGBP on postoperative pain and bowel function.

One of the first studies that compare open vs. laparoscopic approach in bariatric surgery was the study of Joris et al., [33]. They compared a group of 30 obese patients undergoing laparoscopic or open gastroplasty (15 in each group). Postoperative pain, measured on a visual analogue scale (VAS), and opioid consumption were recorded during the first two days after operation. Tests of pulmonary function were performed and SpO₂ was measured 4 h after surgery and on days 1, 2 and 3 after operation. Results confirmed that in the laparoscopy group, requirements for postoperative opioid were 50% less; pain intensity during mobilization and on coughing was significantly less after laparoscopy. Forced vital capacity, forced expiratory volume in 1 s and peak expiratory flow rate were reduced significantly less after laparoscopic gastroplasty than after open gastroplasty. Moreover, SpO₂ values were significantly greater in the laparoscopy group.

El Shoraby et al., [34], performed a prospective study in which patients were assigned to LGBP (33 cases) or OGB (20 cases). All patients received patient controlled analgesia (PCA) with intravenous morphine and rectal naproxen 500 mg every 12 hours. Postoperative analgesia was assessed daily using a VAS at rest, on walking and coughing. The amount of morphine used during the first 48 hours, the time of return of gastrointestinal motility and the time until first oral food intake were recorded. Patients undergoing LGBP requested less morphine and showed lower VAS pain scores than patients undergoing OGB. The return of bowel movement in the laparoscopic group occurred 1 day earlier than in the open group. The time to first passage of gas and oral food intake was shorter after laparoscopic than after OGB. Moreover, patients in the laparoscopic group were discharged 1.5 days earlier than patients in the open group.

Fisher [35] randomly selected bariatric surgery patients, consisting of 20 OGB, 19 LGBP, and 21 laparoscopic adjustable gastric banding (LAGB). LAGB patients returned to normal activity levels earlier than gastric bypass patient's irrespective of approach. Moreover, recovering from surgery was significantly sooner than OGB patients. However, perceived differences in recovery time between OGB and LGBP patients did not affect their time to resumption of normal activity.

Finally, Nguyen et al., [3] performed a randomized study in which seventy obese patients were randomly assigned to undergo LGBP (n = 36) or OGB (n = 34). Pulmonary function studies were performed preoperatively and on postoperative days 1, 2, 3, and 7. Oxygen saturation and chest radiographs were performed on both groups preoperatively and on postoperative day 1. Postoperative pain was evaluated using a VAS and the amount of

narcotic consumed was recorded. LGBP patients had significantly less impairment of pulmonary function than OGB patients on the first three postoperative days. By the 7th postoperative day, all pulmonary function parameters in the LGBP group had returned to within preoperative levels, but only one parameter (peak expiratory flow) had returned to preoperative levels in the OGB group. Moreover, on the first postoperative day, LGBP patients used less intravenous morphine sulfate than OGB patients (46 +/- 31 mg versus 76 +/- 39 mg, respectively), and VAS pain scores at rest and during mobilization were lower after LGBP than after OGB. Fewer patients after LGBP than after OGB developed hypoxemia (31% versus 76%) and segmental atelectasia (6% versus 55%). All results were statistically significant.

Recovery is a very important outcome parameter and can be measured by questioning the patients' time to return to activities of daily living. Nguyen et al., [15] reported that LGBP patients had a more rapid return to activities of daily living than OGB patients. Furthermore, and based on the SF-36 health survey and the Moorehead-Ardelt Quality-of-Life questionnaire it has shown that recovery based on physical and social functioning at 1 and 3 months postoperatively was significantly faster after LGBP compared to OGB. In addition, patients undergoing laparoscopic surgery perceived their overall health to be better than that of OGB patients when the survey was measured at 1 month postoperatively. Moreover, LGBP patients had more sexual interest or resumed sexual activity earlier than OGB patients at 3 months postoperatively, hence demonstrating a faster recovery.

However, and although LGBP is considered as a minimally invasive procedure, most of the patients complain of abdominal pain after surgery [36-38]. Cho et al., [36], have reported that 98.94% of patients were found to have pain in the first 24 hours of post-surgery, 60% at the end of the first week and 29.5% still had pain four weeks after the surgery. The highest incidence of abdominal pain was in left upper quadrant. Moreover, 45% of patients were admitted to the emergency department complaining of abdominal pain. About 54.1% of these patients were referred again for the second time and 22.6% were admitted for the third time, all due to abdominal pain.

Eidy et al., [39], analyzed the distribution and frequency of post LGBP pain in 190 morbidly obese patients. The results of the study were similar to those published by Cho et al., Left upper quadrant was found to be the most prevalent site for pain, probably related to the insertion of drainage.

There are many reasons for pain after gastric bypass surgeries, several of which could be related to the behavioral eating patterns, such as rapid eating [40], food intolerance, like rice, vegetables, fruits, pasta, gluten and lactose intolerance, some deficiencies like folate and vitamin B12 deficiencies [41] and finally bacterial overgrowth [42]. Other etiologies could be constipation and lower abdominal pain due functional changes of the gastrointestinal tract after surgery, retrosternal pain, biliar colics because of de novo gallbladder stones, ulcers in gastric pouch, gastroesophageal reflux disease (GERD), anastomotic stenosis, trocar site hernia, adhesions band, incisional hernia, intussusceptions, omental torsion, infarction, internal hernia and bezoars.

Similar to other minimal invasive operations, the late pain following GB surgery is a serious problem. Chronic postsurgical pain (CPSP) has been defined as pain persisting for more than 3 months after expected healing time. CPSP of the surgical site after bariatric surgery has been reported in up to 50% of the patients.

Finally, Kumar et al., [4], performed a review of the literature in order to identify follow-up studies on pain and bariatric surgery. Sixteen studies were included for further analysis with over 2000 subjects (60% of them were on bypass surgery). “Short term” studies with data on pain within 3 months after surgery were randomized controlled trials comparing surgical techniques or analgesia. Although pre-operative pain status had not been documented, peri-operative pain management was reported in detail. In 8 observational studies, pain data were available exceeding 3 months after surgery (“long term” studies). While pre-operative pain data were reported in the latter studies, in over half the anatomic location of the pain had not been specified. Authors concluded that an accurate estimation of the incidence of CPSP after bariatric surgery was not possible based on the available data. The reason is that number of comparable studies was low and the anatomic location of the pain had not been specified. Moreover, data on pain between 1 week and 6 months after surgery (time point after measured pain is defined as chronic) were lacking.

To end up, the laparoscopic approach has shown to have special benefits to obese patients because of less blood loss, earlier mobilization, reduced postoperative pain, shorter hospital stay and faster convalescence in comparison with the open procedure. Nowadays, there is no discussion about whether laparoscopy should be the treatment of choice for bariatric patients. However, and although laparoscopic gastric bypass is considered as a minimally invasive procedure, many patients complain of abdominal pain after surgery, and chronic postsurgical pain has been reported in up to 50% of the patients. Despite the developments in pain management, postoperative pain is still a clinical problem.

PERITONEAL LAVAGE AND LAPAROSCOPIC SLEEVE GASTRECTOMY SURGERY

Lorea Zubiaga^{1,*}, MD, PhD and Jaime Ruiz-Tovar², MD, PhD

¹Inserm U1190, Lille 2 University, Lille, France

²Surgery Department, Autonoma University, Madrid, Spain

ABSTRACT

To prevent or remove bacterial proliferation after different abdominal surgeries, different solutions for peritoneal lavage have been proposed. This procedure is usually described on laparotomic surgery, but it is not current practice on laparoscopic procedures. Peritoneal lavage may reduce bacterial contamination, but does not completely eliminate them. The addition of antibiotic agents might further reduce the bacterial contamination. Despite surgical-site infection is a relatively rare complication after bariatric surgery, antibiotic lavage does not show its effect on this issue. However, the eventual reduction in the bacterial contamination reduces the inflammatory response and consequently diminishes the postoperative pain.

Keywords: peritoneal lavage, antibiotic solution, postoperative pain, acute-phase reactants, peritoneal contamination, surgical site infection

INTRODUCTION

Following laparotomy, abdominal surgery develops some degree of peritoneal contamination and surgical site infection (SSI) due to complex processes involving injured tissues and peritoneum. For most patients, peritoneal contamination and SSI have no clinical consequences due to the effectiveness of the patient's own immune response and prophylaxis with intravenous antibiotics, but SSI is associated with increased health care resource utilization and, in some cases, the peritoneal contamination is the prelude to infectious

* Corresponding Author's Email: loreazubiaga@gmail.com.

problems that go unnoticed until it is too late. [1] It is assumed that many of these processes of SSI have been significantly reduced by the shift from conventional laparotomy to laparoscopic surgery. [2]

Surgical site infection (SSI) is one of the most common complications of abdominal surgery. It is associated with longer hospital stays, lower quality of life and increased morbidity and mortality and sanitary cost. Centers for disease control (CDC) defines SSI as infection that occurs in or near the surgical incision during the first 30 days, or up to one year, if an implant has been left in place. [3] SSI occurs when the bacterial inoculum exceeds the ability of the immune system to control it. Contamination in abdominal surgery comes from the skin or target organs being treated. The abdominal organs are typically the gastrointestinal tract, a system that coexists with a significant number of microbes that under normal conditions are contained by the immune system, but in cases of surgical aggression can become highly virulent pathogens.

The determinants of infection are the surgeon, the pathogen and the patient. [3, 4] The surgeon is the main modulator of the surgical infection. Their experience and ability can reduce the inoculum to dimensions controllable by the body's defenses. A proper surgical procedure includes careful tissue management, good hemostasis, no unnecessary lengthening of surgical time and minimizing extravasation of gastrointestinal contents. Patients' dependent factors include comorbidities, obesity, smoking, and old age.

Many surgeons have adopted peritoneal lavage on different abdominal surgeries, mainly by laparotomy and/or peritonitis conditions. [5] This lavage usually consists of peritoneal irrigation with a variable volume of warm 0.9% sodium chloride physiologic solution (Saline Solution –SS-). The main mechanism of action of these lavages is to remove large accumulations of infectious material (feces, pus, necrotic tissue, etc.) and to dilute as much as possible the bacterial charge and other materials, that promote bacterial proliferation (e.g., blood) at the peritoneum. However, the effects of lavage have been widely studied, but with controversial results yet. [5-7] Peritoneal lavage can be altered by three basic variables: volume of irrigation fluid, timing of delivery and/or solution composition. Therefore, flushing the peritoneal cavity may also reduce the bacterial load and possibly minimize the risk of SSI. [8] Obviously, the efficacy of peritoneal irrigations in peritonitis is unclear. Moreover, the prophylactic effect of lavage in elective clean contaminated surgery is even less well understood than in peritonitis, because few relevant studies have been conducted.

Cases of undiagnosed serious abdominal infections are also common in obese patients undergoing bariatric surgery, as in many cases they are patients with a series of comorbidities (such as diabetes and dyslipemia) that aggravate the basal situation. [9] Gastric leak after sleeve gastrectomy is associated with significant and prolonged morbidity, remaining one of the most feared complications. Based on the data from International Sleeve Gastrectomy Expert Panel Consensus Statement 2011, the leak rate was near to 1.06%, but the leak rate can vary between 1% and 3% for primary procedure and more than 10% in revision techniques. [10] A gastric leak can present as peritonitis, abscesses, cutaneous or other fistulas, sepsis, organ failure and even death.

Furthermore performing a lavage with large amounts of SS is not a frequent procedure in laparoscopic bariatric surgery, since achieving the total and correct aspiration of all the infused serum is not easy in obese patients. The obese patients have an important amount of visceral adipose tissue, which makes any maneuver in the abdominal cavity even more difficult. Above all, it is precisely the visceral fat of obese patients that has a high capacity to

hide the bacterial niches and reproduce process of infection, which are difficult to diagnose and treat. For this reason, it has been proposed to use antibiotic solutions for the peritoneal lavage.

PERITONEAL LAVAGE WITH ANTIBIOTIC SOLUTIONS

Several antibiotics have been used for peritoneal lavage in diverse pathologies. The most widely investigated pathologies, in which antibiotic solutions were used was peritonitis. [8, 11] Up to our knowledge, our group was the first one to investigate the effect of peritoneal lavage with antibiotic solutions in bariatric surgery. We evaluated the effects of peritoneal lavage with physiologic saline solution (SS) or an antibiotic solution (AS) (clindamycin–gentamicin) on post-operative pain, acute-phase reactants and SSI. The microbiologic impact of both irrigations on peritoneal contamination was also determined.

A randomized study was performed with the following inclusion criteria were body mass index (BMI) either $>40\text{kg/m}^2$ or $>35\text{kg/m}^2$ with co-morbidities associated with obesity and undergoing laparoscopic sleeve gastrectomy (LSG) as a bariatric procedure. Exclusion criteria were documented uncontrolled psychiatric disorders, active infection or malignant disease, gastroesophageal reflux and other concomitant pathologies considered to be a contraindication to perform the LSG. A pre-operative diagnosis of chronic renal failure (because of the risk of nephrotoxicity associated with intraperitoneal gentamicin absorption) was also considered an exclusion criterion.

The surgical technique was performed as usual for LSG: A longitudinal resection from the angle of His to approximately 3 to 4 cm cranially to the pylorus was performed using a 40 French bougie inserted along the lesser curve. A staple line inversion was performed with a continuous over-sewing of polypropylene 3-0 before extracting the bougie. The remnant stomach was extracted through the 12-mm port site located in the right hypochondrium. The aponeurotic defect of only the 12-mm port site was closed using two simple sutures of polydioxanone (size 2) and the skin of all port sites with staples.

The lavage was performed with an irrigation-aspiration device immediately prior to closure of the port sites. In Group 1, irrigation of the entire abdominal cavity was performed with 500 mL of SS. In Group 2, lavage was carried out with the AS, including gentamicin (240 mg) and clindamycin (600mg) dissolved in 500mL of physiologic saline. In both groups, the solution was allowed to stand in the abdominal cavity for 3 min. Pre-operative systemic prophylaxis was performed in all the patients with cefazoline 3g intravenously and another dose of cefazoline.

Prior to any lavage, a microbiologic sample was obtained from the peritoneal surface (parietal and visceral from the gastric tube) with a swab introduced through the 12-mm port site (sample 1). After the assigned lavage and aspiration of the irrigation liquid, a new microbiologic sample was obtained from the peritoneum and the visceral surface of the gastric tube (sample 2). The drainage volume on the second day was collected in a syringe for microbiologic study (sample 3).

Table 1. Baseline features of the patients

	SS	AS	P
N	40	40	
Mean Age ($\pm$ SD)	41.6 $\pm$ 7.1	44.6 $\pm$ 7.4	0.541
BMI ($\pm$ SD)	46.9 $\pm$ 7.5	48.7 $\pm$ 7.6	0.732
Female/male ^{††} _{SEP}	30/10	32/8 ^{††} _{SEP}	0.689
Comorbidities (%)			
T2D	8 (20)	9 (22.5)	0.781
Hypertension	10 (25)	10 (25)	1
Dyslipidemia	7 (17.5)	8 (20) ^{††} _{SEP}	0.772
SAHS	6(15)	5 (12.5)	0.745

(SS: Saline Solution; AS: Antibiotic Solution; SD: Standard Deviation; BMI: Body Mass Index; T2D: Type 2 Diabetes; SAHS: sleep apnea/hypopnea syndrome).

The clinical variables investigated were age, gender, co-morbidities, complications (gastric leak, incisional SSI, and organ-space SSI), post-operative pain assessed 24 hours after surgery by the Visual Analog Scale for Pain (VAS) and morphine needs, occurrence of post-operative nausea or vomiting, analytical variables determined 24 hours after surgery (C-reactive protein [CRP]; white blood cell [WBC] count and lactic acid) compared to hospital stay. Microbiologic variables consisted of cultures of the three extracted samples.

Incisional SSI was defined as the presence of a purulent discharge from any of the surgical sites confirmed with culture. An epidemiology nurse blinded to the treatment groups determined incisional SSI. Infection surveillance was extended for 30 days after discharge. Organ-space SSI was defined as a fluid collection on a contrast-enhanced computed tomography (CT) scan in a patient presenting with fever, tachycardia, abdominal pain, or septic status. The evidence of oral contrast extravasation on a CT scan was considered a leak rather than an organ-space SSI. A radiologist blinded to the treatment group determined the diagnosis of organ-space SSI and leak in case there was one.

A total of 80 patients were included in the study, 40 in each group. The sample consisted of 62 females and 18 males with a mean age of 43 ± 7.2 years. Pre-operative BMI of $47.8 \text{ Kg/m}^2 \pm 7.7 \text{ Kg/m}^2$. The distribution of age, gender, BMI, and co-morbidities was similar in both groups (Table 1).

The post-operative complication rate was 3.7%, consisting of two leaks at the Hiss angle junction (one in each group), satisfactorily resolved with conservative treatment. In SS group one deceased occurred due to pulmonary embolism despite correct thromboembolic prophylaxis. There were no significant differences in the morbidity or mortality rates in the two groups. Given that the hospital stay, pain perception, and laboratory values of the three patients presenting with complications might be altered, as intra-abdominal infection can lead to elevation of all of them, these patients were excluded from the analysis of post-operative pain, laboratory values of acute-phase reactants, and microbiologic study.

The median post-operative pain score 24 hours after surgery was 3.5 (range 2–7) in Group SS and 1.5 (range 0–4) in Group AS ($p = 0.021$). Morphine administration was required in two patients in Group SS and 0 in Group AS ($p = 0.15$). Post-operative nausea or vomiting appeared in five patients (13%) in Group AS and 4 (10%) in Group SS ($p = 0.72$).

The laboratory data 24 hours after surgery are shown in the graphic below (Figure 1). The WBC count also was significantly higher in Group SS (mean difference 1,930/mm³; 95% CI

145–66,839; $p = 0.029$). The mean CRP concentration also was higher in Group SS (mean difference 27.3 mg/L; 95% CI 16.4–71.2; $p = 0.036$). Finally, the mean lactic acid concentration also was higher in Group SS (mean difference 0.34 mg/L; 95% CI 0.1–0.7; $p = 0.049$). The median hospital stay was 3.5 days (range 3–5 days) in Group SS and 2.5 days (range 2–4 days) in Group AS ($p = 0.05$).

The culture of sample 1 (before any lavage) was positive in seven cases (18.4%) in Group SS and eight cases (20.5%) in Group AS ($p = 0.77$). The culture of sample 2 (after lavage) was positive in 18.4% of the patients in Group SS and 0 in Group AS ($p = 0.006$). The culture of sample 3 (drainage discharge) was positive in three patients (7.9%) in Group SS and 0 in Group AS ($p = 0.08$). The microorganism detected was *Escherichia coli* in all cases. No significant association between microbiologic contamination and clinical or analytical variables could be demonstrated.

In case of peritonitis a peritoneal lavage is mandatory to obtain prompt and fast resolution of the severe infection. [6] In fact, the ideal peritoneal lavage solution should be effective, easy to apply and with low posterior complications or adhesions formation. Several studies tried to establish effective protocols of peritoneal lavage; some authors focused on the effect of temperature, the volume of solution or different methods, such as cyclic intraperitoneal lavage by bi-luminal drainages. Meanwhile, no method has been universally accepted yet. [12] Some authors showed that peritoneal lavage with saline, antibiotics, or antiseptics solution does not influence the outcome following laparotomies for peritonitis. Having so few conclusions in laparotomic surgery, it is evident that much less evidence exists in laparoscopic one. [1]

Figure 1. Laboratory data 24 hours after surgery.

The LSG is considered a clean-contaminated procedure, because the stomach is divided during this procedure. Thus, peri-operative systemic antibiotic prophylaxis is usually administered. In this sense, the SSI rate after laparoscopic surgery is significantly lower than that after conventional surgery, and this is especially relevant in morbidly obese subjects, as this condition itself is a risk factor for post-operative SSI. In this study, the highest contamination rate was 20% in both groups and the only micro-organism that grew in the cultures was *E. coli*. Thus, the peritoneal contamination in laparoscopically performed operations is much lower than conventional open surgeries and not only reduces the incisional SSI. [9] The abdominal wound is an important problem in obese patients, not only by the size of the skin-peritoneum damage, but also as the subcutaneous fatty tissue is easily colonized

by skin flora. It is evident that laparoscopy must be the elective approach for obese patients. In this way, the contamination of SSI is reduced to the intestinal saprophytic flora in the peritoneum and contamination of the subcutaneous tissue is avoided.

The concept of antibiotic irrigation is focused on reduction of SSI on wound. It seems to make no sense when performed in patients undergoing laparoscopic bariatric surgery with such a low contamination rate compared with colorectal surgery. [11] The fact that, SSI rates are not as high as in contaminated procedures reveals that host immunity can control contamination in most cases. The host as an aggression identifies the microorganism contamination, and it produces an inflammatory response. Surgical dissection indeed is an aggression sufficient to start an inflammatory response, but bacterial contamination might contribute to the increase and prolong it. [5]

Among several markers of inflammation, CRP has been studied widely to investigate its accuracy for the diagnosis of bacterial infection and the associated inflammatory response. [14, 15] The protein is an acute-phase reactant, synthesized by the liver, mainly in response to interleukin-6, which is produced not only during infection, but also in many types of inflammation, including the normal course after open or laparoscopic abdominal surgery. This fact justifies the higher concentrations of CRP observed in the post-operative course of most patients, even those having uncomplicated surgery. [14] Furthermore, CRP elevation is predictive of infective post-operative complications. In our series, the elevated CRP concentrations were markers of greater contamination. [16]

For fibrinogen, we could not find an effect like that reported for other acute-phase reactants. However, the accuracy of fibrinogen measurement for the diagnosis of inflammatory response secondary to bacterial infection or contamination seems to be lower, as reported by other authors. [17, 18]

Post-operative pain is a clinical reflection of tissue damage and the consequent inflammatory response. Local release of cytokines by the inflammatory cells stimulates nociceptive nervous receptors, and these trigger pain perception. Thus, a greater inflammatory response increases pain. After surgery the pain perception evaluated by VAS correlates directly with inflammatory cytokines concentrations. [19] In the present study, we could not demonstrate any association between pain, analytical values, and contamination. However, the reduction of all these parameters in the group of patients, who underwent antibiotic irrigation, indicates that the clinical relevance of these procedures beyond the improvement of acute-phase reactants is the reduction of post-operative pain. [20]

According to the results obtained, we believe that peritoneal lavage with antibiotic solution can be recommended in patients undergoing laparoscopic sleeve gastrectomy, and probably other bariatric procedures, but the latter hypothesis must be confirmed in similar studies conducted in other bariatric operations. Another limitation of this study is the small sample, which we used in order to obtain significant results on SSI reduction, one of the principal objectives of the study. More studies must be conducted with larger samples to confirm these hypotheses.

CONCLUSION

Intraperitoneal irrigation with a gentamicin and clindamycin solution in patients undergoing LSG leads to less alteration of acute-phase reactants, decrease postoperative pain and shorter hospital stay. Peritoneal lavage with antibiotic solutions can be considered an effective tool in the multimodal analgesia for bariatric surgery.

Chapter 455

PROPHYLAXIS OF DEEP-VEIN THROMBOSIS IN BARIATRIC SURGERY

Jaime Ruiz-Tovar*, MD, PhD and Carolina Llaveró

Obesity Unit, Garcilaso Clinic, Madrid, Spain

ABSTRACT

Obesity is associated with an increased risk of thromboembolic events. Venous thromboembolisms are the most common postoperative medical complications after bariatric surgery. Moreover, most bariatric procedures actually are performed by laparoscopic approach, implying an increased intraabdominal pressure during the surgical procedure that may favor the development of thrombus. The incidence of deep vein thrombosis (DVT) after laparoscopic bariatric surgery is about 3%. The prolonged anti-Trendelenburg position is considered the most important risk factor for venous thromboembolisms.

DVT is probably the most easily detected complication associated with venous thromboembolism, as it tends to appear with unilateral pain in the lower limb, associated with gastrocnemius edema and tenderness. DVT alone is not a life-threatening condition, but its main risk is migration of the thrombus and the development of pulmonary embolism (PE).

Therefore, bariatric surgery is considered a high-risk procedure for thromboembolic events. Actual recommendations are to include low molecular weight heparins (LMWH) and compression stockings in the primary prophylaxis of thromboembolic events.

INTRODUCTION

According to the World Health Organization (WHO), there are 1.6 billion overweight and 400 million obese people worldwide. Bariatric surgery has demonstrated to be the most effective and sustainable method for the regulation of morbid obesity, superior to both

* Corresponding Author's Email: jruiztovar@gmail.com.

pharmaceutical interventions and combinations of diet and lifestyle regimens. Therefore, the number of bariatric procedures performed, mainly in developed countries, is increasing every year [1, 2].

Obesity itself is associated with an increased risk of thromboembolic events. Moreover, most bariatric procedures are actually performed by a laparoscopic approach, implying an increased intraabdominal pressure during the surgical procedure that may favor the development of thrombus. Therefore, bariatric surgery is considered a high risk procedure for thromboembolic events [3, 4].

MORBID OBESITY AS RISK FACTOR

It has been determined that obesity is associated with a hypercoagulability status. Morbidly obese patients present increased fibrinogen levels that may reach twofold the normal value. It has been proved that venous circulation flow is slower in the infradiaphragmatic territory and especially in the lower limbs. Both facts, associated with disorders in several coagulation factors, favor the appearance of venous thrombosis, thrombophlebitis, and thromboembolic events, mainly pulmonary thromboembolisms (PE), which are the first cause of mortality in obese patients.

Venous stasis and hypercoagulability improve with weight loss, mostly after bariatric surgery. This improvement is achieved several months after the surgical procedure, when an important weight reduction has been obtained. More than 90% of patients undergoing any bariatric procedure present a relevant reduction of their hypercoagulability.

PE is also the most frequent cause of mortality in the immediate postoperative course of any kind of surgery in obese patients. Thus, they are considered as high-risk subjects, requiring intense prophylactic measures (mechanical and pharmacological) [5-7].

LAPAROSCOPIC BARIATRIC SURGERY

Venous thromboembolism is the most common postoperative medical complication after bariatric surgery. The incidence of deep vein thrombosis (DVT) after laparoscopic bariatric surgery is about 3% and that of pulmonary embolism (PE) is less than 1%. However, mortality associated with PE is estimated to be between 50% and 75% [8-10].

In laparoscopic abdominal surgery, the increase of intraabdominal pressure by the pneumoperitoneum, the prolonged operation time, and the anti-Trendelenburg position are considered risk factors for venous thromboembolisms. Moreover, hypercapnia induces vasoconstriction. It has been also demonstrated that surgical dissection induces the release of procoagulant cytokines. Other causes of venous thromboembolism after bariatric surgery is dehydration, especially after restrictive procedures, when patients hardly drink [11].

CLINICAL MANIFESTATIONS AND DIAGNOSIS

Venous thromboembolisms are often a challenging issue for the medical staff. DVT is probably the most easily detected complication associated with venous thromboembolism, as

it tends to appear with unilateral pain in the lower limb, associated with gastrocnemic edema and tenderness.

DVT alone is not a life-threatening condition, but its main risk is migration of the thrombus and the development of PE. The gold standard method for the diagnosis of DVT is Doppler ultrasonography (US).

PE usually appears with sudden unexplained dyspnea without any relevant features at the physical examination and on X-ray plain films. Laboratory data may show increased levels of D dimers, which present high sensitivity but low specificity for the suspicion of PE. The gold standard test for the diagnosis is a contrast-enhanced thoracic computed tomography (CT) scan showing a filling defect in the pulmonary arteries or their branches [11].

ANTITHROMBOEMBOLIC PROPHYLAXIS (PRIMARY PROPHYLAXIS)

Venous thromboembolisms are life-threatening conditions. Several measures, including prophylactic low molecular weight heparins (LMWH) and compressive stockings, are adopted to reduce their incidence. Up to the present there is no consensus about the optimal dosage of LMWH in the antithromboembolic prophylaxis for patients undergoing bariatric surgery. The dosage must be adjusted according to the weight of the patient, implying the need of administration of high preoperative doses.

Intra- and postoperative bleeding is one of the main complications of bariatric surgery. Many surgeons fear these complications and administer lower doses of LMWH than that recommended by most groups (Enoxaparin 0.5 mg/kg/day or Bemiparin 5000 UI/day or Dalteparin 50 UI/kg/day or Nadroparin 4100 UI/day) [12-15]. However, other authors report that this dose is insufficient because these patients are at high risk of developing thrombotic events [16-18].

The postoperative prolongation of prophylaxis is also a debated issue as some authors defend that a prolongation of 5-7 days is enough, whereas others report the need for maintaining it during 1 month, considering laparoscopic bariatric surgery as a high-risk procedure performed in high-risk patients [19-21]. In our opinion, a preoperative dose of 0.5 mg/kg/day administered 12 h before surgery and maintained postoperatively for 1 month is an adequate scheme for pharmacological antithromboembolic prophylaxis. We also fear intraoperative bleeding, but at these doses, it is not especially relevant in our experience. However, a postoperative thromboembolic event is a life-threatening condition for us that, once established, could be very difficult to manage.

Compression stockings must be maintained during the surgical event and postoperatively until the patient is able to make a proper ambulation [22, 23].

SCREENING FOR ASYMPTOMATIC VENOUS THROMBOEMBOLISM (SECONDARY PROPHYLAXIS)

As has already been mentioned, venous thromboembolisms are asymptomatic in many cases. In DVT it is especially important to achieve an early diagnosis to avoid the

development of life-threatening conditions, such as PE. With this aim, our group performed a prospective observational study of 100 consecutive patients undergoing laparoscopic sleeve gastrectomy as a bariatric procedure. DVT and porto-spleno-mesenteric vein thrombosis (PSMVT) were investigated 3 months after surgery with Doppler US and contrast-enhanced abdominal CT scan. The results of this study revealed that 2% presented unnoticed DVT and 1% unnoticed PSMVT. All these patients were asymptomatic. According to these results, we concluded that a routine postoperative screening with Doppler US or contrast-enhanced CT seems to be unnecessary [24].

São Paulo, Brazil

INTRODUCTION

The congenital cardiovascular anesthesiologist's central role is to design an anesthetic strategy for a patient who often has limited cardiovascular reserve and constitutes a key component for optimal perioperative care of these complex patients.

PREOPERATIVE CONSIDERATIONS

It's mandatory to understand the type of congenital heart disease and evaluate the patient's functional status (Table 1), since it reveals their cardiopulmonary reserve [1, 2].

RISK STRATIFICATION

There are a few risk stratification tools available to access the risk of postoperative death in children undergoing cardiac surgery. They are: Risk Adjustment for Congenital Heart Surgery (RACHS-1) score (Table 2), the Basic Aristotle Complexity Score, and the Society of Thoracic Surgeons and the European Association for Cardiothoracic Surgery Mortality score (STS-EACTS score) (Table 3) [3-6].

According to Pacheco JT et al. [7], our CICU showed a 23.3% mortality in patients RACHS-1 category 6 in a 4-year analysis.

* Corresponding Author's Email: julianatpacheco@gmail.com.

Table 1. General preoperative care

Informed consent	Involves patient's and parent's knowledge of the upcoming intervention, reducing their anxiety and improving their involvement with postoperative care.
History and physical examination	Gestational age at birth. Previous surgery and hospital staying Anesthetic experiences and complications Diagnostic and therapeutic interventions Non-cardiac problems and syndromes Current medications Food allergies Evaluation of vital signs, cardiac rhythm, and pre- and post-ductal oxygen saturations, if there is any unrepaired defect.
Preoperative exams	Imaging studies and cardiac catheterization, and electrocardiographic evaluation are required in most interventions. Laboratory tests are based on the extent of surgery/procedure, signs and symptoms.
Fasting	Follows ASA (American Society of Anesthesiologists) guidelines.

Table 2. Procedures according to RACHS-1 category*Risk Category 1*

1. Partially anomalous pulmonary venous connection surgery
2. Coarctation repair at age >30 d
3. Patent ductus arteriosus surgery at age >30 d
4. Atrial septal defect surgery (including ostium secundum, sinus venosus, and PFO closure)

*Aortopexy**Risk Category 2*

1. Left ventricular to right atrial shunt repair
2. Common atrium closure
3. Transection of pulmonary artery
4. Repair of pulmonary artery stenosis and Pulmonary outflow tract augmentation
5. Coarctation repair at age ≤30 d
6. Repair of aorta-pulmonary window
7. Vascular ring surgery
8. Glenn procedure
9. Total repair of tetralogy of Fallot
10. Repair of total anomalous pulmonary veins at age >30 d
11. Repair of unspecified septal defect
12. Ventricular septal defect repair (with or without pulmonary artery banding removal or pulmonary valvotomy or infundibular resection)
13. Ostium primum atrial septal defect repair
14. Atrial septal defect and ventricular septal defect repair
15. Repair of coronary artery fistula
16. Right ventricular infundibulectomy
17. Pulmonary valve replacement, valvotomy or valvuloplasty
18. Aortic valvotomy or valvuloplasty at age >30 d
19. Subaortic stenosis resection

Risk Category 3

1. Repair of anomalous coronary artery with intrapulmonary tunnel
2. Closure of semilunar valve, aortic or pulmonary
3. RV or LV to pulmonary artery conduit
4. Repair of double-outlet right ventricle with or without repair of right ventricular obstruction
5. Fontan procedure
6. Repair of transitional or complete atrioventricular canal with or without valve replacement
7. Pulmonary artery banding
8. Repair of tetralogy of Fallot with pulmonary atresia
9. Repair of cor triatriatum
10. Systemic to pulmonary artery shunt
11. Atrial or arterial switch operation
12. Reimplantation of anomalous pulmonary artery
13. Annuloplasty Repair of coarctation and ventricular septal defect closure
14. Excision of intracardiac tumor
15. Repair of anomalous coronary artery without intrapulmonary tunnel
16. Tricuspid valve repositioning for Ebstein anomaly at age >30 d
17. Tricuspid valve replacement, valvotomy or valvuloplasty
18. Valvectomy of tricuspid valve
19. Mitral valve replacement, valvotomy or valvuloplasty
20. Aortoplasty
21. Ventriculomyotomy
22. Left ventricular outflow tract patch
23. Ross procedure
24. Aortic valve replacement

Risk Category 4

1. Aortic valvotomy or valvuloplasty at age ≤ 30 d
2. Konno procedure
3. Repair of complex anomaly (single ventricle) by ventricular septal defect enlargement
4. Repair of total anomalous pulmonary veins at age ≤ 30 d
5. Atrial septectomy repair of transposition, ventricular septal defect, and subpulmonary stenosis
6. Atrial switch operation with ventricular septal defect closure
7. Atrial switch operation with repair of subpulmonary stenosis
8. Arterial switch operation with pulmonary artery band removal
9. Arterial switch operation with ventricular septal defect closure
10. Arterial switch operation with repair of subpulmonary stenosis
11. Repair of truncus arteriosus
12. Repair of hypoplastic or interrupted arch without ventricular septal defect closure
13. Repair of hypoplastic or interrupted aortic arch with ventricular septal defect closure
14. Transverse arch graft
15. Unifocalization for tetralogy of Fallot and pulmonary atresia
16. Double switch

Risk Category 5

1. Tricuspid valve repositioning for neonatal Ebstein anomaly at age ≤ 30 d
2. Repair of truncus arteriosus
3. Repair of interrupted arch

Risk Category 6

1. Stage 1 repair of hypoplastic left heart syndrome (Norwood operation)
Damus-Kaye-Stansel procedure

Table 3. Procedures according to STAT score*Risk Category 1*

1. ASD repair (primary closure or patch repair)
2. Partial and Intermediate (transitional) AVSD repair
3. PAPCV repair
4. Aortic stenosis, subvalvar repair
5. ICD (AICD) implantation
6. Double chamber right ventricle repair
7. VSD repair (primary closure or patch repair)
8. Vascular ring repair
9. Coarctation repair (end to end anastomosis or interposition graft)
10. Aortic valve replacement (bioprosthetic or mechanical)
11. Pulmonary valve replacement
12. Conduit reoperation
13. TOF repair (no ventriculotomy and no transannular patch)
14. Fontan (lateral tunnel, fenestrated)
15. Aneurysm of sinus of Valsalva repair

Risk Category 2

1. PDA closure
2. LV to aorta tunnel repair
3. Tricuspid, mitral, aortic or pulmonary valvuloplasty
4. Tricuspid valve replacement
5. Truncal valve replacement
6. 1½ Ventricular repair
7. Arrhythmia surgery - surgical ablation
8. Permanent pacemaker implantation
9. Ross procedure
10. Aortopexy
11. Bidirectional Glenn procedure
12. Pulmonary artery reconstruction (plasty)
13. Fontan connection (external conduit, atriopulmonary connection and nonfenestrated lateral tunnel)
14. Atrial fenestration closure
15. Aortic root replacement (valve sparing or mechanical prothesis)
16. Conduit placement (including LV to PA)
17. Extended coarctation repair (end to end anastomosis or subclavian flap)
18. Anomalous origin of coronary artery repair
19. RVOT procedure
20. Aortic aneurysm repair
21. Congenitally corrected TGA repair
22. AP window repair
23. TOF repair (with ventriculotomy and transannular patch)
24. Aortic root replacement (bioprosthetic)
25. Supravalvar aortic stenosis repair
26. Pericardiectomy
27. LV aneurysm repair
28. Pulmonary artery origin from ascending aorta (hemitruncus) repair

29. Atrioseptectomy
30. PAPVC (scimitar) repair
31. Ligation of pulmonary artery
32. Coronary artery fistula ligation
33. Mitral stenosis and supraaortic mitral ring repair
34. Systemic venous stenosis repair
35. Cor triatriatum repair
36. Multiple VSD repair
37. Atrial baffle procedure (non-Mustard, non-Senning)
38. Partial left ventriculectomy (LV volume reduction surgery - Batista)
39. TOF repair with RV-PA conduit

Risk Category 3

1. Lung transplantation
2. Occlusion MAPCA(s)
3. Coarctation repair + VSD repair
4. Konno procedure
5. Coarctation repair with patch aortoplasty
6. PA, reconstruction (plasty), branch, central (within the hilar bifurcation)
7. Pulmonary artery or RV aneurysm repair
8. Ventricular septal fenestration
9. Shunt ligation and takedown
10. Hemi-Fontan procedure
11. Total AVSD repair
12. Anomalous systemic venous connection repair
13. ASO or Mustard procedure
14. Truncal valve valvuloplasty
15. Pulmonary embolectomy
16. ASD partial closure
17. Rastelli operation
18. Conduit placement (ventricle to aorta and RV to PA)
19. Aortic valve replacement (homograft)
20. REV
21. Pulmonary artery sling repair
22. Pulmonary atresia-VSD (including TOF, PA repair)

Risk Category 4

1. Mitral valve replacement
2. Pericardial drainage procedure
3. Aortic arch repair
4. Fontan revision or conversion (redo Fontan procedure)
5. DOLV and DORV (intraventricular tunnel) repair
6. ASO + aortic arch repair
7. PA debanding
8. ASO and VSD repair
9. Cardiac tumor resection
10. Heart transplantation
11. Coronary artery bypass
12. TOF-absent pulmonary valve repair

Table 3. (Continued)

13. Tricuspid valve excision (without replacement)
14. Modified BT Shunt or central shunt
15. AVSD + TOF repair
16. Ross-Konno procedure
17. Senning procedure
18. Ebstein's repair
19. Aortic arch repair + VSD repair
20. PA banding
21. Aortic root replacement with homograft
22. Unifocalization MAPCA(s)
23. Aortic dissection repair
24. Congenitally corrected TGA repair (VSD closure and LV to PA conduit)
25. Pulmonary atresia + VSD + MAPCA repair
26. ASD or VSD creation/enlargement
27. HLHS biventricular repair
28. TAPVC repair
29. Pulmonary venous stenosis repair
30. Interrupted aortic arch repair
31. Arterial switch procedure and VSD repair + aortic arch repair
32. Truncus arteriosus repair
33. Atrial septal fenestration
34. Tricuspid valve closure (exclusion, univentricular approach)
<i>Risk Category 5</i>
1. Damus-Kaye-Stansel procedure (creation of AP anastomosis without arch reconstruction)
2. Heart and lung transplantation
3. Congenitally corrected TGA repair (atrial switch + Rastelli operation or Double switch)
4. Norwood procedure
Truncus + IAA repair

ANESTHETIC AGENTS

The adequate choice of the anesthetic agent aims to preserve patients' hemodynamics. The most commonly used drugs are [8, 9, 10]:

- Opioids and benzodiazepines: the tendency to early extubation favors lower opioid doses (10-20 µg/kg of Fentanyl or equivalent). High doses (50-75 µg/kg) might be used in selected cases. Midazolam provides sedation and amnesia with hemodynamic stability.
- Volatile agents: Isoflurane, sevoflurane and desflurane at end-tidal. All volatile agents may depress myocardial contractility and cardiac output at high doses and should be used with caution.

- Ketamine: administration can be intravenous (IV) or intramuscular (IM). Induction dose of 1-2 mg/kg IV or 5-10 mg/kg IM, and maintenance dose of 1-5 mg/kg/hour are indicated.
- Dexmedetomidine: loading dose of 0.5-1 µg/kg given over 10 minutes, followed by a maintenance of 0.2-0.7 µg/kg/hour is commonly used as a coadjuvant.
- Propofol: caution must be taken with prolonged infusion and it should be indicated only in patients with adequate cardiovascular reserve.
- Etomidate: reserved to few patients with very limited cardiac reserve.

PERIOPERATIVE CONSIDERATIONS

PREMEDICATION

- Premedication is the first step to relax the patient, facilitate separation from parents, and enhance their composure having their child calm before the procedure. Numerous sedative-hypnotics may be used.
- Midazolam is commonly administered by different routes (intranasally 0.3mg/kg, orally 0.5–1mg/kg, IV 0.05 - 0,1 mg/kg). The oral route is well tolerated and easily administered.
- Intranasal dexmedetomidine (0.5–1 µg/kg) has also been used. The onset of action is delayed at 45 minutes.
- Ventilation and oxygenation should be monitored.

ANTIBIOTIC PROPHYLAXIS

- All cardiac surgery should receive antibiotic prophylaxis 30 to 60 minutes before surgical incision (see Chapter 16).
- Cefuroxime 50mg/kg q8h in case of hospital stay up to 7 days.
- Associate Vancomycin 15mg/kg q6h in case of hospital admission longer than one week.
- Antibiotics should be administered for 24 hours after surgery, except in case of open chest, when they should be discontinued only 24h after closed chest.

INDUCTION AND MAINTENANCE

- A superficial vein at any site is cannulated before induction or during inhalation induction of anesthesia.
- Induction can be achieved by inhalation of a volatile anaesthetic agent.
- Secure airway, arterial line and central venous access are obtained. Multi-lumen catheters are recommended.
- Some access sites (superior vena cava) in small infants with single-ventricular pathologies might be preserved.
- Patients receiving inotropes and vasodilators have the potential to significantly deteriorate with anesthetic exposure.
- Pulmonary hypertension increases the perioperative risk in patients with congenital heart disease. [11]

MONITORING

- Heart and respiratory rate, arterial line, CVP, pulse oximetry, continuous EKG, capnography, urine output, central temperature, cerebral and somatic oximetry, BIS, and left atrium and pulmonary pressure pressure if necessary.
- Coagulation point-of-care testing, activated clotting time (ACT), blood gas analysis, lactate, venous oxygen saturation, electrolytes, red blood cell count, and glycemia should be monitored during the surgery.

CORTICOSTEROIDS

- Limits the inflammatory response after bypass and may reduce the need for inotropes.
- Methylprednisolone is the drug of choice, 30mg/kg prior to CPB and at the start of CPB.

ANTIFIBRINOLYTIC THERAPY

- Both ϵ -aminocaproic acid and tranexamic acid appear effective in reducing bleeding and transfusion in cyanotic patients. [12]
- Dose: 50-100mg/kg/dose IV

HEPARIN

- Heparin injection precedes the cannulation of the great vessels.
- 300–400 units/kg is injected to reach a target ACT > 480 seconds prior to the initiation of CPB.
- Additional heparin doses: 200–400 units/kg in the circuit, and 50–100 units/kg ongoing administration every 30–120 minutes.

CPB

- After CPB is initiated, mechanical ventilation is discontinued. Anesthetic drugs can be added to the bypass circuit to maintain general anesthesia during CPB. Anticoagulation, fluid balance, organ perfusion, core temperature and cardioprotection are of particular importance.
- Use of the pH-stat strategy in infants undergoing deep hypothermic cardiopulmonary bypass is associated with lower postoperative morbidity, improved oxygen delivery, reduced ventilator dependence, and reduced ICU stays when compared to Alpha-stat. [13,14]
- During rewarming, inotropes might be initiated (milrinone and epinephrine are the preferred drugs for prevention and treatment of LCOS). Normal temperature is reached, heart is filled, ventilation is resumed, vasoactive drugs are titulated, and possible cardiac arrhythmias are treated before separation from bypass is initiated. [15]

POST CPB

- Modified ultrafiltration after CPB is commonly employed to decrease blood transfusion requirement, reduce cytokines, decrease tissue edema, improve myocardial perfusion, and reduce pulmonary vascular resistance.
- Surgical repair is assessed by transesophageal echocardiogram (TEE).
- Pulmonary hypertension, if present, must be treated.
- Heparin reversal is achieved with protamine and other coagulation disturbances are treated.
- Some patients fail to wean off CPB, despite an asserted surgical technique and all resources used, and ECMO is eligible.

POSTOPERATIVE CONSIDERATIONS

- The main goal when treating children who have undergone surgery for congenital heart disease is maintaining adequate tissue oxygenation, which is accomplished by maintaining systemic oxygen delivery and minimizing oxygen consumption [1, 16].

- To optimize oxygen delivery, improve sedation and analgesia, treat hyperthermia, it's advisable to consider muscle relaxation in critically ill patients under mechanical ventilation and blood transfusions [15].
- Increased oxygen consumption usually occurs in systemic inflammatory response and low cardiac output syndrome, bleeding, ischemia–reperfusion injury, postoperative myocardial dysfunction, right ventricular failure due to acute pulmonary hypertension, and decreased coronary perfusion [17].
- Postoperative management should consider limitations of the cardiovascular reserve in neonates, hematocrits targets and cardiovascular physiology after surgery.
- If coagulation, electrolytes, temperature and hemodynamics are normalized, and individual factors are considered, extubation may be performed in the operating room or programmed for the first hours after surgery [3].
- Early extubation and spontaneous ventilation are particularly desirable in patients undergoing bidirectional Glenn anastomosis, Fontan operations and Tetralogy of Fallot repair [17].
- Fast-track protocols also includes early extubation. For fast-tracking, prior to a balanced anesthetic technique, limit opioid use and prefer non-opioid analgesics or opioid-sparing drugs such as dexmedetomidine, in a multimodal pain management strategy. Typical benefits include less sedation, lower inotropic support, fewer mechanical ventilation-associated complications, more rapid patient mobilization, reduced parental stress, decreased length of ICU and hospital stay, and possibly cost savings [18].
- The transport from the OR to CICU must follow a systematic approach. Before leaving, remember to check before leaving the OR the drugs pump, the thresholds of the pacemaker, the airway equipment, the transport monitor, and to organize the lines.
- After arriving in the CICU, the anesthesiologist should report the patient's information and the operative course (anesthetic problems, ETT size and position, line locations, size and any problems, times of CPB, XC and DHCA, weaning from CPB and any issues, echo findings post-CPB, pacemaker settings, inotrope infusions, blood products given and last antibiotic time).

Barcelona, Spain

²Cardiac Intensive Care Unit, Children's Hospital of Pittsburgh,
Pittsburgh, US

INTRODUCTION

Cardiac arrhythmias are one of the most frequent postoperative complications after congenital heart surgery. Its incidences are estimated between 10-50% with a mortality that can reach up to 12%. The recognition and treatment of arrhythmias during the postoperative period is key after congenital heart surgery. Abnormal high and low heart rate arrhythmias (tachyarrhythmia and bradyarrhythmia, respectively) and the loss of atrioventricular synchrony are characteristic of some rhythms that can compromise cardiac output and therefore complicate the postoperative care of children with congenital heart disease.

BRADYARRHYTHMIAS

The most frequent bradyarrhythmias after cardiac surgery are:

- Sinus node dysfunction, usually transitory.
- Pharmacological bradyarrhythmia.
- AV block with its distinctive degrees.

* Corresponding Author's Email: SanchezDeToledoJ@upmc.edu.

1. Sinus node dysfunction:

It is caused by a dysfunction of the pacemaking mechanism within the sinus node, resulting in low heart rhythm with prolonged pauses or with a nodal escape rhythm.

Usually this appears after surgical manipulation of the right atrium. In most cases it is a temporal rhythm, but in some cases it can become a permanent rhythm.

2. Atrioventricular block (AVB):

AV block presents an alteration of the normal electrical conduction paths through the AV node. It can be present during or after surgeries affecting the left ventricular outflow track, interventricular septum and especially after Tetralogy of Fallot repair.

Classification:

- 2.1. *First degree:* P-R interval is enlarged but all the P waves are conductive and go through the AV node. Nonetheless, there is a delay in the electrical conduction. Does not produce important clinical alterations and does not require urgent treatment.
- 2.2. *Second degree:* Mobitz 1: (Wenkebach): Characterized by progressive enlargement of PR interval until a P wave does not depolarize the ventricle. Hemodynamically is usually well tolerated. Mobitz 2: Represents a progressive dysfunction of the AV node. An intermittent AV block develops and there is risk it will develop into a complete AV block.
- 2.3. *Third degree or complete AV block:* There is a loss of AV conduction. None of the P waves are producing a ventricle depolarization. A state of atrioventricular asynchrony is present. The ventricular escape rate rhythm will define the hemodynamic status of the patient.

Table 1. Drugs for bradyarrhythmia and their doses

Drugs	Indications	Doses	Secondary effects
Atropine	Sinus bradycardia AV block	Bolus: 0.01-0.02 mg/kg (min 0.1 mg, max 2 mg)	Tachycardia Paradoxical bradycardia
Epinephrine	Asystole (CPR) Extreme bradycardia	Bolus: 0.01 mg/kg Continuous infusion: 0.05-2 mcg/kg/min	Tachycardia Arterial hypertension Arrhythmias
Isoproterenol	AV block	Continuous infusion: 0.01-0.05 mcg/kg/min	Tachycardia Arrhythmias

The postoperative management is based on the utilization of sequential pacemaker, and for this reason temporary pace wires should be placed during the surgical procedure. The current recommendations are to place atrioventricular wires to secure adequate heart rate and AV synchrony. In case the AV wires are dysfunctional, chronotropic medications such as Isoproterenol, Atropine and Epinephrine could be used while pacemaker wires are restored to functional capacity or as new probes are placed (endocavitary or external).

Permanent pacemaker is indicated when a second-degree AV block (Mobitz 2) or complete AV block are present for more than 2 weeks.

TACHYARRHYTHMIAS

Tachyarrhythmias are the most common arrhythmias during the post-operative course. Etiology is usually multifactorial, including intra- and perioperative factors. In the last three decades, the therapeutical advances in this field have been few, and today the therapeutical options are limited. A practical way to classify these types of arrhythmias is to describe their etiopathology and location.

1. Etiopathology classification (Figure 1):

- 1.1. Reentrant tachyarrhythmias

- 1.2. Automatic tachyarrhythmias.

Classifying these arrhythmias into automatic and reentrant has a special interest from a clinical point of view and defines its therapeutic approach in the intensive care unit. *Reentrant tachyarrhythmias* are frequent in the neonatal period and less frequent during the immediate post-operative time. This class of arrhythmias appears suddenly and end in the same way, a phenomenon called “on-off.” Heart rates are fixed, and they usually respond to pharmacological and electrical cardioversion. On the other hand, *automatic tachyarrhythmias* are the most prevalent arrhythmias in the post-operative period. They usually appear in a progressive manner (“warm-up”) and dissipates slowly overtime (“cool down”). These types of arrhythmias are refractory to pharmacological treatment and characteristically also to electrical cardioversion.

2. Classification based on location (Figure 2):

- 2.1. Atrial arrhythmias

- 2.2. Conduction arrhythmias

- 2.3. Ventricular Arrhythmias.

The mechanism of action and location are important concepts that lead to a rapid diagnosis. For this reason, P/QRS ratio (Figure 2) is being used to identify the location of the arrhythmia and the proper differential diagnosis in most of the cases (Figure 3).

It is important to be aware of the most common associations between arrhythmias and surgical procedures (Table 2).

REENTRANT	
  Sudden start Constant heart rate Neonatal period Treatment: Electrical cardioversion, auricular over-stimulation or pharmacological cardioversion are effective (especially if the AV node is part of the reentrant circuit)	Types: -Atrial flutter -AV Macroreentrant Tachycardia -Intranodal AV (microreentrant) Tachycardia -Permanent AV junction reciprocal tachycardia
AUTOMATIC	
  Onset: "Warm-up/Cool-down". Variable heart rate. More frequent in post-operative period. <u>Treatment:</u> Hypothermia aiming to diminish automatism, optimization of sedation and pain management. Decrease inotrope support and normalization of electrolytes.	Types: -Atrial ectopic tachycardia -Multifocal Atrial Tachycardia -Junctional Ectopic Tachycardia (JET)

Figure 1. Tachyarrhythmias classification based on etiopathology (*Mechanism of Action*).

ATRIUM			
P / QRS ratio >1:1 (except for Atrial Flutter >1:1 or 1:1)	Atrial Ectopic Tachycardia (AET)		Treatment 1. Diminish automatism 2. Procainamide or Amiodarone 3. Beta blockers (Esmolol or propranolol) +/- flecainide or propafenone
	  Automatic	P Waves are no sinus P waves located before QRS Narrow QRS Small QRS Variable heart rate	
	Multifocal Atrial Tachycardia (MAT)		Treatment 1. Electrical cardioversion: 1J/Kg 2. Atrial over-stimulation 3. Amiodarone or procainamide. Other: Flecainide, digoxin
	  Automatic	Irregular P waves are morphologically irregular Clusters of short tachycardia	
	Atrial Flutter (AF)		Treatment 1. Electrical cardioversion: 1J/Kg 2. Atrial over-stimulation 3. Amiodarone or procainamide. Other: Flecainide, digoxin
	  Reentrant	Atrial pace >300 BPM P waves called "sawtooth" AV variable conduction 1:1-3:1 Narrow and irregular QRS Adenosine administration usually helps to show hidden AF	

Figure 2. (Continued).

CONDUCTION SYSTEM			
P / QRS ratio 1:1 (Except JET 1:1 or <1:1)	Orthodromic Atrioventricular reentrant tachycardia (AVRT)		Treatment
			Present of hidden accessory path P waves are retrograde to QRS Short QRS-P interval (0.08) Narrow QRS
	Reentrant		If patient is stable: 1. Vagal maneuvers and oxygen supplement. 2. IV adenosine bolus: 100 mcg/kg, >200 mcg/kg, >300mcg/kg 3. Amiodarone or procainamide. Other: Flecainide or Esmolol. 4. Atrial overstimulation.
	Antidromic Atrioventricular reentrant Tachycardia (AVRT)		Unstable:
			1. Electrical synchronized cardioversion 1J/kg-2J/kg 2. Follow same algorithm of pharmacological treatment * In a hyperadrenergic state, patients usually go back into the arrhythmia after adenosine
	Reentrant	Wolf Parkinson White Accessory Path Delta wave on sinus rhythm P retrograde wave on DII and AVF Short QRS-P interval (0.08) Wide QRS	challenge, in those cases long acting meds are needed Digoxin, beta-blockers, amiodarone, procainamide * If PJRT comes back after cardioversion amiodarone treatment is recommended. Early ablation is recommended in such cases.
	Intranodal Atrioventricular reentrant tachycardia (AVNRT)		
			No visible P wave, QRS-P ratio very short. And P wave superimposed by QRS complex. Simultaneous depolarization of Atrium and ventricles. Double nodal pathway: Fast and slow
	Reentrant		
	Permanent junctional reciprocating tachycardia (PJRT)		
			Incessant heart rate of 200 BPM. DII, DIII and AVF P wave inverted preceding a QRS complex Long QRS-P interval
	Reentrant		
	Junctional Ectopic Tachycardia (JET)		Treatment
			Rate: >170 BPM AV dissociation Narrow QRS Retrograde P waves
	Automatic		1. Diminish automatism 2. Hypothermia 34-36C 3. Amiodarone 4. If amiodarone is not enough, procainamide (aiming to decrease nodal rhythm) is recommended. 5. AV resynchronization with pacemaker 6. Dexmedetomidine. *** 7. Corticosteroids. ***

VENTRICULAR			
P / QRS ratio <1:1	Ventricular tachycardia (VT)		Treatment
			Wide QRS complex P waves do not precede QRS Capture ventricular beats Last > 30 secs
			1. <u>Unstable</u> : Electrical synchronized cardioversion. 1 J/kg <u>Stable</u> : Amiodarone 2. Lidocaine 3. Procainamide *Torsade de pointes: IV magnesium sulfate 15-30mg/kg over 20 minutes
	Ventricular Fibrillation (VF)		Treatment
			Irregular and chaotic rhythm Hemodynamic shock
			Cardiopulmonary reanimation (CPR) 1. Defibrillation: 4J/Kg 2. Epinephrine: 0.01mg/kg IV After 3 to 5 defibrillation attempts Amiodarone IV 5mg/kg + Epinephrine IV 0.01 mg/kg

Figure 2. Tachyarrhythmias classification based on location.

QRS Amplitude: Narrow: <80 ms; Wide: >80 ms.; EAT: Ectopic Atrial Tachycardia.; MAT: Multifocal Atrial Tachycardia.; AF: Atrial fibrillation; AVNRT: Atrioventricular Nodal Reentrant Tachycardia; AVRT: Atrioventricular Reentrant Tachycardia; PJRT: Permanent Junctional Reciprocating Tachycardia; VT: Ventricular Tachycardia; SVT: Supraventricular Tachycardia; RBBB: Right Bundle Branch Block

Figure 3. Tachyarrhythmias differential diagnosis.

Table 2. Congenital heart surgery and respectively associated arrhythmias

Surgery/Diagnosis	Common arrhythmias
Ebstein Anomaly	Atrial arrhythmias Ventricular arrhythmias
Pulmonary Atresia (single ventricle)	Atrial arrhythmias
Atrioventricular septal defects	AV block JET
Atrial Septal defect	AV node dysfunction Atrial Reentrant Tachycardia RBBB JET
Ventricular septal defect	RBBB AV block JET
Double outlet right ventricle	AV block Ventricular tachycardia
Aortic Stenosis	AV Block
Fontan	Sinus node dysfunction Atrial Reentrant Tachycardia
Heterotaxy	Complete AV block
Norwood	JET
LVOT repair	LBbB
Total anomalous pulmonary venous connection	Sinus node dysfunction Atrial arrhythmias JET
Senning/Mustard	Atrial reentrant tachycardia
Tetralogy of Fallot	RBBB JET Ventricular tachycardia
Transposition of the great arteries	Sinus node dysfunction Atrial arrhythmias Complete AV block Ventricular tachycardia
Truncus Arteriosus	AV block JET Ventricular Tachycardia

JUNCTIONAL ECTOPIC TACHYCARDIA

Junctional ectopic tachycardia (JET) is the most common arrhythmia with hemodynamic consequences in the postoperative period. It usually appears with the first 24 to 48 hours, it is intermittent, and it could last between 2-5 days. It has an incident variation between 10-50%, with an important associated morbidity and mortality up to 13.5%.

Definition

Defined as an automatic tachyarrhythmia with origin in the AV node, it is considered a narrow QRS arrhythmia with a heart rate of >170 PBM plus an AV dissociation. Occasionally P retrogrades waves can be seen in an auriculogram (Figure 4).

Figure 4. Diagnostic Auriculogram for a JET.

Risk Factors

- Predominant in neonates and infants
- Highly complex surgeries with prolonged surgical times, including CPB >100 minutes
- Myocardial ischemia: Post-operative patients with high inotropic support (>2 inotropes meds), hyperlactatemia (>20 mg/dl)
- Other factors: Hyperthermia, Hypomagnesemia.

TGA repair, AVSD repair and TOF repair are the most common surgical procedures associated with JET.

Traumatism of the AV node and/or the His system has been postulated as the main cause of JET, however the real mechanism is unknown. The endogenous or exogenous adrenergic release is extremely important in the physiopathology mechanism and the increase of automatism.

The modulation of the sympathetic system and inflammatory process are of benefit in the post-operative period, to ensure restoration of normal organic function. The combination of AV asynchronicity and elevated heart rates leads to a poor cardiac output and haemodynamic instability.

Treatment

A more physiological heart rate is the main goal of the treatment. If cardiac output is compromised, reestablishing AV synchrony with pacemaker is a priority.

Therefore, it is advised to:

1. Use strategies to diminish the endogenous and exogenous catecholamine release, including:
 - a) Sedation and analgesia optimization
 - b) Reduction of any exogenous catecholaminergic support.
 - c) Keeping electrolytes within the normal range is advised (Mg and Ca). Magnesium supplementation during CPB has been associated with less postoperative JET.
 - d) Avoiding hyperthermia and keeping a relatively low temperature (35-36°C)
 - e) Corticosteroids have been suggested as a treatment, however there is not enough evidence to recommend them.
 - f) Decreasing the nodal rhythm with antiarrhythmics. Amiodarone is the recommended medication. Procainamide could be contemplated.
 - g) Using dexmedetomidine as a coadjutant in the management of sedation during the post-operative period. This agent has also been associated with a preventive medication for post-operative JET.
2. Pace sequentially to restore AV synchrony.

The main goal is to reestablish AV synchrony. In the majority of the cases when the nodal frequency has diminished to <150, atrial stimulation (AAI or AOO) is enough to restore AV synchrony. If this situation does not happen, it is necessary to use a pacemaker on a sequential modality (DDD).

ARRHYTHMIA TREATMENT

Post-operative arrhythmia management is based on a combination of pharmacological therapy and sequential pacemaker.

The pharmacological treatment is wide. Vaughan Williams' antiarrhythmic drugs classification (Table 3) is the most used one and it is based on the drug's mechanism of action. This classification is incomplete since it does not include alpha adrenergic blockers, cholinergic agonist and ionic supplements. In 1991, the European Cardiology Society proposed a new classification, however, Vaughan Williams' is still the most used classification.

Table 3. Vaughan-Williams' drugs antiarrhythmics classification

Class	Mechanism of action and effects	Indications	Anti arrhythmic	Dose	Adverse effects	
I	A	NA channel blocker (phase 0) Decreased Heart Rate Increased action potential duration Increased QT Moderate decrease in conduction AV block	SVT Ventricular arrhythmias Pre-excitation syndrome JET Atrial fibrillation	Procainamide <i>Others</i> <i>Quinidine</i> <i>Disopyramide</i>	Bolus: 3-15 mg/kg in 30 min (max 100 mg) P: 20-80 mcg/kg/min	Lupus-like syndrome Hypotension Arrhythmias
	B	Shortened repolarization period Increased refractory period Decreased automaticity Minimal decrease in conduction AV block	Ventricular arrhythmias Digoxin intoxication	Lidocaine <i>Others</i> <i>Phenytoin</i> <i>Mexiletine</i> <i>Tocainide</i>	Bolus: 1 mg/kg (repeat dose each 10 min, max 5 doses) P: 10-50 mcg/kg/min	Bradycardia Hypotension CNS effects
	C	Increased refractory period Decreased cardiac heart rate Important reduction of conduction Prolongation of PR and QRS Decrease of LVEF	Supra ventricular arrhythmias. Atrial Fibrillation. Pre-excitaction síndrome. Ventricular arrhythmias	Propafenone Flecainamide	Bolus: 1-2 mg/kg in 15 min (max 140 mg) P: 4-8 mcg/kg/min Bolus: 2-4 mg/kg in 30 min (max 150 mg) P: 0.25-1 mg/kg/h	Hypotension Bradycardia Arrhythmias Hypotension Arrhythmias

Class	Mechanism of action and effects	Indications	Anti arrhythmic	Dose	Adverse effects
II	Beta adrenergics antagonist: Beta-blockers				
	Decreased heart automaticity Decreased Heart rate Decreased conduction speed Prolonged AV refractory period Decrease LVEF	SVT Ventricular Extrasystole	Esmolol Propanolol	Bolus: 0.1-0.5 mg/kg in 2-4 min P: 50-300 mcg/kg/min Bolus: 0.1 mg/kg c/6h IV in 5 min (max 1 mg/dose)	Hypotension Bradycardia Bronchospasm

Table 3. (Continued)

Class	Mechanism of action and effects	Indications	Anti arrhythmic	Dose	Adverse effects
III	Potassium (K ⁺) channel blockers Prolonged action potential Delayed repolarization Decreased heart rate	Reentrant arrhythmias Pre-excitation Syndrome Ventricular arrhythmias JET	Amiodarone	Bolus: 5 mg/kg in 20 mins (up to 20 mg/kg) P: 5-20 mg/kg/day	Thyroid toxicity Hepatic Toxicity Bradycardia Hypotension
			Solatol	Bolus: 1.5 mg/kg P: 2-4 mg/kg/day	Long QT
IV	Ca ⁺ channel blockers Decreased conduction speed Prolonged refractory period AV block	Atrial Arrhythmias Supraventricular arrhythmias	Verapamil	Bolus: 0.1-0.2 mg/kg in 2 min 2-3x doses. P: 1-5 mcg/kg/min	Hypotension Bradycardia Cardio pulmonary arrest
			Diltiazem	Bolus: 0.25 mg/kg in 2 min P: 0.1-0.3 mg/kg/h	Restricted use in children
Others	Slows conduction time through AV node, interrupting the re-entry pathways and restoring normal sinus rhythm	SVT	Adenosine	Bolus: 1st 0.1 mg/kg, 2nd 0.2 mg/kg, 3rd 0.3 mg/kg	Bronchospasm Prolonged asystole in heart transplant recipients
Others	Na and Ca intracellular bioavailability. Decreased conduction in both sinus node and AV node. Decreased sympathetic tone	Atrial Fibrillation Supraventricular arrhythmias	Digoxin	Bolus: slow 15 mcg/kg 5-10 min (up to 0.5 mg)	Bradycardia AV Block Ventricular Arrhythmia
	Alpha 2- agonist	Nodal tachycardia JET	Dexmedetomidine	Bolus: 0.5-1 mcg/kg in 10 min P: 0.2-0.7 mcg/kg/h	Hypotension Bradycardia Sedative

CARDIAC PACEMAKER

Temporal Pacemaker

Post-operative temporal pacemakers are routinely used after pediatric cardiac surgery. Bradyarrhythmias, complete heart blocks, AV asynchronicity and atrial overstimulation are some of the scenarios where pacemakers are useful.

Temporal bicameral pacemakers with epicardial leads are widely accepted for postoperative patients.

Programable parameters:

1. Voltage (mA): The energy emitted by the pacemaker to generate an electrical impulse in the heart.

Voltage range is between 0.1 to 25 mA, with an average starting point of 10 mA. This threshold must be evaluated daily and needs to be programmed 2 points above the threshold

for safety issues. This threshold represents the stimulus needed to create a P or QRS on the ECG that would produce a contraction.

2. Sensibility (mV): Refers to the capacity of pacemaker to detect the heart's own electrical activity. Range is between 0.4 to 20 mV. Average start points: Atrial: 0.5 mV, Ventricular: 2 mV. This threshold must be evaluated daily and set to half of the sensibility threshold. Sensibility threshold: minimal sensibility required to sense all P waves and all QRS complexes.
3. Frequency: The Cardiac Frequency a pacemaker provides.
4. AV Interval: Time between atrial to ventricle stimulation. It varies according to heart rate. Range between 50 to 300 msec.
5. Atrial tracing: The capacity to stimulate ventricle after a native atrial impulse.
6. Post ventricular atrial refractory period (PVARP): The time after a QRS in which the pacemaker cannot react to an atrial stimulus.
7. Maximum rate: Maximum rate of ventricular tracing that the pacemaker will reach. This depends on the total atrial refractory period (TARP) ($TARP = AV \text{ time} + PVARP$).

Pacemaker modalities are defined by three initial letters:

Stimulated chamber -Sensed chamber-Stimulated mode***

*Chambers: A: atrium. V: ventricle. D: dual O: none

**Stimulated Mode: Defined as the pacemaker's response to the detected cardiac activity.

I: inhibited. T: triggered. D: Dual. O: none.

The modality that should be used depends on the following factors:

1. If atrial/ventricular wire is available.
2. Type of arrhythmia (if the nodal function is preserved and the goal is to increase heart rate to increase cardiac output modalities with atrial sensing and stimulation are preferred (AAI/AOO). In case of AV block, an AV sequential modality is advised (DDD, DVI, VDD, VVI) (Figure 5).

Other Pacemaker Functions

Atrial overdriving pacing: could be used to revert reentrant tachycardias.

Reentrant atrial (Atrial Fibrillation): Atrial overstimulation (rate 10-30% faster). If the atrial capture is confirmed (when P waves of different shapes are seen), stimulation should be stopped.

Underdrive pacing (inducing a refractory period at the myocardial tissue involved on the reentrant circuit) or overdrive pacing (provoking an atrial anterograde depolarization) could terminate SVT.

Figure 5. Post-operative selection of Pacemaker modality.

DETECTION AND SOLUTION OF PROBLEMS

Stimulation failure: There is no electrical output nor pacemaker spikes on the ECG.

Reasons: Wire or battery dysfunction, crosstalk, inhibition or over sensing. These sensing issues can be solved by changing to asynchrony mode.

Capture failure: There is electrical output but there is not myocardial contraction.

Reasons: Myocardial fibrosis, ischemia, metabolic imbalance (hyperglycemia, hyperpotassemia, acidosis, alkalosis), antiarrhythmics.

Treatment: change polarity of the wires, correct underlying causes, check pacemaker output and refractory periods.

Sensed failure: Generated by the same reasons as those for capture failure.

It can be solved by correcting underlying causes, reviewing refractory times and sensed threshold set. Under-sensing could cause the pacemaker to compete with the intrinsically electrical activity. Over-sensing could cause the pacemaker to be inhibited and therefore cause ventricular pauses to appear.

Pacemaker wires usually start to fail after several days of being implanted, notorious especially after 5 days of being in place. The reason for this could be the inflammation generated in the surrounding myocardial tissue.

Pacemaker induced Wenckebach effect: This effect is produced as the atrial rhythm overcomes the maximum heart rate setting. P wave becomes closed and jumps into a PVARP, and the ventricular cable does not respond to this P wave. Adjusting the AV interval and the PVARP will increment the maximum rate and will avoid this.

Induced Pacemaker Tachycardia “endless loop”: On DDD or VDD, an endless loop tachycardia can be induced through a retrograde VA conduction. Usually it is started from a ventricular extrasystole that conducts retrograde to the atrium. If this activity is sensed by the pacemaker, an AV interval is generated and a subsequent ventricular stimulation is reached, leading to an endless loop tachycardia and perpetual AV node retrograde circuit. A none sense mode (DVI or VVI) or an increase in PVARP will finish the endless circuit.

Fibrillation Induction: If a stimulus under a unicameral asynchronous modalities (AOO, VOO) is generated and reaches the myocardial repolarization phase, an AF or VF can be induced. “Cross talk”: On Dual Sensed modalities a stimulus that is generated on one of the other wires is detected, and therefore the subsequent chamber stimulus is erroneously inhibited. A decreased sensibility or output intensity can terminate the error.

Other emergency alternatives: Transcutaneous pacemaker or Transesophageal pacemaker. Transesophageal pacemaker allows a transitory atrial pacing. It could easily move. Atrial capture output has to be >10 mA.

DEFIBRILLATION AND CARDIOVERSION

Defibrillation: Random non-synchronized shock: Used to treat ventricular fibrillation or pulseless ventricular tachycardia. Dose: 4J/Kg.

Cardioversion: Synchronized shock discharged with the next R wave. Used to treat SVT or ventricular tachycardia associated with hemodynamic instability or/and refractory pharmacological cardioversion.

Patch and paddles are used to monitor the rhythm before and after the shock is given. Both have the same thoracic impedance; however, patch is preferred since they are more secure and effective.

The contact surface between patch/paddles and thorax should be always be highest. Paddle/Patch should not be in touch with each other. Preferable positions are: Right infraclavicular position for the first one, and the second should be placed in the heart apex location or left middle axillary line. In small patients, one anterior and the other posterior is recommended. Usually there are use indications over the patch/paddles and they can be placed in inverted positions without problem.

Procedure

1. Turn on and select synchronic or non-synchronic mode
2. Check Rhythm. In the case that you need to use synchronized cardioversion, check sensing is adequate to capture R waves. If necessary, adjust sensibility.
3. Select amount of energy to use and charge.
4. Check rhythm and proceed to cardiovert or defibrillate if necessary.
5. Secure your surroundings, avoid health care personnel in contact with patient at the time of shock. Check for sources of free oxygen and continue with invasive mechanical ventilation.
6. Shock: Keep discharge bottom press until you can prove shock has been given. There could be a gap between the order and the discharge during synchronized cardioversion.

Cardiac Post-Operative Peculiarities

Paddle/Patch should be separated 12 cm from internal/DAI pacemaker. In patients with external pacemakers it is recommended to disconnect it before giving a shock.

ABSTRACT

The cardiac surgery operating room is an environment characterized by a high degree of complexity with respect to human-technological and human-human interfaces. Both aviation and surgery, in order to live in these environments, require integrated strategic planning. Leadership is crucial, and the lack of the latter can obstruct the “situational awareness” necessary for the prevention of mistakes and for recovery in critical situations, like in the case of Air France Flight 447 which crashed into the Atlantic Ocean on June 1, 2009 while traveling from Rio de Janeiro (Brazil) to Paris (France) [1]. Given that aviation is more advanced than surgery in the resolution of communication and leadership problems, many believe that among other surgeons and pilots, that transferring the systems from the first to the second helps substantially to approach its international security standard, even if it does not solve the problem in its entirety. In the following article, after analyzing two particular examples, we discuss similarities and differences between both activities; and we propose, thanks to the analysis of the literature, a foundation for understand. Good leadership recognizes problems, prevents and recovers from them, mainly without looking for blame.

In 1984, Perrow published his theory on “Normal Accidents”, exposing the complexity of interaction, where catastrophes are inevitable in complex systems that are intimately related. He predicted that in these scenarios mistakes can happen in many ways and are impossible to predict. The failure of a single component can have multiple consequences downstream, for example the complex patient that suffers various cycles of medical mistakes. In these systems there’s few possibilities of substituting or reassigning personnel due to the high level of specialization, closed personal communication and decreased comprehension of some processes [3]. According to Sigston, there is a point in any self-regulating organization, that once a level of stability is surpassed, it results in the collapse to the next hierarchical level. Close to, or when reaching this point, a change can happen that within itself is insignificant, but in a system it could lead to a massive, fast and disruptive transformation. This, which can be applied to the pathophysiology of carcinogenesis, can also be relevant for other topics within healthcare, per example, forgetting to give heparin to initiate extracorporeal circulation, causing total thrombosis of the circuit resulting in death of the patient. If we think in complexity, we would be able to solve problems that escape linear thinking. This prior statement coincides with the modern analysis of accidents: they are a result of an alignment of conditions and events, each single one necessary but none of them sufficient by themselves. If there can be mistakes within a system, it is complex. Even more, it is frequent that the best people commit the worst mistakes due to an excess of self-confidence (Psychological Complexity) [4].

2. PART 1: COMPLEXITY IN AVIATION AND MEDICINE: THE UNCERTAINTY OF FLIGHT AND SURGERY

As an introduction, the following two stories exemplify how the individuals did not comprehend the existing complexity due to a lack of a systemic focus.

1. Flight AF 447/2009 Rio to Paris: During this transatlantic flight, a storm formed ice crystals on the airspeed gauge (Pitot Tube), causing the autopilot to disengage. The two young pilots in charge, not fully understanding the problem, acted asynchronously and did not ask for help on time. At the last moment, the captain realizes the problem; unfortunately, it is too late. This accident was later explained through the black box recordings [1].

While analyzing this horrible catastrophe, it is notable how the intense psychological stress, which also occurs in cardiac surgery, tended to obstruct the part of the brain responsible for creative thinking. Immediately relying in the familiar, well-practiced, and usually ineffective protocols. The mistake resided in part because of the difficulties in communication between machine and man: the pilots were not trained for that eventuality (a stall alarm). Dynamic decisions in not fully understood critical situations require non-linear thinking.

2. A Patient in Cardiac PACU (Post-Anesthesia Care Unit). Back in the 1980’s, a surgeon from the US donated to a local institution in Argentina a series of pressure cuffs that compressed IV fluids to 300 mmHg. These were used to purge the catheter used for blood draws from an arterial line. Previously, the pressure cuffs used only

compressed to 170 mmHg. The nurses used this pressure to periodically flush the arterial line in order to prevent thrombosis. Every time the plastic sachet was half empty, the nurses would open it and let air in to provide volume and put on the cuff again. An accident never occurred due to the previous low-pressure system. After the introduction of the new models, there was a series of patients who underwent operations requiring cardiopulmonary bypass (CPB) and then, post-operatively, transferred to recovery, that once they were awake and neurologically intact, they were extubated. In these patients, after the blood was drawn for the arterial blood gases and subsequent flushing of the line, they started experiencing seizures, and in a few, coma. The directors of PACU, thinking in a linear manner, thought the root cause was in an inappropriately managed CPB or an inadvertent flush of air in the heart. It was not until they hired an external investigator, similar to the Line Operations Safety Audit in the aviation industry, to perform a comprehensive investigation [5]. What was observed was that the introduction of this new method of flushing the arterial lines introduced IVF fluids to such a high pressure that it surpassed the pressure in the aortic arch and injected air into the carotids.

“When you change the way you look at things, the things you look at, change.”

Max Planck 1918

3. COMPLEXITY IN THE OR

The Cardiac Surgery OR is an environment characterized by a high level of complexity with respect to the human-technological and human to human interfaces. These surgical procedures require coordinated efforts with multiple groups of people, all working under stress and time limitations (the longer the time the heart is static to fix a defect, the higher the mortality). The main, sophisticated technological factor is the extracorporeal circulation (ECC), in which both the coagulation cascade and the immunological interaction between blood and the plastic lines intervene, always unpredictable. The composition of the OR team is continuously changing, unlike the teams in the aviation industry, which can bring serious communication deficiencies going in and out of the ECC. Whether is low flows, complete cardiac arrest or flushing the heart, a minimal mistake can serious adverse events that can even lead to a coma.

It is known that cardiac surgeons make a life or death decision every 10 seconds during an operation. The majority would be in agreement that 75% of the outcomes are attributed to making the correct decisions and 25% in surgical technique. Surgeons should permanently maintain a conscience of the situation at hand, in other words, the degree of accuracy in which perception follows reality (situational awareness) [6].

Other sophisticated technologies that require similar control to that of aviation is ECMO (extracorporeal membrane oxygenation), which permits prolonging the ECC for various days outside of the operating, and “Cell Saver” blood conversation systems. It is because of these technologies that bloodless (i.e., without the need for transfusions) surgeries have been possible, even heart transplants and complex re-operative surgery. The transesophageal echocardiogram permits to control step by step the functional outcomes of off-pump heart surgery (i.e., cardiac surgery without the use of cardiopulmonary bypass or ECC) - it is the situational awareness, like flight controllers in aviation that enable such complex procedures.

Let us imagine the process of a heart transplant, and we will be convinced of how complex it can be.

By the end of the 1990's modern technologies emerged like the video-assisted robotics and combined endovascular techniques that are performed in hybrid operating rooms with intraoperative radiology. The actions of a team influence the necessities and functions of the others. All members of the Team should work in coordination having the same goal and technological interphase. Once again, a miscommunication can be catastrophic [7, 8].

4. SIMILARITIES AND DIFFERENCES BETWEEN AN AIRPLANE AND THE CARDIAC OR: LEADERSHIP IN BOTH

Both environments need integrated, strategical planning, with interdisciplinary microenvironments of professional development. Cardiac Surgery and the corresponding anesthesia practice in an OR with a "open door" to many people; aviation, on the other hand, practices inside a cockpit that are closed to the influence of other individuals.

The personnel in an airplane is usually smaller than that of a cardiac surgery OR: in a transatlantic flight three pilots fly in the cockpit, while in cardiac surgery 10 to 15 people from different specialties intervene during a case (surgeon, assistants, technologists, perfusionists, nurses, anesthesiologists, etc.). It has been estimated that around 100 individuals intervene in a complete perioperative period [6]. The teams involved are heterogeneous, even in their ways of communicating, however the complementation increases because of the subspecialties of skills involved. As the number of people involved increases, the complexity of their interactions also increases; the intricacies of inter-human relationships grow exponentially and not linearly, and therefore potentially reducing the quality of leadership [9]. The lack of leadership can impede recovery from mistakes in critical circumstances. Cardiac surgery is "Aviation and something more": human beings are more complex than an airplane, and they don't have a complete instruction manual.

Both fields require intense focus to be able to navigate a crisis or emergency situation, often with little information. Treating complications and emergencies can be compared to flying in a storm – an unpredictable scenario that most pilots avoid. Cardiac surgeons frequently encounter these situations, aortic ruptures and dissections are common examples. In the specialty of cardiac surgery there is a lot of unpredictability, and in cases of surgical emergencies, you have to fly, even with bad weather. This is a fundamental difference when compared to aviation, even though emergencies can always appear midflight. An example of excellence in leadership in aviation is the conduct of the pilots of US Airways flight 1549 "The Miracle on the Hudson" in which an Airbus A320, after taking off from LaGuardia Airport in New York struck a flock of Canadian geese. This resulted in a catastrophic engine failure and the need to land emergently in the Hudson River on January 15, 2009. The captain trained all his life for an eventuality that might never happened to him, the predictability of the unpredictable: landing in water [10].

In the cockpit, the pilots' functions are usually superimposed, to a certain degree (they allow substitution), in the OR it should be that way, however because of administrative and economic issues, this is not always the case. If the plane falls, the pilot falls with it. In commercial aviation there's multiple lives at risk; in surgery, there's only one (usually).

Accidents in aviation are public, highly noted and generate public demands for investigation and repairs. As a result, economic resources to investigate these incidents are more available, while in iatrogenic adverse events, it is completely the opposite (**Error! Bookmark not defined.**). Safety in medicine is considered a priority for some people in medicine, but is not considered an obligation for all [11].

In aviation, safety is the priority, and a safe landing, in which everyone walks away, is the only acceptable solution. For surgery, there's a broad spectrum of acceptable outcomes, most of time determined by the initial condition of the patient. It is important to remember that patients are different biologically, disease processes differ, and even sometimes we perform surgery on patients on the brink of death, not even knowing their initial condition. This scenario does not occur in aviation, where you always know your initial condition, and if they are not favorable you can simply cancel or delay the flight – or, at least in the setting of icy conditions, take the time to prepare and optimize for the journey as long as necessary to ensure a good outcome. While the concept of “optimization” exists in surgery, sometimes it is the unfavorable conditions that drive the need for urgent or emergent surgery – thereby, by definition, defining a situation of increased risk. Probably the closest analogy in the aviation world, is a plane taking off in the middle of a hurricane to prevent damage and loss of life from existing conditions in which the risk of remaining on the ground is greater than the risk of leaving – although, such circumstances are extremely rare.

5. TRANSLATIONAL CULTURE FROM AVIATION TO CARDIAC SURGERY

5.1. Culture of Safety: In the Air and in the Operating Room

The science of human factors, a prominent cornerstone in the aviation industry [12], has not yet found its place in Medicine; but it could still profoundly change the comprehension and execution of the decisions made in surgery [13]. Looking for the factors that are unpredictable or complex that relates both, specifically - human error - which often defines complexity. It drives to mistakes due to unexpected or misunderstood problems, if they exceed the cognitive capacity of the individuals or the Team [1]. In this day and age, in both medicine and aviation, society does not want to give room to mistakes – the concept of a learning curve does not exist, nor despite it's crucial historical importance, is barely acknowledged. Pilots, much like physicians, and especially surgeons, are expected to be perfect as soon as they complete their “simulation” training. But, experience and judgment develop and mature over time. This had entrusted doctors with the burden of understanding and dealing with the disease. Although it is known that they are human, new technological wonders have created an expectation of absolute perfection. Patients, who have the comprehensible necessity of considering their doctor infallible, have colluded (agreed) with these to deny the existence of the error and reject the uncertainty. However in medicine this has to be tolerated, since paradoxically, only uncertainty is definite [14].

Of course, the paradox in this concept is that while “pilot error” is often the final variable in most airline crashes, surgeons often be blamed for poor outcomes, despite the under-recognized reality that they often have very little influence on the final outcome other than

helping to guide a patient through an operation or hospitalization in which hundreds of providers have some impact on the final outcome. The closest analogy in the aviation world is recognizing the safe landing of a flight is determined by everyone from the baggage handlers, the ticket agents, to the flight attendants – and, of course, the mechanics.

Considering the error theory, there are authors who, like Fabri, assert that most of these are cognitive in nature [15]. Others, like Wiegmann, who analyze similar systems, propose that an error results from the disruptions of surgical flow provoked by miscommunications, external distractions, and failure of surgical equipment [16].

The culture that the aviation industry has in terms of safety is definitely something that could easily translate into surgery. The impossible to reach safety rate of the aviation industry (0.017/100,000 flights/year in the US) seduces the need for translation to healthcare. Especially with the medical institutes of the US estimate that yearly around 44,000 to 98,000 people die because of medical mistakes [17]. The report of not just accidents, but also of “near misses” is key in this. The CHIRP program (Confidential Human Factors Incident Reporting) permits the reporting of non-punitive human mistakes and near misses [18, 19]. This has been extrapolated to surgery with good results [11]. Helmreich, a psychologist dedicated to the study of human factors in aviation and surgery, has observed multiple surgical procedures in which he recorded many situations in which communication and team work are suboptimal, parallel to those observed in the cockpit. Rogers, an anesthesiologist and also a pilot, suggested that we do not let ourselves be seduced by moving unviable systems in a different environment [20]. On the contrary, Gaba, also a pilot and a pioneer of simulation in medicine, thinks that if concepts and practices from aviation cannot be transferred directly, it is possible and necessary for appropriate translation and adaptation [20].

Also, there is an existing observational audit translatable to the OR: LOSA or Line Operations Safety Audit, also a project of Helmreich [21] – see the following link for details (www.psy.utexas.edu/psy/helmreich/nasaut.htm). LOSA consists of an audit where expert observers sit down in the cockpit of normal flights to assess threats to safety, mistakes and their handling. These audits identified an average of two threats and two mistakes per flight. More than half of the mistakes were due to violations of already established rules – and finding that was somewhat unexpected.

5.2. Simulations

In aviation, every major incident is followed by a simulation of its causes to avoid a subsequent event, becoming a part of training. Moreover, there is a redesign of all equipment involved. In surgery, complications are considered habitual, and apart from being discussed extensively, they are not reported; most of the time due to fear of personal or professional repercussions or false sense of elevated (or need to preserve) self-esteem. In aviation, the simulators constitute a structured part of training, and surgery is catching up thanks to this. The pilots practice without risk, and they learn to develop strategies to recover from a mistake. They don't fly in airplanes in which they did not have extensive simulation training in first – and to which they are periodically and objectively re-tested. In cardiac surgery, as in other areas of surgery, there are multiple instances in which a surgeon has to operate for circumstances in which he/she has not trained due to multiple reasons – the least of which,

unlike flying in which a pilot can always abandon a flight, once an operation is started and the patient is placed on cardiopulmonary bypass, it is difficult to turn back without fixing the problem(s) at hand. Unfortunately, the complexity of biologic systems is almost impossible to simulate for now. These don't offer the same amount of realism that an aviation simulation would, despite extensive and growing literature attempting to simulate "real world" critical medical/surgical events. We can comfortably say we are still in very early and primitive in the field [22]. The future of surgical education is hybrid simulators between plastic materials and biologic organs. The sphere in which the greatest achievements in training have been obtained is in emergencies involving cardiopulmonary bypass – in part due to the mechanical nature of the technology [23, 24].

5.3. Sterile Cockpit Protocol

In commercial and military aviation, a compulsory protocol of a "Sterile Cockpit" was instituted during periods of high mental demand – specifically, during takeoff and landing. During a "Sterile Cockpit" there are standardized protocols for communication, language and call-back in order to decrease ambiguity. In 2010, Wadhera et al. translated these concepts to the Mayo Clinic, defining eight critical events during cardiopulmonary bypass, implementing the NASA Task Load Index, and decreasing significantly any potential opportunities for miscommunication [25]. Emphasis was made on communication during key actions, like clamping and unclamping of the aorta (i.e., intentionally stopping and re-starting the heart in a manner that limits myocardial injury and, all the while, maintaining adequate oxygenation blood flow to the remainder of the body). The authors concluded that unlike aviation, in cardiac surgery there's no exact time that can be conveniently defined as the main high risk or stress period for the whole team. In Figure 2, from Wadhera, the difference in mental demand in the OR according to the NASA TLI is demonstrated. However, unlike aviation, in cardiac surgery, high-stress situations are different for each component of the team at different times of the procedure. Also, cockpits are not equal: in an airplane it is closed and there's no intervention from the public; in the OR, the door is continuously opening and closing which permits entry and exiting.

Wadhera suggests that effective communication should be structured by defining periods of high mental tension and transferring the sterile cockpit concept to the operating room. The surgeon has to have more creativity than a pilot, not being able to put "autopilot", since a good "landing" (or weaning, to use the technical term) from cardiopulmonary bypass depends mainly on what has been repaired in the heart during the "surgical flight". Wadhera made emphasis to focus in critical events during the procedure rather than on defined periods: Heparinization/ starting CPB/ Aortic Clamping/ Cardioplegia/ Flushing / Stopping CPB. Interestingly, the cultures of operating rooms are often such the surgeon who insists on total silence during such key periods if often view negatively almost in a manner similar to flight attendants not understanding the need for pilots to singularly focused on landing an airplane and being unaware of the consequences of what happens if the plane does not land safely. In fact, most "bad outcomes" after surgery rarely occur in the operating room, even though operative events might initiate the path of a downward spiral that manifests much later in the Intensive Care Unit and often far away (in both time and distance) from those involved in the key triggering events.

Results of National Aeronautics and Space Administration Task Load Index (*NASA TLX*) show widely divergent cognitive workload measures during course of typical case. *CRNA*, certified registered nurse anesthetist; *CST*, certifies surgical technologist; *RN*, registered nurse; *Prep*, surgical preparation; *Postop*, postoperative.

5.4. NASA Model “Threat and Error” Applied to Cardiac Surgery

Hickey suggested considering each operation like a flight. He analyzed 524 flights/patients. He found 763 preoperative “threats” (atypical morphology, multiple lesions, comorbidities) in 72% of the patients (flights). Only 51% of these resulted in an error. In the remaining 257, he observed 430 errors in proficiency or judgment. In 173 (67%) of these, the mistakes were consecutive. Of those, in 60% (n=110; 21% of total), subsequent cycles of additional errors occurred. These cycles containing multiple errors were associated with surgical complications including death in 1.3%. The conclusion is that one unsolved error drives further cycles of errors and dangerous complications [26]. This coincides with the “Swiss Cheese” theory that is also parallel to the nuclear industry disasters (i.e., Chernobyl) and NASA flights that ended in tragedy (Challenger) [27]. In respect to medical mistakes, Hickey mentions that our profession has been stubborn on its focus, instead of adopting a systemic solution we have epitomized that of personal attacks, that at the same time discourages reporting and inhibits the investigation of systemic conditions that produce or result in an error that otherwise could be fixed – unless, of course, such “errors” can be directly attributed to the obvious actions (or inactions) of a single individual. He concludes that two thirds of errors are consecutive and a fifth of the patients suffer cycles of error that are associated with complications [26]. However, a pilot that crashes his plane – even if he/she survives – probably does not get to fly again, while the surgeon who experiences an intra-operative death is often expected to resume operating as if nothing adverse has occurred. Not to mention the rarely of the term “co-pilot error” when describing airline crashes and the potential similarities to medicine in which many providers have some impact on an eventual outcome.

5.5. Mission Analysis: “Crew Resource Management”

In the early 1980s, due to several aviation disasters, the concept of “CRM” or “Crew Resource Management” was developed in the United States to improve performance and promote safety [28]. These strategies to improve safety and teamwork can be translated to surgery [6]. In “Briefing and debriefing in the Operating Room using fighter pilot crew resource management”, McGreevy suggests two steps. In the first part, or Briefing (instructions), the military pilots explain in advance to their squad not only what they are going to do or expect what will happen, but what could happen and the measures to be taken in each case. In cardiac surgery, an example would be, if immediately after sternotomy a patient would become unstable, how to immediately initiating CPB would be considered or performed. The “debriefing” (reflection) is a wave of introspection similar to brainstorming about what went as expected or not – especially when such discussions involve equipment issues or a formal acknowledgement of those events that “went well” as opposed to those that did not. This is in order to avoid repeating mistakes (not to mention, praising good or effective Teamwork) but also suggesting a role in inducing a positive cultural change. In 2017, Powell-Dunford made a search in PubMed using the terms: Aviation, CRM, and patient safety. This search concluded in 22 relevant manuscripts [29]. Cardiac surgeons are described by McGreevy in 2007 as the fighter pilots of Medicine [30]. A key element in this process (rather than emphasizing the glamorous ‘movie star’ concept) is to identify mission objectives, benefiting from military CRM. Perhaps the most important thing is to emulate aviation by incorporating surgical specialty services in human factors and psychological aspects in patient safety (11). Investigation is essential in medicine; curiously, it has been historically specific to diseases and not to the study of errors, which are involved across diseases and specialties. Finally, video and autopsies in cardiac surgery would be the equivalent of black boxes in aviation – and yet, fewer and fewer autopsies are being requested, let alone performed, out of fear of finding something that the surgeon could have or should have done differently or better. The paradox is akin to trying to learn to be better when we prefer to not know the answers to the questions of why something did not go as planned.

6. PART 2: BIOETHICAL ANALYSIS: IS IT POSSIBLE AND SHOULD WE ATTEMPT TO REDUCE HUMAN ERRORS IN CARDIAC SURGERY WHILE IMITATING AVIATION?

6.1. Background and Theoretical Framework

The human error is an added product of human activity, and it can result in an unintentional chain reaction of tragic events. Even back in 100 A.C., the Latin proverb would say: “Errare Humanum Est” – translated into the commonly used term – “to error is human”. The modern concept of medical error arises mainly after the theories of Popper in 1967. His main school of thought was that knowledge grows by accumulation. Acknowledging mistakes and discarding old and wrong theories will provide a larger opportunity for growth. In “Conjectures and Refutations” [31] he referred to science, but a prior joint article with

McIntyre in 1983 [32] includes a powerful comment: “we must learn from mistakes, and how to look for them.” “Mistakes will help the scientist grow in terms of knowledge. Each one owes their enrichment thanks to others’ criticism, and being reasonable is to be prepared to listen.” Learning only from personal mistakes would be a long and painful process, and of unnecessary cost to patients. Experiences must be stored in such a way that doctors learn from the mistakes of others. We should not feel loss of self-esteem or shame to comment on mistakes to others. This philosophy is followed in Aviation, but why is it not the same in medicine? In 1990 James Reason [33] extensively studied the human error in nuclear centers such as Chernobyl and the Challenger tragedy (also discussed above). In 1994 [34] Mary Sue Bogner translated this knowledge to human error in medicine and that was the starting point for a tsunami of literature in the topic. The notion of malpractice-error is changing and also the guilt paradigm of the doctor due to the fact that in the majority of times variables not related to patients and procedures can be involved in certain deaths. In 1996, Marc de Leval asked about the role of human factors in medical outcomes [35, 36], and recalling Chernobyl, he postulates that a negative outcome can be observed and investigated as an accident. With the report, *to err is human, building a Safer Health System (IOM report 1999)* [37] there are no more excuses not to include this issue in hospitals and forcing the designing processes of care in order to avoid error.

Cardiac Surgery can be considered a complex social and technical system [38, 39] that assimilates that of high-risk businesses, such as the aerospace industry. The etiology of surgical errors is deeply enrooted in the effectiveness of teamwork. As discussed above, Wiegmann and colleagues postulated in 2007 that disruptions in team work was the only independent predictor of surgical errors [40]. Now a days, medical mistakes account for the third leading cause of deaths in the United States [41]. These issue are just being recognized, but hard to imagine being ‘new’, just in 2001 Carthey and de Leval [39] recognized that reporting critical incidents and near misses based on taxonomies of human error was in childhood stages in the field of Cardiac Surgery – while the rest of medicine was even less mature. After Makary published his work, the questions started to be asked: “why not investigate what aviation can teach us in order to reduce surgical mistakes?”

7. OUR PROPOSITION FROM KANTIAN ETHICS

In “Fundamental Principles of the Metaphysics of Morals”, Kant states: [42] “You may want your maxim to become a universal law”. We start to think what the good surgeon or the patient would like regarding the analysis and prevention of medical errors; which, as a human being, should be understood by all? This is reaffirmed by the position “To err is human, building a safer health system”. It is a categorical imperative. Kant says it when he writes: “The imperative says, what possible action for me is good, and represents the practical rule in relation to a will”. “The categorical imperative declares the action objectively necessary in itself” We must put ourselves in the place of the patients in general: would they want the services of a surgical “Team” to have a “Situational awareness”, controlling errors and disturbances of the flow during a procedure? Every rational man (or woman) would speculate that, like cockpit checklists, he/she could help. Summing up the Kantian thesis, the moral value of an act is not related to the result of it, but is valid if it is done or conducted from a

sense of duty or obligation. *Thus, a surgical error should be forgiven if there was ample pre-operative planning and care by the surgeon, regardless of the final result.* In fact, doctors have no obligation to results provided the system and processes are in place and function effectively to mitigate against such events – much like how airplane crashes are becoming less frequent and are more and more being considered “never events”. Extrapolating Kant to our day, we should try to prevent all errors, and in case of committing them, communicate them. In this Robert C. Mavroudis agrees, in an article referring to Kantian ethics and surgery in 2005 [43]. Society should defend the medical profession and not instigate or lead negative changes. This is how we come to the Platonic idea of virtue, which applies to society in its entirety. Physicians cannot be required to be more virtuous than the society from which they come. The extreme of this concept is reflected in the views of some that if a surgeon is not directly responsible for at least “some” deaths, then he/she is not giving enough patients the opportunity to extend their life in the face of challenging and complex problems.

8. FROM UTILITARIAN ETHICS

The English school of Utilitarianism bases its moral on the utility or result of an act before the motive. John Stuart Mill, disciple of Bentham, emphasized that the quality of “The Good” result matters. For him, “The Good”, widely constructed, is not only the good of the particular individual but that of the entire society. Mill insisted on the principle of equality, “what ultimately gives happiness is the sense that one was a good person who acted in accordance with his conscience by treating others well” (also in Mavroudis 2005) [43]. Thus, utilitarian ethics would also be in favor of doing everything possible to reduce human error in medicine. If the good has more weight than the bad, the act would be morally correct. Some believe that perhaps a combination of Kant and Stuart Mill would represent the ideal: an act well motivated by a Kantian imperative, with an acceptable result (Mill), and correctly communicating the results to the patient (Kant), and if there were future errors, rescue them (Kantian imperative and Millarian utilitarianism).

9. OTHER ETHICS

Santo Tomas de Aquino says, in “Bioética”, by Diego Gracia, p. 211 [44]: “The good of the people is more important than the good of one man”. “He who seeks the common good of the multitude, consecutively seeks his own particular good”. It would seem that Miller took it from Santo Tomas. This justifies this proposal, given that through research in aeronautics, by means of translation, it will be possible to reduce the incidence of errors in the operating room.

In the “Emilio” by Rousseau, it states: “Historical societies are the consequence of a BAD social contract, but it is not said anywhere that it is not possible to build a new society on a GOOD social contract” [44]. Would this new contract be one of goodwill, where doctors learn from our mistakes and we can communicate them without fear? (McClityre and Popper, 1983) [32].

10. COMMENT

Although it is universally known, as mentioned above, that “Errare humanum est”, reinforced by the “To err is Human” of the NHI, 1999 [37]. The standard of medical practice has evolved to the point where only perfection seems to be accepted by the public, as people are impressed by the current safety in commercial aviation. This also seems to be the opinion of the press. This feeling was instilled in medical surgeons through medical school and residency. The science of human error is not taught during the curriculum in medicine, students are allowed to believe that error is avoidable and that every mistake is error – and a concept informally emphasized in some training programs that despite their actions, inactions, and co-morbidities, patients should not be held accountable for their own outcomes. Surgeons do not have the power to control all results, even in intensive care units. Mavroudis reported in 2005, 1.7 errors were committed per day per patient in an intensive care unit in the USA [43]. Therefore, it is a “categorical imperative” to prepare comparative works of this type. Not doing it would be, according to Banja, entering a medical narcicism [45] and making us believe that we are all perfect. For the public, cursing to the individual is more emotionally satisfying than blaming institutions, but this is not the way to be better [33].

SUMMARY AND CONCLUSION

1. Both, cardiac surgery and aviation develop in complex environments.
2. Given the more heterogeneous human environment, added to the greater number of personnel involved in the operating room and the greater biological variability of the human being, the possibilities of error in cardiac surgery are more unpredictable.
3. Aviation has become more methodical and systemic to solve safety issues, and there are various reasons for that: the pilot’s life is at risk, tragedies are public and there are more resources to investigate – not to mention the consequences, both in terms of lost of life and the financial costs (direct and indirect) of a crash are substantial. Nevertheless, aviation accepts the inevitability of an error – but still strives to avoid them.
4. Physician tend not to recognize error or fatigue, and together with patients make a pact to acknowledge this. Systems must be put into place to recognize and appropriately manage both. Unlike how pilots are restricted in their work hours and conditions, the surgeon/hero is often a martyr to endless work hours in extremely adverse conditions. As a society, medicine must overcome this cultural barrier.
5. Adopting the systems from aviation and translating them to surgery gets everyone closer to a standard and culture of safety, even though it does not solve the whole problem. Research on human factors, especially the psychology of safety, has a very important role that we must develop, enlarging the “islands of excellence in a sea of invisible faults”.

Chapter 459

THE EARLY HISTORY OF TREATMENT OF KERATOCONUS BY SURGERY

T. Jurkiewicz^{1,}, C. Fabio¹ and A. S. Marty²*

¹Lyon, France

²Bordeaux, France

ABSTRACT

Keratoconus had been described for the first time in 1748 by a German oculist, Buchard Mauchard, who named this disease “staphyloma diaphanum”, but it was in 1854 that John Nottingham made the first complete description of the pathology.

The first treatments were intended to stop the progression of the disease. Doctors created ointments based on plant extracts or molecules. It was also at this time that the first surgical protocols appeared, aimed at increasing visual acuity and reducing the cone.

For this purpose, several protocols have been developed in the early and middle 19th century in order to modulate the shape of the iris or to create scar tissue at the cone. The first surgical approach was resting on pupil displacement and change of the shape of the iris to increase visual acuity. The second surgical approach was developed from the mid of the 19th century. These protocols relied on the creation of corneal scars or the removal of the cone-containing part to modify its shape.

But these interventions showed unreliable and contradictory results and were gradually abandoned. The first major revolution in the surgical management of these patients came with keratoplasty.

Keywords: history, keratoconus, surgery, iridotomy, cauterization

1. INTRODUCTION

Our current knowledge gives us a better understanding of the apparition mechanism, risk factors, and treatments of keratoconus, but during the 18th and 19th century, it was a less known, and misunderstood disease. Its causes were still mysterious and the treatments were disputed.

The first data about this disease came from the doctoral dissertation of a German oculist, Buchard Mauchard, written in 1748 [1]. He wrote the first known report on this ectasy which he called “staphyloma diaphanum”. But it was not until 1854 that a first clear description of keratoconus was made by John Nottingham [2].

In the 19th century, the lack of theoretical knowledge and the difficulties of exploring visual function led to the formulation of several contradictory hypotheses on the causes and consequences of this disease.

Indeed, a limited number of tools available for the cornea’s functional exploration have led to two theories. The first considered keratoconus as a thickening of the cornea, with several authors including Adams and Himly then naming it hyperkeratosis [3, 4].

The second hypothesis was that the keratoconus causes a thinning of the cornea and was defended by Wardrop, who was also the first to evoke it [5]. His hypothesis has been confirmed a few years later in 1830 by Rudolph Wagner when performing a corneal dissection of a keratoconus patient. He mentioned a thinning of the stroma at the cone’s level [5]. Hulke performed a second dissection in 1859 and describe a thinning of the anterior elastic lamina (now called Bowman’s membrane) [6, 7].

Finally, some authors mentioned a keratoconus comorbidity with intraocular hypertension, which, according to them, would explain the corneal deformation [8]. Other authors evoked a keratoconus associated hypotonia [6, 9].

In that time, doctors also suspected a link between the disease onset, the use of accommodation and a higher blood flow at the head level, which make them believe of a possible predisposition for some trades such as seamstress, or cook [5, 10].

Regarding the disease’s probable causes, several hypotheses have been already mentioned like genetic component presence. The descriptions of familial cases of keratoconus present in the literature at this period support this particular track.

Other factors are also highlighted such as the simultaneous apparition of certain diseases, alcoholism or being generally vulnerable [5].

Authors also tend to agree on the disease onset, which occurs most often in the youth and early adulthood, but may also occur later, in rare cases up to 50 years [10]. Its discontinuous progression has already been mentioned [3].

The first statistical study on keratoconus prevalence happened in 1850. Prevalence can be defined as a measure of a population’s health status. It is the total number of disease’s case at a certain moment or over a given period. For a pathology, prevalence is determined by relating the present number of disease case to the studied population.

This study by Dr. White Cooper included all cases of keratoconus detected in different hospitals or clinics that he was informed of (between 1824 and 1850). These data mainly concerned institutions located in the United Kingdom but also in Macao.

He concluded on a general prevalence of keratoconus of 1/1 077, out of 208 970 cases that he could compile on the basis of the transmitted results. He had already evoked at the

time a different prevalence of the disease in different countries, but these results were unreliable.

He found a prevalence of 1/1 090 in London against 1/4 515 in Scotland, or 1/405 in Dublin. He also mentioned a trend toward increased prevalence in warmer countries and in Asia, based on the prevalence he had obtained for Macao (1/308) [3, 10, 11].

This study prefigured modern studies about keratoconus epidemiology, as the overall proportion found here is not far from certain current studies. But many factors must also be taken into account: although the mentioned hypotheses are still relevant, detection tools were not reliable, the medical staff was not always well trained, especially for this rare disease, access to care was difficult for some populations and the living and environmental conditions were also very different at the time.

All of this proves us that the knowledge of that time was rather weak and blurry even if it seemed that an evolution was starting. The numerous and contradictory hypotheses supported by the different researchers could lead to misunderstandings and the creation of treatments which were at best useless and at worst could cause an eye loss, as we will see later.

2. TREATMENT OF KERATOCONUS IN THE 19TH AND EARLY 20TH CENTURY

Treatments could be divided into different categories: optical treatments, medical treatments, and surgical treatments.

2.1. Optical Treatments

The first optical treatments were not recognized as effective because of that time's technological limitations, preventing the creation of glasses optimally correcting strong ametropia (including astigmatism that poses the most problems in the correction) [3, 12].

However, glasses were still recommended at least in the early stages of the disease where they could still be useful [13, 14].

2.2. Medical Treatments

These treatments consisted of instillations of certain substances in the form of miotics, aiming to reduce the ocular tension or to put the pupil in miosis.

Irritating topicals (like infusions of tobacco leaves, zinc sulphate solution ...) were also in use; nevertheless these treatments had debatable effects with many possible undesirable effects.

Some other treatments described as "hygienic" consisted in a set of recommendations, such as walks and accommodation, for reducing the disease progression rate.

Eye compression by a rubber band, with or without the complementary use of miotics, was another medical treatment that was profusely cited by many works of the late 19th century.

2.3. Surgical Treatments

For the doctors, surgical treatments represented the most solid and effective way to treat keratoconus. Many protocols were set up with different goals, including corneal flattening and restoration of vision.

The first surgical techniques were developed in the early and middle 19th century: most of them relied on pupil displacement and iridectomy (change of the shape of the iris, also called iridodesis) to increase visual acuity.

2.3.1. First Surgical Attempts at the Beginning of the 19th Century

Lowering the Eye Tone

Considering that an ocular hypertonia could be the origin of keratoconus, some surgeons proposed protocols to lower the tension. Wardrop submitted a protocol based on the puncture of the anterior chamber several times through the top of the cone, but this technique did not allow a maintained flattening of the durable cone. Indeed, as soon as the punctures stopped the cornea resumed its shape [5].

Displacement of the Pupil

In 1840, Tyrrell moved the pupil to the periphery so that the patient could use a corneal area with normal curvature.

He made an incision in the anterior chamber and drew the iris to pass through it. He then excised the prolapse part of the iris: the pupil obtained was more or less regular at the periphery. But there were many accidents (like ocular inflammation due to herniation of the iris, or increased intraocular pressure, making an iridectomy mandatory for these patients, which affected a little more their vision) [15].

Iridectomy

Other procedures were attempted in a similar approach such as sectioning a small portion of the iris to allow reuse of a corneal portion unaffected by keratoconus. This procedure was used by surgeons such as Bowman or Walton, who recommended it in the early stages of the disease in addition to wearing an optical correction [16].

This operation's purpose was for the patient to reuse unused corneal portions with normal curvature to improve his vision. Several surgeons have tried this procedure with variable and non-reproducible results [3, 5]. This procedure was also used complementary to other surgical procedures [17].

Iridodesis

Donders was the first to consider the idea of suppressing ametropia by using a pinhole, made with a diaphragm pierced with a hole or a thin slit.

But it had disadvantages for orienting oneself into space with far vision to go into space because of the very limited visual field [18]. Bowman drew inspiration from this work to design a protocol to reduce the pupillary opening to a narrow slit like a cat pupil that he named “iridodesis” [19].

He opened the anterior chamber at both ends and incarcerated the iris in the two incisions to obtain the deformation of the iris in a narrow slit.

Critchett picked up the idea of incarcerating the iris only on one side, forming a simple iridodesis [5, 20].

However, these procedures caused many accidents and inconveniences because of the incarceration of the iris in the sclero-corneal limb. Moreover, there was a great risk of causing a glaucoma via the hernia iris.

2.3.2. Techniques Developed from the Mid of the 19th Century

Other techniques were developed around the middle of the 19th century following the failures of the previously mentioned methods. These new techniques relied more on the creation of corneal scars or the removal of the cone-containing part to modify its shape.

They were based on observations of patients with hydrops, who, after healing and a period of time to decrease opacity, got a better acuity with a less conical corneal shape.

Creation of Scar Tissue

Several surgeons have relied on cases of corneal scarring that have reduced the curvature of the cornea:

De Graefe's procedure consisted of creating a scar to try to smooth the cornea. He excised a corneal flap 2 to 3 mm long without penetrating the anterior chamber.

After two days of rest for the patients, he cauterized the wound chemically with a silver nitrate pencil during three to four days. After this stage, he completely crossed the cornea and repeated this process for a few days before allowing the cornea to heal, causing a whitish scar to appear [5, 21].

Many variations of this method have emerged: [22] Meyer, for example, modified the protocol by no longer excising the vertex of the cone but performing lateral excision [19, 23].

Bowman, in order to avoid painful daily cauterization, suggested to replace the excision of the cornea by the trepanation of almost the whole thickness of the cornea [18].

Finally, tattooing techniques were created, using the perforation of the cornea with needles coated with Indian ink [24]. But all these methods provoked the appearance of a corneal leucoma causing a strong loss of visual acuity for the patient.

Compression Healing

Another surgical technique involved the section of an oval area of the cornea at the center whose edges were approximated by the use of a silver wire. But the use of these wires could lead to numerous infections and edematous complications [5].

Therefore other surgeons preferred trying to heal by compressing the cornea to avoid them [12]. The operated eye was covered with a cloth and compression was performed with a rubber band.

Finally, one of the derived techniques consisted of the total section of an oval zone of the cornea not in the central part but in the lower middle part and the use of compression to help the healing of the cornea.

After this procedure, the vertex of the cone moves from a central position to a lower corneal position and decreases. The cornea resumed a form closer to normal according to the authors [23, 25].

Creation of Scar Tissue by Corneal Cautery

Another procedure derived from the creation of corneal scar is used by the French surgeon Gayet. He preferred this method because it made it possible to avoid the disadvantages of nitrate, whose action is difficult to limit once applied and which could be printed in the cornea. One of the main objectives of this method was to reduce the size of the scar while keeping the efficiency of the cautery process.

Other surgeons quickly adopted the use of thermo-cautery or Galvano-cautery and several derivatives of this protocol were created [3, 26].

Some surgeons used this method with perforation of the cornea by cautery [27] but this had serious consequences including cases of glaucoma.

Non-perforated corneal cauterization protocols have been developed with the aim of reducing these undesirable effects: the risk of developing glaucoma could then be reduced while keeping the efficiency of the process [19, 28].

After reviewing them, we can say that all these methods caused the occurrence of a more or less central corneal scar. Visual acuity was mostly decreased instead of being increased, causing visual discomfort. Some methods were as long and painful as the De Graefe or Bowman procedure and caused a central scar preventing any vision with the operated eye. Moreover, the cornea remained irregular with strong astigmatism and the results of these methods remained difficult to predict.

The various surgical procedures enumerated so far exposed patients to serious complications in the iris and cornea with delicate operative procedures.

Even if the operation was successful with sagging of the cone, the results obtained in the visual acuity were poor because of strong astigmatism but also because of the corneal scar created.

CONCLUSION

At the end of the 19th century and the beginning of the 20th century, several surgical approaches for treating keratoconus remained: one of the most common is a synthesis of medical procedures (compression and use of myotic) and surgery in cases of aggravation (cauterization or scar tissue creation).

However, these methods did not guarantee good vision and a conservation of the patients' ability to remain autonomous because of possible residual corneal scars, but also of possible adverse effects (like infections or glaucoma). Improvement in glasses manufacture at the end of the 19th century made the increase of patients' visual acuity possible. Although important progress has been made during these centuries, the prognosis of patients remained bad in the long term. It is only in the first half of the 20th, after the possibility of performing corneal

transplants with better success rates was developed, that surgeons have been able to provide a more perennial solution to their patients, thus making it possible to stop the disease while preserving a certain visual acuity. The first corneal transplant was performed in 1901 by Dr. Zinn. But it was not until 1936 that a corneal transplant in an advanced case of keratoconus was successfully performed.

THE RETROSIGMOID APPROACH: FROM THE MICROSURGICAL ANATOMY TO THE SURGERY

***Francesca Graziano, Enrico Lo Bue, Lara Brunasso,
Alessia Lombardo, Rosario Maugeri and Domenico G. Iacopino***
Neurosurgical Clinic, AOUP “Paolo Giaccone”, PostGraduate Residency Program in
Neurosurgery, Department of Biomedicine Neurosciences and Advanced Diagnostic
(BiND), School of Medicine, University of Palermo, Palermo, Italy

ABSTRACT

The retrosigmoid approach has been widely described and utilized for access to various pathologies of the posterior fossa and the cerebellopontine angle. This approach gives a better view of the CPA and allows early identification of various neurovascular structures, more complete removal of lesions, less morbidity, and better functional results in terms of cochlear and facial nerve preservation. Many authors advocate it as the procedure of choice during vestibular nerve section, microvascular decompression, surgery for vestibular schwannomas, non-acoustic tumors, or insertion of auditory brain stem implants.

1. MICROSURGICAL ANATOMY OF THE CEREBELLOPONTINE ANGLE

In skull base neurosurgery, the retrosigmoid approach has been widely described and utilized for access to various pathologies of the posterior fossa and the cerebellopontine angle [1]; thus, it was defined by Mostafa B E et al. as the keyhole to the Cerebello-Pontine Angle (CPA) [2]. The cerebellopontine angle is located between the superior and inferior limbs of the cerebellopontine fissure formed by the petrosal cerebellar surface folding around the pons and middle cerebellar peduncle [3]. This approach gives a better view of the CPA and allows early identification of various neurovascular structures, more complete removal of lesions, less morbidity, and better functional results in terms of cochlear and facial nerve preservation [2]. Surgery of the posterior fossa has evolved over the years with a shift toward a more

minimally invasive approach [4]. Many variations of the technique have been described to tailor the procedure in relation to patient's pathology [5, 6]. Many authors advocate it as the procedure of choice during vestibular nerve section, microvascular decompression, surgery for vestibular schwannomas, non-acoustic tumors, or insertion of auditory brain stem implants [5, 6].

1.1. Osseus and Muscular Relationships

When dealing with cerebellopontine angle approaches, surgeons initially confront the occipital and temporal bones and their related structures. Careful exposure, in particular of bony sutures and others osseous prominences and depression, enables these sites to be used as important landmarks for surgical orientation and for restricted and appropriate CPA approaches (Figure 1) [7]. The occipital bone, situated at the back and lower part of the cranium, surrounds a large oval aperture, the foramen magnum, through which the cranial cavity communicates with the vertebral canal. The convex external surface of occipital bone has several prominences and lines on which the muscles of neck attack. The largest prominence, the external occipital protuberance or inion, is situated at the central portion of the external surface. A vertical ridge, the external occipital crest, descends from the inion to the midpoint of the posterior margin of the foramen magnum, with the nuchal ligament attached. Along the superior nuchal lines, which extend laterally and horizontally from the external occipital protuberance, the trapezius muscle inserts medially and the sternocleidomastoid muscle inserts laterally. The splenius capitis muscle, partially covered by the trapezius and sternocleidomastoid muscles, inserts on the lateral third of the superior nuchal line. The inferior nuchal lines run laterally from the midpoint of the crest. Below each inferior nuchal line, the rectus capitis posterior minor and major muscles are inserted, respectively, medially and laterally. The semispinalis capitis muscle inserts in the area between the superior and inferior nuchal lines and is situated, with the longissimus capitis muscle, deep to the splenius capitis and sternocleidomastoid muscle. Therefore, there are 4 muscular planes, which are from surface to depth: sternocleidomastoid and trapezius muscles; splenius capitis muscle; semispinalis capitis and longissimus capitis muscles; rectus capitis posterior minor, rectus capitis posterior major, inferior oblique and superior oblique muscles. The suboccipital triangle (SOT) is formed by 3 of the 4 muscles of the deepest plane: medially by the rectus capitis posterior major, laterally by the superior oblique muscle, and inferiorly by the inferior oblique muscle (Figure 2) [8]. The internal concave surface of occipital bone, in particular of the squamous part, is deeply concave and has a prominence, the internal occipital protuberance, near its center. The *cruciform eminence* divides the endocranial surface of the occipital squama into four fossae. The *internal occipital protuberance* lies at the center of the cruciform eminence. The *internal occipital crest* is the inferior arm of the cruciform eminence. *Transverse sulci* form the transverse arms of the cruciform eminence. The occipital bone articulates with six bones: the two parietals, the two temporals, the sphenoid, and the atlas. The lambdoid, occipitomastoid, and parietomastoid sutures are united at the asterion and separate the occipital, parietal, and temporal bones (Figure 1) [7]. The asterion has been widely used as a landmark for all posterolateral approaches to the cranial base. Classically, the asterion has been cited as an external landmark for the transverse sigmoid junction (TSSJ). The relationship between the cranial sutures and

venous sinuses can be used in surgical planning [7]. Posterior fossa craniotomies can constitute a risk of injury to the sinus complex due its location [9]. Localization of the venous sinuses, TSSJ and emissary vein is of utmost importance in the retrosigmoid approach to avoid damage to the venous structures of the region [10].

1.2. CPA and Its Compartments

1.2.1. CPA Upper Neurovascular Complex

In the CPA, identification of the cranial nerves that arise from the brainstem and of their vascular relationships within the upper, middle and lower aspects of CPA cisternal space is mandatory [7]. The CPA neurovascular complex includes the pons, trigeminal nerve, supracerebellar artery (SCA) and superior petrosal veins. The most common operation directed to the upper neurovascular complex is exposure and decompression of the posterior root of the trigeminal nerve. The posterior trigeminal root joins the brainstem about halfway between the lower and upper borders of the pons [7]. Today, it is generally agreed that the most common cause of classical trigeminal neuralgia TN is compression of the trigeminal nerve by a blood vessel, usually an artery, in the cerebellopontine cistern. This phenomenon is commonly referred to as neurovascular conflict. A neurovascular conflict should be

considered a normal neuroanatomic variant in patients with facial pain not fulfilling the TN diagnostic criteria [11]. More than one artery can compress the nerve. In a few cases the SCA will compress the rostral surface of the nerve and the anterior inferior cerebellar artery (AICA) will compress the caudal surface [7]. The SCA arises in front of the midbrain, usually from the basilar artery near the apex. It passes below the oculomotor and trochlear nerves and above the trigeminal nerve to reach the cerebellomesencephalic fissure [3].

The transverse pontine veins are the most frequent veins to compress the trigeminal nerve. The transverse veins are tributaries of the superior petrosal veins, the largest and most frequently encountered veins in the posterior fossa.

1.2.2. CPA Middle Neurovascular Complex

The middle complex includes the AICA, pons, middle cerebellar peduncle, cerebellopontine fissure, petrosal surface of the cerebellum and the abducens, facial and vestibulocochlear nerves. The AICA originated from the Basilar artery (98.1%) or from the vertebral artery (1.9%) as a single (92.3% of CPAs) or duplicate (7.7%) artery [12]. It courses together with the abducens, facial and vestibulocochlear nerves to reach the surface of the middle cerebellar peduncle, where it courses along the cerebellopontine fissure and terminates by supplying the petrosal surface of the cerebellum.

In most cases, the AICA passes below the facial and vestibulocochlear nerves as it encircles the brainstem. However, it may also in other cases pass above or between these nerves in its course around the brainstem. The veins on the side of the brainstem that have a predictable relationship to the facial and vestibulocochlear nerves are the veins of the pontomedullary sulcus, the veins of the cerebellomedullary fissure, middle cerebellar peduncle and cerebellopontine fissure.

Operations directed to the middle complex are for the removal of acoustic neuromas and other tumors and for the relief of hemifacial spasm. The facial and adjacent cranial nerves are the neural structures at greatest risk during acoustic neuroma removal. The facial nerve is stretched around the anterior half of the tumor capsule. The nerve infrequently is found on the posterior surface of the tumor [3].

1.2.3. CPA Lower Neurovascular Complex

The lower complex includes the posterior inferior cerebellar artery (PICA), the medulla, inferior cerebellar peduncle, cerebellomedullary fissure, suboccipital surface of the cerebellum, and the glossopharyngeal, vagus, spinal accessory and hypoglossal nerves.

The PICA arises at the medullary level from the vertebral artery, encircles the medulla, passing together with the glossopharyngeal, vagus, spinal accessory and hypoglossal nerves to reach the surface of the inferior cerebellar peduncle. The glossopharyngeal, vagus, spinal accessory, and hypoglossal nerves arise from the medulla along the margin of the inferior olive. The PICA has a complex relationship to these nerves. The proximal part of the PICA passes around or between and often stretches or distorts the rootlets of the nerves in the lower complex. At the anterolateral medulla, the PICA passes around or between the rootlets of the hypoglossal nerve. At the posterolateral margin of the medulla, it passes between the fila of the glossopharyngeal, vagus and spinal accessory nerves. The vertebral artery courses anterior to the nerves in the lower neurovascular complex. The hypoglossal rootlets usually pass behind the vertebral artery. However, some hypoglossal rootlets infrequently pass

anterior to the artery. If the vertebral artery is elongated or tortuous and courses laterally to the olive, it will stretch the hypoglossal rootless over its posterior surface. The close relationships of the PICA and vertebral artery to the glossopharyngeal and vagus nerves makes it logical to explore these relationships in glossopharyngeal neuralgia. The glossopharyngeal nerve arises as one rootlet from the upper medulla, just caudal to the origin of the facial nerve. In a few cases, however, it originates as two rootlets, which can remain separate through their course to the dura. The vagus nerve arises below the glossopharyngeal nerve and is composed of multiple combinations of large and small rootlets [13]. It may be difficult to distinguish the lower vagal fibers from the upper accessory rootlets because the vagal and cranial accessory fibers usually enter the vagal meatus as a single bundle. The rootlets forming the hypoglossal nerve arise in a nucleus whose rostral portion sits deep to the hypoglossal triangle in the floor of the fourth ventricle.

2. THE RETROSIGMOID APPROACH: A STEP BY STEP DESCRIPTION

2.1. Patient Positioning

The patient is placed supine or in the park-bench or sitting position [7]. Most patients are placed in a supine-oblique position, where the patient lies supine with the shoulder that is ipsilateral to the tumor elevated enough to allow the head to be turned parallel to the floor with no excessive tension on the neck [14]. A sand bag or a foam roll can be placed under the ipsilateral shoulder to minimize rotation of the neck [7]. The patient's head is rotated toward the contralateral side and is supported on a Mayfield three-point fixation device to obtain simultaneous flexion and rotation [7]. If the patient's body habitus (e.g., significant limitation of neck motion) precludes this positioning, the modified park-bench position can be considered, where the patient is placed in a lateral position with the head supported outside the surgical table by the Mayfield head holder. The dependent arm is then supported on a swing attached to the Mayfield and an axillary roll under it prevents brachial plexopathies. The ipsilateral shoulder can be taped to minimize its profile [7]. The use of sitting position has almost been abandoned because it is associated with a significant risk of air embolism, even if it offers a clean surgical field because blood and CSF drain away from it. Here, the head is slightly fixed and rotated toward the ipsilateral side [7]. The sitting position can be uncomfortable for the surgeon, leading to early interruption of the procedure. Instead, in the supine position or the modified park-bench position the operating table is turned so that the surgeon can sit behind the patient's head with his or her feet under the table. An armrest for the surgeon is also placed for the arm nearest the vertex [7].

2.2. Skin Incision

The skin incision consists of a 4–5 cm curvilinear skin incision made at the retroauricular region, and it was made to cross over the asterion at the upper third point of incision, being 1–2 cm lateral to the greater occipital nerve and just medial to the lesser occipital nerves [15]. The inferior limb of the skin incision was directed laterally to avoid direct or indirect injury to

the lesser occipital nerves [15]. The operative field became deeper with a linear skin incision because of the thickness of the subcutaneous tissue when retracted. Accordingly, the curvilinear incision was preferable for closing up the operative field after retracting the skin flap [15]. As the operative results have improved remarkably, the patients have begun to focus on the postoperative discomfort around the craniectomy site. One major drawback of the conventional retrosigmoid craniectomy is a possible (7–50%) postoperative headache due to the long skin incision and the large craniectomy [15, 16, 17, 18, 19, 20, 21]. Such postoperative headache may occur by adhesion of cervical musculature to dura mater with the resultant traction during neck motion, injuries to greater and/or lesser occipital nerves, or chemical meningitis by bone chips during drilling [21]. To reduce the rate of such complications and thereby improve surgical outcomes, various skin incisions and scalp flaps have been proposed as possible alternatives to the standard straight or S-shaped approach (Figure 1) [22].

To reduce postoperative headache and scalp and neck discomfort from injury to these nerves, a modified technique for a 4-cm C-shaped skin incision was developed and initially tested by Salvatore Chibbaro [23]. This modified skin incision has a medial convexity and is usually placed 8 cm laterally to the external occipital protuberance (EOP) and medially to the mastoid groove and the pinna, with the lower edge terminating 1.5–2 cm above the mastoid tip [23]. The main neural structures at risk when performing the skin incision for a minicraniotomy via retrosigmoid approach (mCRSA) are the lesser occipital nerve (LON) and the greater auricular nerve (GAN) [24, 25]: the LON runs approximately 7 cm lateral to the EOP and 3 cm medial to the mastoid process tip and provides sensorial innervation of the occipital, mastoid, and temporal regions; the GAN may have a mastoid branch running approximately 9 cm lateral to the EOP, whereas the principal trunk may be located 1 cm above to the mastoid tip [24, 25]. Following a careful subperiosteal dissection, the muscle flaps are then reflected superiorly and inferiorly and retracted with stitches. After creation of a burr hole at the transverse- sigmoid sinus junction [23], a circular craniotomy approximately 2.5 cm in diameter is done, exposing the underlying dura mater, which is opened in a C-shaped fashion with the base protecting the sinus junction [23].

Asterion is a precise landmark for determining the skin incision and localizing the apex of the triangular craniectomy. It has been defined as the junction of the lambdoid, parietomastoid, and occipitomastoid sutures [27, 28], and it is easily identified as the site of slight digital depression which could be palpated through the skin behind the mastoid process at the level of zygomatic root (on the extending line from the zygomatic root to the superior nuchal line).

2.3. Bone Drilling

A retrosigmoid craniectomy usually extends from the lower margin of the transverse sinus down to the foramen magnum, behind the sigmoid sinus. In the past, the main concern during the retrosigmoid approach for CPA lesions was focused on the preservation of VIIIth and VIIth cranial nerves [15, 16, 20]. A circular craniectomy is made below asterion, overlapping the back portion of mastoid process, using a 6 mm-steel burr and a 4 mm Kerrison rongeur. The craniectomy 2 cm in width is enough to explore around V nerve or VII–VIII nerve complex and to achieve a total removal for the CPA tumors (such as

vestibular schwannomas, meningiomas or cholesteatomas), while the craniectomy is a little bit enlarged downward to explore the lower CPA. A steel burr is mainly used until exposure of dura mater, while a diamond burr and Kerrison rongeurs are used for resecting the marginal inner table of the skull. The lateral border of the triangular craniectomy is approximately at the posterior margin of the sigmoid sinus, while the upper border is approximately at the inferior margin of the transverse sinus. Usually, bony removal over asterion proceeded to delineate the transverse-sigmoid junction and it is completed when the margin of the sigmoid sinus is exposed. Therefore, the final landmark of craniectomy of the subasterional approach is not exactly the asterion, but the margin of the transverse-sigmoid junction. Venous bleeding from the diploic vein, the epidural space and/or the mastoid emissary vein occurred consistently during high-speed drilling but is controlled easily using bone wax. Such hemostasis technique is indispensable for this approach (Figure 2) [15].

2.4. Dura Opening and Intradural Exposure

After the craniectomy, the dura is exposed and opened under the microscope in two possible ways. Or the dura is cut as an anteriorly based semicircular U-shaped flap, with a wide base toward the sigmoid sinus [7, 2]; this semilunar incision starts from the level of the jugular bulb and ends at the level of transverse sinus; it must be parallel and almost 1 mm posterior to the sinuses [29]. Or the dura could be also opened in a cruciate fashion and the flaps held aside with suture [30]. At the end of incisions, dura mater could be hanged anteriorly to the skin flap with sutures and stay sutures are placed on the dural edge to enhance exposure [1, 29]. The idea of making additional cuttings appears to be not necessary; furthermore, this will facilitate dura closure afterwards, at the end of surgical approach (Figure 3) [31]. When the dura cut is done, the posterior fossa dura maintains its position on the moist surface of the cerebellum, and a wet cottonoid is placed on the top of the dura to prevent drying. After its placement, it's necessary to perform intermittent irrigation of the cottonoid and the dura; this procedure ensures to avoid the desiccation of tissues [1].

CSF Drainage Maneuvers

Neurosurgery experience showed that an important maneuver in retrosigmoid approached surgery is a sufficient drainage of CSF. After anesthesia is induced, it is appropriate to perform a CSF drain because this procedure helps minimize the retraction on the cerebellum, averts a postoperative CSF leak, decreases the pressure of the posterior fossa and facilitates the access to the lesion [7, 32]. However, in some patients, it appears to be difficult to drain the CSF because of the possibility that a fulminant cerebellar swelling may occur after the dura mater incision; in addition, when an excessive cerebellar retraction for drainage of CSF is attempted, an unexpected cerebellar injury could be induced. Method usually used to obtain an operative corridor into the posterior fossa consists in opening the lateral cerebellomedullary cistern or the lateral cerebellopontine cistern, or cistern magna (that now results obsolete) [32]. Anyway, in alternative the placement of a lumbar drain could be a valid tool, indeed, before opening the dura mater, the lumbar drainage is opened to drain 20 to 30 cc of CSF, that is sufficient for cerebellum relaxation, than it could closed and again opened as the surgery may require [7].

Figure 3. Intradural view and surgical approaches to posterior fossa. A. Lower exposure during retrosigmoid approach: intradural microsurgical view of the lower neurovascular complex. B. Upper view of an adult cranial fossa. The different surgical routes to the posterior fossa are shown. Yellow rectangle: Supratemporal approach-upper neurovascular complex; Green rectangle: Retrosigmoid approach- middle neurovascular complex; Light blue triangle: Lower retrosigmoid or Far lateral approach-lower neurovascular complex.

Cerebellar Retractors Placement

Retractors allow neurosurgeons to work within confined spaces, unhindered by an assistant's hand, by applying a constant force to reposition structures that would otherwise impinge on the operative line of sight [33]. However, because retractor-induced tissue edema and injury remain sources of neurosurgical morbidity, the utility of fixed retraction comes at a price; furthermore, fixed retractors require time to adjust and readjust repeatedly as the exposure demands [29].

In retrosigmoid approach, retraction of the cerebellum through retractors is seldom necessary.

The benefit of its usage is in order to obtain an adequate surgical exposure, that allows the surgeon to visualize the extremely important structures in the CP angle. In particular, the direction of the application of brain spatulas for surgery admit to see different parts in the various compartments of the CP angle. Positioning retractors laterally permits to have an exposure of the middle neurovascular complex; it could be used for a lesion in the midportion of the CP angle, such as a vestibular schwannoma. Positioning retractors from top-down permits to have an exposure of the upper neurovascular complex, parallel to the superior petrosal sinus; it could be used for a microvascular decompression operation for trigeminal

neuralgia. Positioning retractors from bottom-up permits to have an exposure of the lower neurovascular complex; it could be used in hemifacial spasm, because the facial nerve root exit zone is located only a few millimeters above the glossopharyngeal nerve and the PICA is commonly a compressing vessel [3]. However, in the vestibular schwannoma surgery through posterior fossa, cerebellar retraction is usually maintained for several hours, and this could provoke a cerebellar injury [29].

Because of the need to find a safe and effective solution to avoid the possibility of injury due to its utilization, now cerebellar retractors are not required in posterior fossa approaches because of refinements of the surgical and neuroanesthesia [29]. Indeed, when adequate conditions such as patient positioning, adequate anesthesia techniques, and surgical manipulations are applied in posterior fossa approach (except for neurovascular decompression and some of the acoustic neuroma surgeries), cerebellar retractors are not needed [29]. For example, a surgical manipulation, in which their usage is not required, consists in suturing the dura anteriorly over the sigmoid sinus because this maneuver could allow the maximal anterior exposure [1]. Moreover, another option is to insert a spatulum fixed by a Leyla-retractor and gain insight to the CP angle to hold (not retract!) the cerebellum [31].

2.5. Tumor Exposure and Removal

In the first moments of the dissection, when it is easiest to distinguish tumor from surrounding tissues, arachnoid adhesions are released and the cerebellum and lower cranial nerves are separated from the tumor. Once the cranial nerves have been identified, the tumor is morcellized from its core through ultrasonic aspiration, which is especially helpful when resecting the core of the tumor because it allows the removal of its smaller fragments. An important procedure during tumor removal is the monitoring of the facial nerve. If there are some evidence of its irritation, the surgeon should think about changing the area of dissection; in facts, after the facial nerve identification, it is important to perform a dissection of it from the tumor with a round knife. The facial nerve is usually displaced anteriorly against the anterior rim of the internal auditory canal, and this spot is most susceptible to injury during dissection [7]. After brain tumor removal, hemostasis could be performed using hemostat such as TachoSil, a sponge with an active yellow side coated with human thrombin and human fibrinogen. Its effect can be enhanced and supported by an autologous fibrin sealant to cover the surgical bed and to achieve dural closure, repair of dural defects, and to fill “dead spaces” with the same product [34, 35]. The microscopical approach may gain some advantages from the endoscopic technique. The application of neuroendoscopy will likely reflect less-invasive alternatives of traditional skull base approaches and may enhance the surgical view along deep or tight corridors not well visualized with the binocular microscopic view [36].

2.6. Closure Techniques

Once tumor removal is complete and hemostasis is obtained, the tack-up dural sutures applied during the dural opening phase are cut and the dura could be closed with 4-0 woven

nylon suture; in order to guarantee a major stability, a patch of blood-impregnated microfibrillar collagen hemostat is layered on top of the dural closure filling the craniectomy defect [7, 1]. Another way to make duroplasty is using the autologous pericranium graft, inserting it through the defect as an underlay hourglass-shaped plug. For obtaining this, the graft harvested has to be slightly larger than the dural defect, in order to have its edges under the dural plane and then it is fixed under operative microscope magnification with separated stitches (with an “inside-to-outside” direction) to the dura mater, using a 3-0 running silk. After that, the inserted patch was augmented with one layer of absorbable hemostats, with small pieces of surgical patches and with dural sealant [34]. In consideration of the thinness and fragility of pericranium in some population, like children, it could be another option to use ligamentum nuchae as graft; it could be more robust than pericranium, but this statement needs to be considered with caution and the understanding that this may not be true for all age groups [38]. When the duroplasty is complete, the bony defect could be filled with different materials, that reduce the risk of postoperative headache, such as: acrylic muscle, fibrin glue, wax or polymethyl methacrylate (PMMA). The muscles are then closed in layers primarily using their respective fascial planes with interrupted 2-0 woven polyglactic acid suture [1]. During closure, the aponeurotic fascia that was dissected before, could be an extra layer that helps to achieve a more hermetic closure [7, 39, 40]. The deep layer of the skin is closed with inverted, interrupted sutures, in which the staples are used to approximate the skin. Antibiotic ointment is applied to the staples and a 5x 3x 7cm island-type dressing is placed over the staple line; since this is not a pressure dressing, it can be removed the day after surgery [1].

ABSTRACT

Facial nerve (FN) palsy represents the most frequent complication of VS surgery, therefore all of the professionals involved in the treatment of VS should be aware of its implications and treatment. Several treatments have been described for the management of facial nerve paralysis. The choice of the repair technique depends on various factors, including the type and site of lesion, the time elapsed from the injurious event, the patient's expectations and the rehabilitation. Post-operative facial nerve paralysis can be treated with static and dynamic techniques.

Static techniques are based on the passive correction of muscle deficits without restoring their movement, while dynamic techniques aim to restore the active function of the affected mimic muscles, through the restoration of the muscular innervation or their replacement with free or pedunculated muscle flaps.

INTRODUCTION

Vestibular Schwannoma (VS) is one of the most difficult brain tumours to remove. They account for the 85-92% of cerebellopontine angle tumours, 93.1% of intracranial nerve Schwann cell tumour and 7.79-19.64%, of intracranial tumours [1].

Over the past 25 years VS surgery has undergone immense changes and the progressive improvement of surgical instruments and techniques have drastically reduced the mortality rate [2].

The focus of the surgery has passed from the preservation of “life” to the preservation of “quality of life” with more attention to the preservation of the cranial nerves function.

Facial nerve (FN) palsy represents the most frequent complication of VS surgery, therefore all of the professionals involved in the treatment of VS should be aware of its implications and treatment [3].

The effect of FN palsy are both clinical and psychological. From a clinical point of view facial palsy induces oral incompetence, collapse of the nasal valve, dysfunctional lacrimation up to possible serious ophthalmic complications like corneal ulceration [4] while the loss of facial expression and the alteration of the muscular tone and movements reduce significantly the quality of life of these patients [5].

The treatment of VS has changed in the last 20 years; small tumours are managed conservatively, while surgery is reserved for medium-large sized VS and radiologically growing tumours [6].

In VS surgery the facial nerve is at high risk of lesion due to its intimate relationship with the tumour. The introduction of the operating microscope by William House [7] and the use of facial nerve neurophysiological monitoring [8] has considerably decreased the incidence of postoperative facial palsy [6, 9].

However, facial nerve outcome after VS surgery is influenced by several factors and the size of the tumours represents the most important one [1, 10]. Additional factors that can influence the prognosis of FN function have been reported, such as the patient’s age and comorbidities, the extent of tumour removal (complete vs partial removal), the gross anatomy of the tumour (cystic vs non cystic form) [10].

CLASSIFICATION AND TREATMENT

Several classifications have been proposed to categorize facial nerve function such as the FaCE Scale [11], the Facial Disability Index [FDI] [12], Sunnybrook’s staging system [13]; still, the most utilized classification is the House-Brackmann grading system [14].

In 2003 Kanzaki et al. [15] proposed a modification of the HB scale for reporting facial nerve outcome after VS surgery (Table 1).

Table 1. Kanzaki et al. Tokyo classification

Grade I		Normal facial function in all areas
Grade II	Gross:-	Slight weakness noticeable on close inspection
	Synkinesis*	Very slight-noticeable on close inspection when the mouth is protruded forcibly
	At rest:-	Normal symmetry and tone
	Motions:	a) Forehead: Moderate to good function
		b) Eye: complete closure with minimal effort
		c) Mouth: Slight asymmetry
Grade III A	Gross:-	Obvious but not disfiguring difference between the two sides.
	Synkinesis*	<i>Slight</i> noticeable but not complete when the mouth protruded forcibly. Some contracture and/or hemifacial spasm may be present.
	At rest:-	Normal symmetry and tone
	Motions:	a) Forehead: slight to moderate movements
		b) Eye: complete closure with effort <i>eye comfortable and in good condition with or without lubricants</i>
		c) Mouth: Weak with maximum effort

Grade I		Normal facial function in all areas
Grade III B	Gross:-	Obvious but not disfiguring difference between the two sides.
	Synkinesis*	<i>Moderate</i> eye close completely when the mouth is protruded forcibly some contracture and/or hemifacial spasm may be present
	At rest:-	Normal symmetry and tone
	Motions:	a) Forehead: slight to moderate movements
		b) Eye: complete closure with effort <i>eye dry and uncomfortable with evidence of exposure keratitis requiring lubricants and possibly tarsorrhaphy</i>
		c) Mouth: Weak with maximum effort
Grade IV	Gross:-	Obvious weakness and disfiguring asymmetry
	Synkinesis*	<i>Severe</i> - Apparent mass motion whilst speaking
	At rest:-	Normal symmetry and tone
	Motions:	a) Forehead: None
		b) Eye: incomplete closure
		c) Mouth: Asymmetry with maximum effort
Grade V	Gross:-	Barely perceptible or no motion
	At rest:-	Asymmetry
	Motions:	a) Forehead: none
		b) Eye: none or incomplete closure
		c) Mouth: Slight or no movement
Grade VI		No movement. No tone.

* Synkinesis can be assessed by observed the degree of the eye closure when the mouth moves or by forcible protrusion of the lips. Synkinesis may include contracture and/or hemifacial spasm.

Several treatments have been described for the management of facial nerve paralysis. The choice of the repair technique depends on various factors, including the type and site of lesion, the time elapsed from the injurious event, the patient's expectations and the rehabilitation possibilities [16].

Facial Nerve paralysis after VS surgery can immediate or delayed.

- Immediate paralysis is related to intraoperative trauma of the nerve. In case the nerve is intact and responds to intraoperative electrical stimulation, a post-operative palsy is treated with post-operative steroids (e.g., dexamethasone i. v. at 4 mg every 6 hours during 48 hours).

In cases of intraoperative interruption of the nerve, immediate reconstruction gives the best long term results [17] (see below).

- Occasionally a *delayed paralysis* can present several days after the surgery. High-dose of steroids are indicated and recovery is possible in most cases [18].

Facial Nerve Repair Techniques

- Intraoperative repair

In case of intraoperative interruption of the nerve immediate reconstruction is indicated, being direct end-to-end anastomosis the preferred technique [18].

- Direct end-to-end anastomosis (or primary neurorrhaphy)

Direct end-to-end anastomosis (or primary neurorrhaphy) is considered the best option in case of acute post-traumatic facial nerve palsy in terms of recovery outcomes [19, 20].

After the removal of the VS, nerve stumps are identified and brought together. It is essential to avoid any tension between the two nerve stumps (proximal and distal), and to have a sufficient and useful contact between the endoneural surfaces. No difference has been shown between epineural and fascicular repair in terms of functional result in case of monofascicular nerve stumps. In polyfascicular nerve stumps, an interfascicular repair secures an optimal alignment of the nerve ends. Nerve repair is carried out using non-resorbable 8-10/0 suture.

To avoid tension between the two stumps in translabyrinthine surgery it is possible to free the second and third portion of the nerve from its bony channel and reroute it in the cerebellopontine angle where the two stumps are anastomosed. Since direct suturing, especially in the cerebello-pontine angle, is most of the time difficult, fibrin glue and temporalis fascia can be used instead of sutures [21].

- Interposition nerve grafts

When the nerve anastomosis cannot be performed without tension or there is a nerve gap, an interposition (or cable) nerve graft is used.

The sural nerve, the great auricular nerve or the medial antebrachial cutaneous nerve are the most common donor sites of nerve grafts because they are long, unbranched and they are not associated with critical sensory deficit. Both sides of the nerve graft is co-opted in an end-to-end fashion to the ends of the two stumps. Also in this case the fibrin glue and fascia are used instead of sutures.

Immediate repair of the facial nerve leads to HB grade 3 in most of the cases [22].

POST-OPERATIVE FACIAL NERVE REHABILITATION

Post-operative facial nerve paralysis can be treated with static and dynamic techniques.

Static techniques are based on the passive correction of muscle deficits without restoring their movement, while dynamic techniques aim to restore the active function of the affected mimic muscles, through the restoration of the muscular innervation or their replacement with free or pedunculated muscle flaps.

Static Reanimation

Static reanimation is used to achieve symmetry or a slightly overcorrection at rest on the normal side without providing animation. Static procedures are a good option for repairing specific cosmetic or functional deficits of the peri-orbital, perioral and to address nasal obstruction due to nasal valve collapse [22].

Although dynamic reanimation should be the gold standard, in a subset of patients, static techniques may be more appropriate. For patients with significant comorbidities, a shortened life span, advanced age, patients who are not good candidates for prolonged general anaesthesia, or in whom free muscle transfer may not be appropriate, static correction can still provide improved symmetry and function [23].

Rehabilitating the eye is one of the most important immediate needs in facial paralysis. Paralytic lower eyelid ectropion/retraction and lack of upper eyelid closure contribute to lagophthalmos and lacrimal dysfunction. A gold or platinum weight can be placed in a submuscular pocket along the superior margin of the tarsal plate (Figure 1). Other techniques to improve the paralyzed eye include tarsorrhaphy, lateral canthopexy; a modification of a tarsoconjunctival flap has also been described to repair ectropion and lagophthalmos [24, 25].

Functional deficits related to midface flaccidity include external nasal valve collapse and nasal obstruction, and lip ptosis with associated drooling and speech difficulty. The entire midface cheek complex also becomes ptotic and displaced inferiorly exacerbating lower eyelid and lip ptosis.

Figure 1. Gold weight. Note the gold weight on the upper eyelid, placed at a submuscular pocket along the superior margin of the tarsal plate.

Static suspension with slings can be used. Slings can be made of fascia (tensor fascia latae), tendon (palmaris longus) or prosthetic material such as Gore-Tex®. The graft is attached to the temporal fascia or to the zygoma. Midface subperiosteal lifts may also be beneficial.

Dynamic Reanimation

The aims of a dynamic procedure are to restore voluntary movement, especially the smile, resting tone and facial symmetry.

Reconstructive modalities for facial paralysis can be classified by two basic criteria: the first is whether the reconstruction is based on the facial nerve or on a different cranial nerve and the second is whether the working muscle unit is the original facial musculature or a transferred muscle flap.

Reanimation based on the facial nerve can be on the ipsilateral or contralateral nerve depending on the presence of a functional and usable branch or stump. The duration of paralysis is the determinant for the need for muscle transfer or transplant: if it is less than 12 months, the facial musculature is assumed to be able to be reinnervated. Muscles become irreversibly atrophic by 24 months, in which case muscle replacement is indicated. Even if surgical techniques for dynamic nervous resuscitation have been improved in the recent years, it is still very difficult to obtain an House Brackmann grade better than grade 3 [26].

Reinnervation

The aim of reinnervation procedures is to re-establish the input to facial nerve stumps using donors other than the native facial nerve. This procedure is useful when the proximal stump of the nerve is no longer available for example in very large tumours with distorted anatomy.

Figure 2. Hypoglossal-to-facial nerve transfer (post-operative result). A HB grade III is achieved (note the complete closure of the right eye) at 12 months of follow up.

Hypoglossal (XII) - to - Facial (VII) Nerve Transfer

The VII nerve is identified at the stylomastoid foramen and transected, while the XII nerve is divided distally, reflected upward and sutured with the VII nerve. Alternatively the XII nerve is partially divided in order to avoid tongue atrophy and a great auricular nerve “jump graft” can be coopted between the XII and the VII nerve. In this case an end-to-side anastomosis is performed, although a tongue dysfunction may occur in the 25% of the patients and the transfer may lead to an unnatural appearing activation of the intact facial musculature [27, 28].

After 12-months an HB grade 3 with synkinesis can be achieved (Figure 2).

Masseter to Facial Nerve Transfer

Masseterine nerve (or the masseteric branch of the trigeminal nerve) has become most recently a good donor site to innervate facial musculature because of its anatomic location, relative easy dissection and the facial nerve results [4, 29, 30].

VII-VII Cross Facial Nerve Grafting (CFNG)

The CFNG technique uses branches of contralateral functioning facial nerve to innervate paralyzed muscles. A nerve graft (e.g., sural nerve graft) connects healthy peripheral nerve branches to corresponding branches of specific muscle groups on paralyzed sides. CFNG can be performed as one stage or two-stages procedure. In the first stage the selectively neurectomized branches of the unaffected facial nerve provide motor fibers through CFNGs; after 9-12 months and after electrophysiological confirmation, secondary microcoaptation takes place with corresponding branches of the affected facial nerve. If denervation is longer than 6 months, a partial hypoglossal-to-facial nerve graft can be combined to CFNG two-stages procedure to prevent atrophy and loss of motor endplates ('babysitter' of the facial muscles, as described by Terzis [31]).

Local Muscle Transposition

Muscle transposition is performed when there is irreversible muscular atrophy and fibrosis, due to the long denervation period.

Temporalis Muscle Transfer

It is still considered the best choice for facial rehabilitation due to the greater excursion of movement and adaptability to orbit. The muscle with its fascial extensions can be transferred and sutured to eyelids, ala of nose, oral commissure, and upper and lower lips. Labbè et al. [32] described a lengthening myoplasty: the tendon is rerouted to the corner of the mouth and additional length is achieved by repositioning the muscle's origin on the skull.

Masseter Muscle Transfer

It is a valuable option for the rehabilitation of the buccal complex. It is possible to recover an acceptable smile, a raising of the upper lip and the buccal angle. The muscle is, indeed, released from the mandible and transposed to the orbicularis oris resulting in a lateral vector.

Digastric Muscle Transfer

The anterior digastric tendon is mobilized and inserted into orbicularis oris at inferior vermilion border. The technique can be applied in case of isolated mandibular branch palsy to restore lower lip depression function.

Microneurovascular Muscle Transposition

The microneurovascular muscle transfer is indicated in case of long-standing facial paralysis, when facial muscles cannot gain useful function after reinnervation. The main advantage of a free functional muscle transfer vs local muscle transfer is the possibility to control precisely the origin, insertion, tension and location of the muscle. The procedure can be performed in one stage if the motor nerve is directly sutured to a branch of the contralateral facial nerve. The functional improvement is visible within few months, avoiding nerve grafts and a second operation. Nevertheless, there is a lack of suitable muscle (long neurovascular bundle), except for children. The two stage procedure involves a CFNG before harvesting a free muscle flap.

The following muscles may be used as free functioning transfers:

- Gracilis muscle: it is considered the gold standard for rehabilitating the oral commissure [16, 33-35] (Figure 3)
- Pectoralis minor
- Latissimus dorsi muscle, that allows recovery of facial symmetry, muscle tone and expression similar to the traditional temporalis muscle transfer [36]
- Serratus anterior
- Rectus abdominis
- Rectus femoris
- Sartorius
- Abductor hallucis.

Figure 3. Free gracilis muscle transfer for smile restoration (intraoperative views). A. Harvest of free gracilis muscle flap. The photograph shows the dominant vascular pedicle (asterisk) and the gracilis motor nerve. Note the marker sutures placed at 1cm intervals, to insert the muscle at the in situ tension. B. Scheme of the free gracilis muscle flap inset. The muscle is transferred to the cheek pocket. The vascular pedicle is anastomosed to the facial vessels and the motor nerve coaptation is made to the masseteric nerve.

CONCLUSION

The aim of vestibular schwannoma surgery is total tumour removal with the preservation of the facial nerve integrity and minimal postoperative morbidity.

If a facial reanimation is necessary, immediate nerve repair yields the best outcomes.

If the denervation time is less than 12-18 months, facial muscle can be reinnervated through reinnervation procedures.

If the denervation is over 24 months, CFNGs are used for neurotization of free or pedicled vascularized muscle transfer for facial muscle substitution (Figure 4).

Figure 4. Facial reanimation treatment algorithm.

Revision and ancillary procedures along with early and long term follow up are essential to determine the functional and aesthetic outcome.

 acellular collagen matrix, 2565, 2566, 2569

- acellular dermal matrix, 2566, 2574, 2575, 2577, 2578, 2579, 2592, 2602, 2616, 2627, 3542, 3553
- acetaminophen, 2480, 2486, 2520, 2530, 2531, 2532, 2533, 2535, 2536, 2537, 2538, 2545, 2719, 3309, 3420, 3746, 3755, 3760, 3761, 3865, 3872, 4589, 4590, 4786, 5458, 6179, 6180, 6192, 6195, 6197, 6200, 7092, 7230, 7232, 7235, 7239, 7240
- acetyl-L-carnitine, 3791, 3798
- acid ceramidase, 3541, 3548, 3554
- acid-base imbalance, 3314, 3898
- acid-base, 559, 577, 711, 2801, 2826, 3027, 3097, 3276, 3313, 3314, 3316, 3317, 3318, 3323, 3324, 3325, 3326, 3328, 3329, 3332, 3333, 3335, 3526, 3623, 3626, 3644, 3702, 3825, 3898, 4528, 6008, 7278
- acidosis, 260, 2124, 2896, 3025, 3099, 3110, 3314, 3317, 3320, 3323, 3324, 3325, 3326, 3327, 3328, 3329, 3333, 3418, 3527, 3783, 3792
- acidosis, 3816, 3859, 4018, 4785, 4976, 5612, 7290
- active components, 3451, 3454, 3458, 7194
- actively engaged, 6925
- active-passive function, 3452, 3453, 3454
- activities of daily living, 924, 1035, 1036, 1040, 1041, 1042, 1052, 1058, 1872, 2025, 3907, 4051, 4345, 5579, 5882, 6230, 6245, 6924, 7041, 7251
- acupuncture, 2533, 2539, 3163, 3164, 3165, 4521, 5609, 5610, 5611, 5612, 5613, 5614, 5615, 5616
- acute aortic dissection, 5442, 5443, 5448, 6552
- acute artery occlusion, 4723, 4725
- acute complications, 776, 784, 785, 2035, 2055, 2077
- acute experiments, 3431
- acute hydrocephalus, 927, 931, 932, 937, 938, 942, 943, 944, 958, 1019, 3802, 3861, 3862, 3863
- acute limb ischemia, 3701, 4726, 4748, 4826, 4833, 4872, 4877, 4878, 4881, 4889, 4924, 4992
- acute liver failure, 2866, 2878, 2880, 2882, 2886, 3641, 3750, 3751, 3752, 3754, 3755, 3756, 3759, 3760, 3761, 3763, 3774, 3865, 3872, 3873, 6622
- acute mesenteric ischemia, 3666, 3683, 3684, 3713, 3718, 4727, 4839, 4840, 5008
- acute myocardial infarction, 3104, 3342, 3698, 3699, 3705, 4978, 5007, 5442, 5446, 6423, 7225
- acute pancreatitis, 1237, 1238, 1239, 1240, 1241, 1242, 1285, 1288, 1970, 2892, 2893, 2894, 2895, 2896, 2904, 2905, 2906, 2907, 2909, 2910, 2911, 2912, 2913, 3112, 3681, 3705, 3920, 4996, 5457, 5458, 5461, 6298
- acute respiratory distress syndrome, 2796, 3666, 3675, 3716, 3844, 3845, 3922, 4038, 4629, 4713, 4812, 4836, 4976, 4979, 5007, 5457, 5458, 5936, 7157, 7165
- acute-phase reactants, 4503, 7255, 7257, 7258, 7260, 7261
- Adamkiewicz artery, 4781
- adaptation, 236, 239, 240, 241, 248, 741, 870, 871, 872, 874, 875, 883, 985, 1493, 1603, 1672, 1675, 1743, 1947, 2123, 2147, 2156, 2168, 2186, 2731, 2817, 2912, 2967, 3100, 3280, 3304, 3310, 3450, 3675, 4382, 5009, 5275, 6018, 6090, 6126, 6188, 6331, 6332, 6391, 6578, 6702, 6728, 6799, 6936, 6988, 7018, 7301
- adenocarcinoma, 712, 1104, 1257, 1262, 1263, 1266, 1267, 1268, 1269, 1271, 1272, 1274, 1275, 1276, 1277, 1282, 1284, 1291, 1292, 1314, 1316, 1317, 1318, 1330, 1334, 1337, 1338, 1634, 1885, 1886, 1901, 2329, 2343, 2443, 2451, 2906, 2969, 2971, 3152, 3350, 4159, 4288, 4407, 4412, 4436, 4489, 4689, 5558, 5804, 5833, 5834, 5842, 5843, 5844, 5845, 5846, 5847, 5944, 5947, 5948, 5962, 6020, 6078, 6079, 6080, 6081, 6084, 6085, 6086, 6324, 6871, 6873, 6879
- adenoid hypertrophy, 1536, 1681, 1683, 1686
- adenoidectomy, 1460, 1535, 1536, 1554, 1555, 1683, 1686, 1687, 1702, 2461, 2463, 2464, 2466, 2469, 2472, 2473, 2483, 2484, 2485, 2487, 2488, 2489, 2492, 2493, 2496, 2499, 2507, 2508, 2509, 2510, 2514, 2515, 2516, 2523, 2524, 2527, 2529, 2530, 2531, 2536, 2539, 2540, 2543, 2546, 2549, 7087
- adenoids, 1533, 1534, 1683, 1687, 2495, 2515
- adenoma, 1104, 1193, 1194, 1196, 1198, 1199, 1200, 1201, 1203, 1204, 1205, 1210, 1212, 1213, 1219, 1251, 1475, 2418, 3321, 3746, 4322, 5641, 5642, 5643, 5646, 5647, 5648, 5649, 5650, 5651, 5652, 5676, 5688, 5773, 6090, 6094, 6099, 6100, 6101, 6114, 6115, 6116, 6120, 6130, 6132, 6907, 7052, 7053, 7056
- adenomatous polyps, 1332, 1895
- adhesion, 8, 10, 70, 75, 166, 167, 180, 374, 397, 897, 906, 938, 984, 1433, 1565, 1593, 1732, 2367, 2368, 2371, 2489, 2802, 2826, 2954, 2965, 2997, 3011, 3017, 3047, 3070, 3075, 3076, 3088, 3097, 3099, 3106, 3107, 3108, 3110, 3177, 3341, 3374, 3490, 3496, 3507, 3572, 3655, 3680, 4105, 4487, 4691, 4692, 4702, 4703, 4710, 4712, 4955, 4956, 5153, 5572, 5576, 5607, 5744, 5956, 5969, 6205, 6279, 6510, 6651, 6688, 6689, 6690, 6694, 6707, 6708, 6709, 6791, 7261, 7325
- adhesive vein ablation, 4934
- adipocyte, 163, 165, 166, 167, 168, 175, 176, 177, 178, 179, 523, 526, 2152, 2158, 2160, 2170, 6977, 6978, 6980, 6986, 6987, 6988, 6992
- adipogenic, 3570, 6415, 6422, 6570, 6988
- adiponectin, 163, 167, 168, 170, 171, 172, 175, 179, 180, 184, 2114, 2131, 2145, 2152, 2158, 2159,

- 2162, 2163, 2170, 2171, 2172, 3709, 5353, 5354, 5361, 5395, 5397, 5423, 6699, 6702, 6978, 6980, 6983, 6984, 6990, 7202, 7208
- adipose-derived stem cells, 2561, 2562, 2563, 3443, 3538, 3555, 6411, 6412, 6423, 6424, 6425, 6426, 6427, 6429, 6430
- adjustable banded RYGB, 801
- adjustable gastric band, 138, 151, 154, 157, 158, 159, 160, 168, 169, 170, 173, 174, 181, 182, 183, 184, 189, 191, 197, 200, 206, 222, 237, 245, 250, 256, 257, 258, 260, 769, 795, 796, 799, 800, 808, 809, 812, 818, 840, 869, 874, 875, 1565, 2134, 2163, 2174, 2184, 2185, 2680, 2681, 2714, 2722, 2832, 4550, 4583, 5015, 5045, 5344, 5360, 5384, 6355, 6356, 6360, 6367, 6397, 6979, 6981, 6982, 6989, 7005, 7006, 7010, 7011, 7014, 7019, 7028, 7169, 7170, 7174, 7252, 7253
- adjustable gastric banding, 157, 158, 159, 160, 168, 170, 173, 181, 182, 183, 184, 197, 200, 206, 222, 237, 245, 250, 256, 795, 796, 799, 808, 809, 818, 840, 869, 874, 875, 1565, 2163, 2174, 2184, 2185, 2680, 2681, 2722, 2832, 4583, 5015, 5045, 5344, 5360, 5384, 6356, 6360, 6367, 6397, 6979, 6982, 6989, 7005, 7006, 7010, 7014, 7019, 7028, 7169, 7170, 7174, 7252, 7253
- adjuvant analgesics, 7237, 7239
- adjuvants, 3120, 3200, 4587, 4588, 4589, 4590, 4593, 7229, 7237, 7238, 7239, 7240
- adrenal lesion angiography, 1208
- adrenal lesion CT, 1208
- adrenal lesion imaging, 1208
- adrenal lesion MRI, 1208
- adrenal lesion nuclear imaging, 1208
- adrenal lesion US, 1208
- adrenal, 688, 696, 1207, 1208, 1209, 1210, 1211, 1212, 1213, 1214, 1215, 1218, 1219, 1220, 1221, 1222, 1286, 1325, 1336, 1352, 1528, 1589, 1590, 1599, 1600, 1603, 1604, 1605, 1607, 1608, 2763, 3323, 3425, 3650, 3895, 4318, 4319, 5641, 5642, 5643, 5645, 5647, 5648, 5649, 5650, 5651, 5652, 5762, 5764, 5951, 5983, 6046, 6047, 7211, 7218
- ADS (acronym of author's name) palpebral area, 6436
- advancement of genioglossus, 1535
- adverse events, 215, 408, 500, 508, 532, 538, 549, 553, 563, 564, 565, 566, 567, 571, 578, 619, 626, 1450, 1460, 1464, 1469, 1470, 1662, 1688, 1952, 2005, 2024, 2035, 2044, 2091, 2531, 3899, 4051, 4523, 4524, 4588, 4655, 4659, 4691, 4705, 4888, 5382, 5468, 5919, 6017, 6069, 6072, 6102, 6171, 6172, 6183, 6474, 6487, 6493, 7238, 7298, 7300
- aerocele, 4012
- Afghanistan, 3990, 4012, 4014, 4015, 4023, 4032, 4033, 4037, 4041, 4042, 4929
- agarose, 707, 2954, 3541, 3728
- aggrecan, 3540, 3541, 3549, 4807
- aggrecanase, 3543, 3547
- aggregation, 948, 982, 983, 984, 989, 1076, 1519, 1851, 2637, 2801, 2802, 2821, 2826, 2995, 3076, 3077, 3079, 3080, 3081, 3084, 3095, 3096, 3098, 3099, 3100, 3101, 3102, 3108, 4674, 4818, 4887, 4955, 4956, 5468, 5930, 6482, 6715, 7086
- AHA/ASA, 3933, 3945
- airway obstruction, 214, 218, 424, 426, 433, 449, 1309, 1448, 1476, 1874, 1875, 1877, 1908, 2392, 2495, 2500, 3402, 3890, 3893, 4453, 4588, 5504, 5543, 5545, 6217, 6219, 7238, 7244
- alar batten graft, 438, 441, 449, 5485, 5499, 5500, 5502
- alcian blue, 3541
- alginate beads, 3541
- alimentary limb, 782, 783, 784, 785, 788, 822, 823, 826, 828, 829, 835, 839, 849, 851, 871, 873, 1866, 1996, 2000, 2003, 2733, 2832, 4579, 4604, 4609, 5097, 5098, 5107, 5124, 5125, 5126, 5127, 5129, 5133, 5147, 5148, 5150, 5156, 5157, 5158, 5159, 5217, 5219, 5220, 5229, 5234, 5235, 5236, 5238, 5243, 5244, 5246, 5369, 5390, 6356
- allogeneic, 351, 1695, 1696, 1734, 1744, 2633, 2917, 2923, 2924, 2934, 2935, 2936, 2984, 3000, 3001, 3263, 3264, 3268, 3269, 3292, 3294, 3297, 3300, 3440, 3543, 3544, 3588, 3600, 3602, 3609, 3639, 3649, 3652, 3654, 3655, 3659, 3660, 3664, 3721, 3722, 3727, 3728, 3729, 3730, 3731, 3739, 3740, 3757, 5911, 6472
- allotransplantation, 2928, 2936, 3349, 3372, 3441, 3606, 3640, 3647, 3648, 3653, 3655, 3656, 3657, 3658, 3661, 3662, 3663, 3664, 3712, 3731
- alpha lipoic acid, 7117, 7120, 7121, 7123, 7125
- ALS/ALG/ATG, 3652
- alterations of the lamina cribrosa, 6886
- altered anatomy, 146, 813, 1200, 1841, 1948, 2001, 2005, 2016, 7023
- alveolar recruitment maneuvers, 7159
- alveolar recruitment, 7158, 7159, 7161, 7164
- Amadeus® system, 695
- ambulatory selective vein ablation under local anesthesia, 4964
- ambulatory, 215, 218, 256, 626, 1308, 1309, 1429, 1430, 1434, 1435, 1436, 1438, 1439, 1443, 1444, 1445, 1446, 1447, 1448, 1449, 1450, 1451, 1453, 1454, 1455, 1456, 1457, 1458, 1459, 1460, 1461, 1462, 1463, 1464, 1465, 1466, 1467, 1468, 1469, 1470, 1471, 1472, 1554, 1595, 1761, 1775, 1777, 1789, 1790, 1791, 1792, 1793, 1794, 1803, 1809,

- 1819, 1825, 1828, 1896, 2046, 2297, 2492, 2523, 2524, 2527, 2529, 2535, 2536, 2539, 2544, 2545, 2549, 2558, 2727, 2845, 3388, 3406, 3409, 3419, 4369, 4389, 4524, 4579, 4887, 4964, 4973, 5299, 5512, 5871, 5872, 5874, 5878, 5880, 6262, 6867, 7054, 7093
- ameloblastoma, 1698, 1707

- anatomic landmark-based registration, 665
- anatomic resection, 2333, 2334, 2335, 2343, 2345, 2346, 2353, 2354, 2356, 2358
- anatomical resection, 2334, 2339, 2341, 2353, 2358, 2359, 2364, 2368, 2371, 2880, 6076
- anesthetists, 5204, 6454
- aneurysm of the abdominal aorta, 4728, 4827, 4830, 4834, 4844
- aneurysm of the descending aorta, 4790
- aneurysm rerupture, 931
- aneurysm rupture risk, 4828
- aneurysm surgery, 882, 924, 957, 958, 960, 961, 962, 963, 964, 965, 995, 1061, 1663, 3179, 4760, 5010
- aneurysms of splanchnic arteries, 4812, 4843, 4844
- aneurysms of superior mesenteric, 4844
- angio-embolization, 1698, 2068, 2069
- angiogenic factors, 2996, 3560, 3566, 3568, 3570
- angioplasty, 985, 1001, 1004, 1010, 1012, 1014, 1016, 1017, 1410, 3699, 4037, 4038, 4211, 4723, 4741, 4789, 4790, 4813, 4820, 4841, 4843, 4850, 4856, 4863, 4865, 4869, 4872, 4873, 4875, 4886, 4892, 4894, 4904, 4908, 4918, 4934, 4940, 4948, 4969, 4970, 4971, 4978, 4992, 4994, 5007, 6596, 6602, 7074
- animal models of SAH, 1069
- anion gap, 3324, 3325, 3326, 3333
- annulus fibrosus, 2986, 3007, 3539, 3551
- antagonists, 221, 222, 881, 974, 984, 987, 988, 1030, 1452, 1891, 1895, 2655, 2921, 3036, 3274, 3298, 3547, 3651, 3710, 3712, 3793, 4515, 4516, 4517, 4518, 4519, 4521, 4522, 4525, 4563, 4565, 4572, 4589, 4978, 5397, 6197, 6587, 6588, 6589, 6591, 6600, 6605, 7087, 7088, 7241
- antecolic, 140, 839, 2000, 2001, 2003, 2737, 4300, 4604, 4606, 4607, 4609, 4610, 5085, 5094, 5164, 5173, 5221, 5245, 5246, 7005
- anterior cruciate ligament, 23, 24, 27, 1466, 1468, 2252, 3358, 3542, 6252
- anterior fusion, 5577, 5578, 5579
- anterior right mini-thoracotomy, 6500, 6510, 6528, 6544
- anterior right thoracotomy, 6454, 6463, 6466, 6478, 6485, 6494, 6496, 6520
- anti-aging, 6411, 6412, 6416, 6417, 6422, 6427
- antibiotic prophylaxis, 451, 1862, 1868, 1930, 2033, 2036, 2040, 2041, 2042, 2046, 2048, 2049, 2050, 3384, 3419, 3615, 3616, 3956, 4031, 4390, 4499, 4501, 4502, 4503, 4641, 4643, 4644, 4645, 4654, 4658, 4686, 4702, 4990, 5086, 6260, 6261, 7259
- antibiotic solution, 584, 4501, 4679, 4688, 4690, 6959, 6962, 7255, 7257, 7260, 7261
- anticoagulant, 1043, 1446, 1465, 1923, 2033, 2656, 2757, 3101, 3862, 3902, 4886, 4900, 4924, 4978, 4980, 4991, 5000, 5465, 5913, 5929, 5930, 6027, 6999
- anticoagulation, 141, 952, 973, 1014, 1614, 1725, 1863, 1864, 1865, 1868, 1869, 2033, 2036, 2037, 2067, 2072, 2648, 2996, 3034, 3725, 3864, 3902, 4043, 4297, 4369, 4457, 4857, 4879, 4900, 4948, 4967, 4968, 5926, 5928, 6020, 6244, 6539, 6617, 6837, 6860, 6867, 6999

- antiemetics, 4511, 4514, 4515, 4516, 4517, 4519, 4520, 4521, 4522, 4524, 4558, 7088, 7241
- antimetabolites, 3650
- antimicrobial sutures, 4701, 4706
- antioxidant proteins, 3791, 6418
- antioxidants, 3029, 3033, 3522, 3785, 3791, 3798, 4629, 5355, 5371, 6416, 6419, 6991, 7120, 7121
- antiplatelet therapy, 951, 952, 958, 1864, 1869, 1873, 1923, 2037, 4211, 4856, 4871, 4887, 4888, 4900, 4961, 4978, 4991, 4999, 5912, 5916
- antiplatelet treatment, 945, 1864
- antiplatelet, 945, 951, 952, 958, 1864, 1865, 1869, 1873, 1923, 2033, 2037, 2067, 3862, 4083, 4211, 4818, 4826, 4856, 4871, 4887, 4888, 4900, 4924, 4961, 4978, 4991, 4999, 5912, 5913, 5915, 5916, 5917, 6590
- antireflux therapy, 5505, 5506, 5507, 5510
- antiseptic gargle, 2042
- antiseptic(s), 107, 584, 1430, 1431, 1911, 2042, 2046, 2047, 2052, 2237, 3177, 3194, 3196, 3626, 4390, 4612, 4634, 4635, 4647, 4648, 4650, 4652, 4663, 4666, 4672, 4673, 4674, 4676, 4677, 4678, 4680, 4681, 4684, 4685, 4687, 4691, 4701, 4702, 4703, 4709, 4710, 4711, 4712, 4717, 4718, 4719, 4990, 6255, 6556, 6790, 7259, 7261
- antithrombotic therapy, 1861, 1862, 1863, 1868, 5912
- anti-torsion suture, 2738
- antrochoanal polys, 1683
- aortic aneurysm, 1084, 1086, 1087, 1088, 1090, 1489, 1505, 3346, 3369, 3376, 3379, 3466, 3467, 3468, 3469, 3476, 3671, 3674, 3677, 3685, 3697, 3702, 3708, 3710, 4188, 4596, 4614, 4723, 4744, 4748, 4760, 4769, 4777, 4778, 4779, 4781, 4782, 4790, 4791, 4792, 4793, 4796, 4805, 4806, 4807, 4808, 4809, 4811, 4812, 4813, 4817, 4827, 4828, 4836, 4845, 4846, 4847, 4848, 4875, 4976, 4996, 5007, 5008, 5009, 5011, 5448, 5896, 5897, 5898, 5904, 5905, 5906, 5907, 5920, 6470, 6487, 6551, 6552, 6553, 6555, 6559, 6566, 6567, 6568, 6744, 6749, 6750, 6838, 6847, 7224, 7272
- aortic arch aneurysm, 4753, 4769, 4780, 4806
- aortic arch, 1174, 1296, 1479, 1481, 2847, 2854, 3385, 3464, 3686, 4753, 4754, 4755, 4756, 4757, 4758, 4759, 4760, 4761, 4762, 4763, 4765, 4767, 4768, 4769, 4770, 4771, 4772, 4774, 4775, 4776, 4777, 4778, 4779, 4780, 4781, 4782, 4784, 4787, 4788, 4790, 4791, 4796, 4797, 4801, 4803, 4806, 4855, 5441, 5442, 5443, 5894, 6488, 6489, 6555, 6564, 7273, 7274, 7298
- aortic banding, 2839, 2846, 2854
- aortic coarctation, 2845, 4759, 4781, 4782, 4787, 4788, 4789, 4795, 4799, 4805, 4809
- aortic development, 4754, 4782
- aortic dissection, 1101, 4203, 4753, 4760, 4765, 4766, 4770, 4777, 4779, 4781, 4792, 4793, 4794, 4795, 4806, 4808, 4809, 4839, 4878, 4918, 5441, 5442, 5443, 5444, 5445, 5448, 5881, 5886, 5897, 5899, 5900, 5903, 5904, 5905, 5907, 5936, 6493, 6553, 6555, 6720, 6723, 6766, 6782, 6846, 6848, 6853, 6854, 7274
- aortic surgery, 1881, 3686, 3700, 3707, 3714, 4762, 4777, 4779, 4825, 4826, 4827, 5007, 5011, 5882, 5912, 5913, 5919, 5920, 6474, 6551, 6552, 6553, 6566, 6568
- aortic valve replacement, 4621, 6453, 6457, 6461, 6471, 6472, 6473, 6474, 6479, 6485, 6494, 6499, 6507, 6508, 6509, 6515, 6516, 6517, 6519, 6520, 6524, 6525, 6526, 6527, 6528, 6533, 6535, 6536, 6538, 6545, 6546, 6547, 6548, 6549, 6561, 6566, 6567, 6568, 6750, 6751, 6753, 6788, 6795, 6829, 6843, 7079, 7271, 7272, 7273
- aortic valve surgery, 6453, 6471, 6472, 6473, 6474, 6475, 6479, 6481, 6483, 6485, 6486, 6487, 6488, 6489, 6490, 6491, 6492, 6496, 6507, 6508, 6510, 6516, 6520, 6524, 6525, 6532, 6541, 6543, 6717, 6837
- aortobifemoral bypass, 4811, 4813, 4822, 4823, 4824, 4825, 4826, 4988, 4990, 4995, 4996, 4998
- aortocaval fistula, 2839, 2840, 2859, 2863
- aortoiliac atherosclerosis, 4811, 4812, 4813, 4814, 4815, 4816, 4818, 4833, 6775
- aortoiliac endarterectomy, 4821, 4822, 4824
- aortoiliac occlusive disease, 4814, 4818, 4821, 4824, 4833, 4838, 4845
- AoX and CPB, 6538, 6541, 6543, 6545
- apixaban, 1864
- appetite-hormones, 2173
- aquaporin-4, 3767, 3770, 3776, 3779, 3841, 3849, 3854
- arbitrary Lagrangian-Eulerian, 3461
- area of scleral, 6434
- Argon laser trabeculoplasty, 6888, 6897
- ARTEMIS, 3131, 3156
- arterial reconstructions, 4721, 4723, 4739, 4813, 4818, 4833, 4846, 4884, 4916, 4981, 4984, 4988, 4990, 4991
- arterial spin labeling, 1162, 3337, 3357, 3807
- arteriovenous fistula, 895, 936, 1179, 1347, 1656, 1658, 1663, 3357, 3371, 3812, 4729, 4745, 4904, 4905, 4918, 4922, 4932, 4934, 4935, 4968, 4969, 4970, 5000, 5012
- arteriovenous malformation, 878, 908, 936, 940, 941, 963, 964, 965, 1066, 1067, 1179, 1180, 1183, 1351, 1609, 1653, 1654, 1656, 1662, 1663, 2562, 4738, 5892

- arthroplasty planning, 2275
- arthroplasty, 11, 12, 102, 709, 733, 1455, 1456, 1466, 1575, 1670, 2199, 2200, 2210, 2250, 2251, 2275, 2283, 2290, 2291, 2293, 2294, 2295, 2297, 2299, 2307, 2308, 2309, 2320, 2331, 2332, 2708, 2710, 2715, 2724, 3134, 3137, 3138, 3154, 3155, 3156, 3539, 4621, 4699, 5560, 5561, 5867, 5868, 5869, 5872, 5873, 5874, 5878, 5879, 5880, 6246, 6263, 6273, 6274, 6275, 6923, 6924, 6928, 6929, 7076
- arthroscopy, 732, 1457, 1458, 1466, 1467, 1470, 2210, 2218, 2221, 2225, 2237, 2246, 2247, 2249, 2250, 2251, 2257, 2259, 2262, 2264, 2267, 2268, 2272, 3149, 3435, 3554, 4621, 6251, 6252, 6253, 6254, 6256, 6257, 6258, 6259, 6260, 6261, 6262, 6710, 6929
- articular cartilage, 3538, 3552
- as non-human primates, 3611
- ascenda, 6955, 6956, 6957, 6958, 6959
- ascites, 1038, 1102, 1248, 1262, 1267, 1328, 1336, 1724, 1840, 1849, 1851, 1853, 1854, 1855, 1858, 1859, 1866, 1918, 1949, 1973, 1977, 1981, 2334, 2348, 2364, 2365, 2366, 2369, 2888, 2896, 2968, 2974, 2975, 2977, 3754, 3757, 3865, 3926, 4479, 4480, 4481, 4990, 5336, 5368, 5377, 5379, 5402, 5404, 6133, 6134, 6135, 6136, 6137, 6138, 6139, 6140, 6141, 6142, 6143, 6144, 6279, 6286, 6309, 6622, 6627, 6629, 6630, 6651, 6654, 6655, 6657, 6658, 6660, 6871
- aspirin, 412, 413, 947, 948, 950, 951, 952, 982, 984, 1010, 1516, 1519, 1614, 1683, 1864, 1869, 1873, 1923, 2033, 2037, 2074, 3203, 3309, 3422, 4818, 4856, 4867, 4900, 4956, 4968, 5912, 5913, 5916, 5918, 5933, 6180, 6192, 6243, 6244, 6248, 7086, 7093
- association between XFS and systemic vascular dysfunction, 6891
- atelectasis, 142, 214, 218, 1239, 2392, 2718, 2726, 2727, 2804, 3306, 3893, 3896, 4141, 4566, 4655, 4661, 4979, 6069, 6074, 6075, 6242, 6477, 6718, 6789, 6999, 7158, 7160
- atherosclerosis, 164, 166, 167, 168, 176, 177, 178, 420, 767, 2136, 2820, 3357, 3366, 3370, 3466, 3475, 3476, 3478, 3754, 3762, 4508, 4749, 4765, 4791, 4811, 4813, 4814, 4815, 4818, 4826, 4828, 4840, 4841, 4842, 4843, 4847, 4852, 4866, 4872, 4873, 4875, 4876, 4877, 4881, 4888, 4901, 4902, 4903, 4905, 4906, 4907, 4908, 4975, 4976, 4992, 4996, 5006, 5286, 5362, 5413, 5429, 5441, 5442, 5443, 5445, 5446, 5448, 5789, 5904, 5905, 6101, 6243, 6474, 6609, 6699, 6702, 6704, 6755, 6847, 7061, 7212, 7219, 7228, 7266
- atherosclerotic plaques, 3341, 4738, 4742, 4763, 4839, 4840, 4850
- atherothrombotic complications, 4981
- ATP synthase, 3782, 3783, 3789

- binder, 489, 553, 1510, 1943, 2025, 2026, 3403, 3776, 3926, 5994, 6179, 6180
- bioactive, 1, 10, 11, 25, 69, 71, 72, 73, 74, 75, 77, 78, 80, 84, 85, 86, 89, 90, 93, 99, 100, 223, 343, 346, 1730, 1732, 1745, 1751, 2155, 2324, 2325, 3541, 3562, 3566, 3572, 3578, 6224, 6364, 6416
- biochemical markers, 1210, 1769, 2798, 3565, 5351
- bioengineering, 70, 73, 2983, 3000, 3002, 3004, 3005, 3007, 3449, 3476, 3566, 6423
- biologic, 8, 69, 70, 73, 75, 134, 345, 1136, 1433, 1434, 2022, 2299, 2352, 2445, 2520, 2757, 3001, 3206, 3207, 3239, 3294, 3341, 3433, 4181, 4377, 4598, 4601, 4744, 5010, 5576, 5639, 5959, 5981, 5983, 6004, 6006, 6018, 6019, 6021, 6171, 6172, 6177, 6181, 6423, 6528, 6703, 6873, 7302
- biological factors, 345, 2175, 4490, 7132, 7135
- biomarkers, 986, 994, 998, 2351, 2361, 2822, 2827, 2940, 2963, 3046, 3070, 3215, 3235, 3352, 3354, 3406, 3429, 3435, 3488, 3494, 3495, 3505, 3511, 3549, 3563, 3573, 3662, 3674, 3814, 3836, 3864, 3986, 5261, 5264, 5331, 5333, 5335, 5340, 5341, 5347, 5352, 5353, 5354, 5355, 5651, 6039, 6364, 6702, 6705, 6991, 7207, 7225, 7226
- biomaterials, 70, 73, 76, 86, 88, 343, 346, 349, 351, 1433, 1436, 1729, 1731, 1734, 1746, 2425, 2965, 2966, 2984, 3001, 3002, 3003, 3004, 3005, 3006, 3349, 3365, 3402, 3444, 3546, 3552, 3560, 3563, 3566, 3572, 3574, 3737, 3738, 3740, 3741, 3742, 3743, 4072, 6413, 6423, 6424, 6992, 7125
- biomechanical testing, 308, 3557, 3565, 3570, 3573
- biopsychosocial, 2380, 6171, 6172, 6185
- bladder cancer, 695, 1353, 2724, 3143, 3154, 3432, 3444, 4345, 4347, 4350, 4360, 4361, 4362, 5424, 5428, 5429, 6913
- bladder exstrophy, 5593, 5594, 5595, 5596, 5597, 5598, 5599
- blast injury, 4011, 4012, 4013, 4014, 4015, 4017, 4018, 4020, 4021, 4023, 4026, 4029, 4034, 4037
- blast, 705, 3116, 3406, 3776, 3968, 3969, 4011, 4012, 4013, 4014, 4015, 4017, 4018, 4019, 4020, 4021, 4023, 4025, 4026, 4029, 4030, 4034, 4036, 4037, 4039, 4040, 4043, 4932, 5654, 5655, 5660

- bleeding rates, 2513, 2521, 2522, 4311
- blood flow velocity, 980, 996, 3461, 3800, 3822, 7215, 7216
- blood type-incompatible, 5464, 5468
- blood viscosity, 413, 3076, 3077, 3079, 3081, 3094, 3096, 3098, 3103, 3107, 3110, 3112, 3806, 4785, 4786, 4850, 4955, 4956
- blood-brain barrier, 906, 967, 981, 997, 1073, 1160, 1659, 3351, 3370, 3666, 3690, 3703, 3766, 3776, 4000, 4556, 4850, 7120
- body image dissatisfaction, 642, 7133, 7140, 7143, 7146
- body mass index, 144, 151, 159, 163, 164, 172, 176, 179, 206, 209, 211, 241, 262, 263, 264, 295, 313, 322, 499, 503, 505, 512, 772, 794, 803, 813, 827, 1460, 1465, 1487, 1601, 1867, 2089, 2150, 2157, 2171, 2172, 2572, 2674, 2677, 2684, 2690, 2692, 2695, 2730, 2735, 2745, 2832, 4239, 4248, 4263, 4348, 4500, 4527, 4533, 4537, 4562, 4596, 4617, 4625, 4643, 4664, 5046, 5086, 5265, 5274, 5333, 5335, 5345, 5348, 5415, 5417, 5465, 5643, 5758, 6031, 6351, 6352, 6354, 6360, 6362, 6431, 6861, 6864, 6952, 6978, 6986, 6987, 6990, 7032, 7129, 7169, 7170, 7174, 7175, 7176, 7182, 7196, 7257
- bomb blast, 4011, 4012, 4013, 4014, 4015, 4016, 4017, 4026
- bone defect, 70, 72, 73, 121, 122, 123, 128, 134, 347, 1737, 1740, 1742, 1743, 1749, 1751, 1752, 2200, 2210, 2293, 2294, 2295, 2296, 2297, 2299, 2300, 2304, 2307, 2315, 2318, 3366, 3368, 3559, 3567, 3568, 3570, 3575, 3576, 3577, 3578, 3579, 3581, 3988, 6097
- bone flap resorption, 3905, 3915, 4000, 4001, 4008, 4078, 4086, 4087, 4090
- bone fractures, 70, 86, 1375, 1768, 3539, 3557, 3559, 3568, 3570, 3574, 6232, 6235, 6236
- bone grafting, 119, 131, 351, 1733, 1737, 1738, 1739, 1740, 1741, 1744, 1751, 1752, 2262, 2298, 2308, 2309, 3559, 3566, 5578
- bone lengthening, 6, 11, 30, 37, 46, 49, 52, 54, 55, 56, 57, 64, 66, 67, 74, 101
- bone marrow stimulation, 3537, 3540, 3542, 3546, 3548, 3549
- bone marrow transplantation, 2915, 2916, 2917, 2918, 2921, 2935, 2936, 2937, 3268, 3292, 3295, 3298, 3299, 3348, 3661, 3662, 3664, 3696
- bone marrow, 6, 10, 74, 75, 322, 350, 351, 1168, 1734, 1845, 1869, 2153, 2195, 2209, 2232, 2233, 2244, 2245, 2915, 2916, 2917, 2918, 2921, 2923, 2924, 2926, 2931, 2933, 2935, 2936, 2937, 2990, 2997, 3085, 3107, 3263, 3268, 3269, 3286, 3287, 3292, 3295, 3298, 3299, 3301, 3348, 3358, 3363, 3372, 3415, 3537, 3538, 3539, 3540, 3541, 3542, 3543, 3544, 3546, 3548, 3549, 3552, 3554, 3555, 3558, 3561, 3566, 3567, 3570, 3574, 3578, 3580, 3599, 3648, 3650, 3652, 3653, 3655, 3657, 3660, 3661, 3662, 3663, 3664, 3696, 3734, 5249, 5253, 5307, 5429, 5650, 5653, 5654, 5655, 5656, 5657, 5658, 5659, 5660, 5661, 5662, 5663, 5667, 5706, 5707, 5796, 6412, 6423, 6424, 6556, 7126
- bone marrow-derived mesenchymal stem cells, 3538, 3542, 3554, 3555, 3558, 3566, 3570, 6412
- bone mineral density, 10, 79, 83, 84, 85, 283, 292, 293, 1776, 3348, 3563, 3566, 3569, 5429, 6225, 6226, 7186, 7193, 7201, 7202
- bone morphogenetic protein, 174, 1731, 1735, 3538, 3543, 3549, 3552, 3553, 3555, 3560, 3561, 3566, 3576
- bone pain, 1195, 1314, 5609, 5610, 5611, 5614, 5773, 6051, 6052, 6054, 6055
- bone remodeling, 125, 3373, 3546, 3559, 3560, 3561, 3564
- bone sarcomas, 2312
- bone tumor, 2311, 2312, 2314, 2315, 2317, 2318, 2319, 2321, 2330, 2331, 3559, 5516, 5533, 5560, 5561, 5563, 5568, 5666, 5667, 5673, 5721, 5722, 5727, 5729, 5731, 5732, 5736, 5738
- botulinum toxin type A, 537, 538, 539, 554, 555, 556, 557, 1753, 1759, 1760, 1762
- botulinum toxin, 353, 362, 537, 538, 539, 540, 541, 542, 543, 544, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 569, 570, 573, 1041, 1044, 1045, 1311, 1753, 1759, 1760, 1761, 1762, 1763, 1800, 1811, 1899, 2098, 2452, 2707, 3122, 3128, 3538, 6590, 6608
- boundary condition, 3461, 3462, 3463, 3476, 5886, 5887, 5888, 5892, 5893, 5894, 5896
- bovine, 561, 562, 563, 565, 566, 571, 574, 1592, 1724, 1737, 1738, 1745, 1749, 1752, 2565, 2567, 2575, 2757, 2770, 2936, 2940, 2953, 2999, 3024, 3025, 3058, 3086, 3358, 3480, 3484, 3507, 3541, 3543, 3552, 3554, 3652, 3662, 3739, 4548, 4549, 4745, 4827, 4946, 4966, 5328, 5918, 5923, 5928, 6505, 6536, 6540, 6541
- bowel obstruction, 145, 146, 259, 779, 1092, 1093, 1107, 1336, 1342, 1845, 1851, 1852, 1853, 1855, 1858, 1952, 1987, 1989, 2009, 2010, 2011, 2019, 2020, 2074, 2743, 2747, 4599, 4603, 4607, 4609, 4628, 4674, 4691, 4823, 5747, 5749, 5986, 6011, 6997, 7006, 7134
- box trainer simulators, 2770, 2779
- box trainer, 702, 2770, 2777, 2779
- bradyarrhythmia, 7279, 7280
- brain death, 3040, 3046, 3060, 3070, 3480, 3488, 3507, 3510, 3812, 3875, 3891, 3908, 3915

- brain ischemia, 3357, 3792, 3827, 3839, 3847, 3889, 3892, 3895, 7058, 7060, 7210
- brain mapping, 1166, 1167, 7097, 7098, 7100, 7101, 7103, 7111, 7112, 7113, 7115
- brain oxygen delivery, 3841, 3842
- Brain Trauma Foundation, 3804, 3824, 3844, 3845, 3854, 3950, 3959, 3970, 3988, 4002, 4006, 4038, 4046, 4047, 4066, 4067, 4104
- brainstem, 889, 992, 1171, 1180, 1613, 1636, 1883, 1884, 3401, 3700, 3766, 3817, 3820, 3879, 3895, 3932, 3940, 4021, 4022, 4024, 4119, 4120, 4121, 4122, 4123, 4124, 4125, 4126, 4127, 4128, 4129, 4130, 4131, 4132, 4133, 4134, 4135, 4138, 4512, 6101, 7322, 7323
- breaks, 431, 1732, 1889, 2078, 2080, 2140, 3306, 4614
- breast reconstruction, 456, 471, 480, 489, 494, 500, 509, 512, 514, 1366, 1405, 1406, 1407, 1408, 1409, 1410, 1411, 1412, 1413, 1414, 1415, 1416, 1417, 1418, 1419, 1421, 1422, 1423, 1424, 1425, 1426, 2551, 2552, 2555, 2559, 2560, 2561, 2562, 2563, 2565, 2566, 2567, 2569, 2571, 2572, 2574, 2575, 2576, 2577, 2578, 2579, 2583, 2584, 2586, 2587, 2590, 2591, 2592, 2593, 2594, 2595, 2596, 2597, 2598, 2599, 2600, 2601, 2602, 2603, 2604, 2605, 2607, 2608, 2612, 2613, 2614, 2615, 2616, 2626, 2628, 2629, 2630, 2631, 2635, 2636, 2637, 2639, 2640, 2641, 2642, 2643, 2644, 2645, 2646, 2647, 2648, 2649, 2661, 2663, 2666, 2668, 2669, 2670, 2673, 2674, 2675, 2676, 4698, 6376, 6379, 6420, 6774
- BREAST-Q, 603, 608, 2585, 2592, 2593, 2596, 2600, 6373, 6376, 6377, 6378, 6379, 6380
- bronchoscopy, 1319, 2389, 2390, 2391, 2392, 2395, 2397, 2398, 2399, 2401, 2402, 2500, 3890, 4147, 4160, 4453, 6062, 6063, 6081
- buccal mucosa graft, 4342, 6153, 6158
- bumper, 1867, 1912, 1913, 1914, 1915, 1917, 1928, 1929, 1942, 1943, 1944, 1950, 1952, 1963, 1965, 1969, 1998, 1999, 2002, 2014, 2018, 2019, 2027, 2028, 2029, 2030, 2031, 2032, 2035, 2044, 2047, 2051, 2052, 2060, 2064, 2066, 2071, 2079, 2081, 2083, 2084, 2089, 2091, 2092, 2093, 2094
- Bundesarbeitsgemeinschaft Rehabilitation, 1036
- buprenorphine, 2841, 2850, 2853, 2859, 2862, 2973, 3274, 3275, 3280, 3281, 3283, 3284, 3290, 3294, 3295, 3297, 3298, 3299, 3300, 3309, 3311, 3384, 3385, 3388, 3396, 3420, 3421, 3630
- Burch Colposuspension, 4367, 4382, 4383, 4384, 4393, 4394
- Burch urethropexy, 4382
- buried bumper syndrome, 1969, 2029, 2031, 2035, 2047, 2083, 2084, 2085, 2089
- buried bumper, 1915, 1969, 2029, 2031, 2035, 2047, 2083, 2084, 2085, 2089
- buttressing, 141, 149, 1721, 2445, 2754, 2757, 4297, 4545, 4548, 4549, 6998, 7003
- bypasses to crural vessels, 4895

- carotid artery disease, 1082, 1083, 4725, 4728, 4867, 7227
- carotid artery injury, 2500, 4017, 6106, 6107
- carotid artery surgery, 4849
- carotid artery, 878, 879, 880, 886, 887, 888, 889, 891, 892, 895, 914, 928, 946, 1010, 1011, 1071, 1082, 1083, 1084, 1085, 1088, 1089, 1195, 1477, 1479, 1480, 1481, 1521, 1610, 1611, 1660, 1687, 1978, 2500, 2818, 3140, 3179, 3342, 3379, 3380, 3477, 3584, 3586, 3621, 3692, 3725, 3812, 4017, 4723, 4725, 4726, 4728, 4738, 4754, 4757, 4783, 4812, 4849, 4850, 4853, 4858, 4860, 4863, 4864, 4865, 4866, 4867, 4868, 4869, 4881, 4946, 4984, 4999, 5000, 5011, 5518, 5519, 6089, 6096, 6099, 6103, 6106, 6107, 6108, 6500, 7211, 7212, 7214, 7215, 7216, 7219, 7220, 7221, 7227
- carotid cavernous fistula, 4017, 6089, 6091, 6099, 6104
- carotid endarterectomy, 1089, 3831, 4742, 4831, 4849, 4850, 4856, 4857, 4858, 4860, 4862, 4863, 4865, 4866, 4868, 4982, 4999, 5011, 7209, 7210, 7211, 7218, 7219, 7220, 7221, 7226, 7228
- carotid occlusive disease, 4849
- cartilage degeneration, 3547
- cartilage regeneration, 3540, 3544, 3551, 3552
- cartilage trauma, 3540
- cataract surgery, 1710, 1715, 1717, 1718, 1719, 1720, 1880, 5850, 5851, 5853, 5855, 6696, 6697, 6881, 6883, 6885, 6890, 6891, 6893, 6899, 7091
- cataract, 1710, 1714, 1715, 1717, 1718, 1719, 1720, 1880, 3172, 3173, 3186, 5850, 5851, 5852, 5853, 5854, 5855, 6687, 6689, 6696, 6697, 6698, 6881, 6883, 6885, 6890, 6891, 6893, 6895, 6898, 6899, 7091, 7092, 7155
- catheter associated urinary tract infections, 3901
- causes of weight regain, 827, 871, 2689, 7002
- cauterization, 496, 1610, 2031, 2415, 2421, 2464, 2485, 2521, 3165, 4424, 6033, 7311, 7315, 7316, 7317
- CEAP classification, 4951, 4952, 4965
- cell therapy, 2561, 3246, 3443, 3480, 3499, 3547, 3548, 3555, 3557, 3562, 3566, 3569, 3570, 3578, 3580, 3653, 4888, 6262, 6413, 6926
- cellular properties, 3080
- cellulitis, 143, 524, 1528, 2086, 2098, 2665, 3142, 4674, 4730, 4953, 4955, 4967, 6999
- central cannulation, 6463, 6465, 6514, 6519
- central line associated bloodstream infections, 3901
- cerebral aneurysm, 877, 882, 907, 913, 915, 916, 917, 918, 919, 935, 939, 940, 945, 955, 956, 960, 962, 963, 964, 965, 967, 1015, 1017, 1032, 1077, 1663, 2380, 3254, 3474
- cerebral arteries, 885, 886, 890, 893, 897, 901, 903, 904, 914, 935, 951, 980, 1004, 1005, 1073, 1612, 3767, 4037, 4775, 6102
- cerebral blood flow, 905, 911, 964, 971, 972, 975, 976, 994, 997, 1015, 1069, 1070, 1071, 1072, 1073, 1074, 1075, 1161, 1165, 1166, 1175, 1610, 1632, 3092, 3338, 3356, 3370, 3666, 3689, 3702, 3707, 3711, 3773, 3781, 3783, 3787, 3789, 3792, 3794, 3796, 3806, 3811, 3825, 3827, 3828, 3830, 3831, 3839, 3842, 3844, 3847, 3848, 3849, 3855, 3866, 3868, 3870, 3888, 3889, 3890, 3891, 3899, 3921, 3925, 3929, 3953, 3958, 3988, 3992, 4005, 4046, 4048, 4053, 4077, 4086, 4096, 4105, 4857, 6099, 7210, 7212, 7214, 7215, 7216, 7217
- cerebral edema, 1169, 1170, 3317, 3319, 3769, 3770, 3774, 3775, 3776, 3777, 3788, 3789, 3809, 3813, 3819, 3820, 3841, 3848, 3854, 3855, 3861, 3864, 3865, 3866, 3867, 3868, 3879, 3885, 3891, 3900, 3917, 3919, 3927, 3932, 3934, 3938, 3947, 3956, 3959, 3963, 3964, 3968, 3987, 3992, 3996, 3997, 4006, 4007, 4014, 4030, 4035, 4037, 4045, 4046, 4050, 4071, 4077, 4078, 4090, 4101, 4114, 4423, 5000, 5778
- cerebral hypoperfusion, 967, 993, 3805, 3823, 3919, 3932, 4999, 7059, 7210, 7212, 7215
- cerebral ischemia, 911, 962, 977, 982, 990, 991, 995, 998, 999, 1015, 1033, 1173, 1181, 1611, 1613, 1614, 3101, 3689, 3690, 3691, 3692, 3701, 3711, 3712, 3713, 3778, 3781, 3787, 3788, 3790, 3792, 3796, 3797, 3814, 3829, 3830, 3838, 3842, 3847, 3860, 3908, 3947, 3963, 3993, 4105, 4723, 4762, 4875, 7209, 7210, 7211, 7216, 7217, 7218, 7220, 7221

- cerebral metabolic rate for glucose, 3783
- cerebral metabolic rate of oxygen, 972, 3789, 3807, 3811, 4048
- cerebral microdialysis, 3809, 3814, 3815, 3817, 3820, 3829, 3835, 3845, 3846, 3847, 3848, 3864, 3889
- cerebral oedema, 906, 967, 968, 3990
- cerebral palsy, 1753, 1754, 1760, 1761, 1762, 1763, 1765, 1766, 1767, 1768, 1769, 1771, 1772, 1773, 1775, 1776, 1777, 1779, 1780, 1781, 1787, 1789, 1790, 1791, 1792, 1793, 1794, 1799, 1800, 1801, 1802, 1810, 1811, 1812, 1813, 1815, 1816, 1819, 1824, 1827, 1828, 1829, 1830, 2546, 3666, 3688, 3689, 3690, 3701, 3705, 5854, 5867, 5868, 5872, 5874, 5878, 5879, 5880, 6955, 6956, 6958, 6959, 6963
- cerebral perfusion pressure, , 968, 972, 980, 994, 1009, 1074, 1075, 3784, 3794, 3799, 3800, 3810, 3822, 3823, 3825, 3826, 3827, 3828, 3830, 3837, 3848, 3850, 3851, 3852, 3867, 3869, 3887, 3889, 3891, 3894, 3909, 3912, 3913, 3929, 3958, 3962, 3964, 3975, 3981, 3987, 3990, 3993, 4006, 4019, 4052, 4068, 4104, 4134
- cerebral perfusion, , 881, 946, 968, 972, 980, 985, 989, 991, 992, 993, 994, 1009, 1015, 1071, 1074, 1075, 1451, 1643, 3364, 3784, 3794, 3799, 3800, 3805, 3810, 3815, 3822, 3823, 3825, 3826, 3827, 3828, 3829, 3830, 3837, 3848, 3850, 3851, 3852, 3867, 3869, 3887, 3889, 3891, 3894, 3909, 3912, 3913, 3927, 3929, 3958, 3962, 3964, 3970, 3975, 3981, 3987, 3990, 3993, 4006, 4019, 4046, 4052, 4058, 4059, 4068, 4096, 4104, 4109, 4110, 4134, 4760, 4761, 4763, 4764, 4765, 4777, 4778, 6558, 6564, 6565, 7061, 7075, 7215, 7216, 7217, 7218
- cerebral pressure reactivity index, 3855
- cerebral protection strategies, 4753
- cerebral protection, 4071, 4753, 4761, 4762, 4763, 4764, 4862, 7221, 7228
- cerebral vasospasm, 881, 884, 925, 939, 962, 967, 968, 971, 976, 979, 982, 985, 987, 988, 990, 998, 1001, 1015, 1016, 1019, 1020, 1023, 1066, 1073, 1074, 1075, 1076, 1077, 3825, 3900, 4037, 4038, 4040, 6100, 6104, 6108
- cerebral veins, 885, 898, 899, 900, 901, 902, 1662
- cerebral venous thrombosis, 1184, 3372, 3864, 3872
- cerebrospinal fluid (CSF) leak, 1614, 1695, 1705, 1706, 2435, 3903, 4017, 4031, 4042, 6089, 6091, 6163, 6955, 7331
- cerebrospinal fluid, 905, 934, 938, 940, 943, 981, 987, 1019, 1020, 1023, 1024, 1039, 1043, 1070, 1073, 1074, 1614, 1654, 1695, 1705, 1706, 2111, 2435, 3314, 3774, 3778, 3786, 3792, 3796, 3800, 3801, 3802, 3814, 3822, 3829, 3836, 3869, 3883, 3889, 3903, 3911, 3940, 3950, 3951, 3970, 4017, 4031, 4041, 4042, 4058, 4072, 4081, 4090, 4096, 4796, 4809, 5790, 6089, 6091, 6117, 6163, 6206, 6955, 7331
- cerebrovascular pressure reactivity, 3808, 4082
- cervical cancer, 3136, 3154, 4399, 4400, 4402, 4405, 4412, 4413, 4414, 4418, 4425, 4432, 4433, 4435, 4436, 4438, 4439, 4440, 4441, 4444, 4445
- charing cross venous ulcer questionnaire, 4954
- Chilaiditi syndrome, 1987
- childhood sexual abuse, 7133, 7141, 7146, 7147
- chimerism, 2925, 2926, 2927, 2929, 2931, 2932, 2933, 2934, 2936, 3291, 3293, 3425, 3605, 3628, 3639, 3642, 3643, 3644, 3647, 3650, 3652, 3653, 3654, 3655, 3656, 3659, 3660, 3661, 3662, 5758
- China, 288, 645, 662, 749, 767, 1615, 1617, 1709, 1749, 2360, 2729, 3023, 3030, 3031, 3038, 3039, 3159, 3163, 3164, 3200, 3202, 3647, 3658, 3731, 3732, 3738, 3818, 3938, 3941, 4048, 4049, 4062, 4063, 4750, 5491, 5629, 5803, 5832, 6411, 6581, 6597, 7223
- chitosan, 92, 3543, 3545, 3546, 3548, 3549, 3552, 3553, 3566, 3572, 3728
- CHIVA- conservative ambulatory hemodynamic management of varicose veins, 4965
- chlorhexidine, 1430, 1862, 1908, 3385, 3416, 3417, 3884, 4369, 4390, 4633, 4634, 4636, 4648, 4649, 4650, 4652, 4676, 4678, 4679, 4686, 4691, 4692, 4712, 4718, 4719, 4720, 6255
- choanal atresia, 1691, 1692, 1704, 1705
- cholangiocarcinoma, 1589, 1893, 2865, 2866, 2901, 2904, 2905, 2908, 2912, 2913, 5259, 5799, 5800, 5801, 5802, 5803, 5804, 5805, 5806, 5807, 5808, 5809, 5811, 5812, 5813, 5814, 5815, 5816, 5817, 5819, 5823, 5830, 5831, 5832, 5833, 5834, 5835, 5836, 5838, 5839, 5842, 5843, 5844, 5845, 5846, 5848, 6907, 6908, 6910, 6911
- cholelithiasis, 145, 260, 1240, 2741, 2763, 2770, 2897, 2905, 2909, 4537, 4538, 4539, 4540, 4541, 4542, 4543, 7001
- chondrocyte morphology, 3546
- chondrocyte phenotype, 3541, 3543, 3544
- chondrocytes, 3537, 3538, 3539, 3540, 3541, 3543, 3544, 3545, 3546, 3547, 3548, 3549, 3550, 3551, 3552, 3553, 3554, 3555, 3561, 6412
- chondrogenesis, 73, 3540, 3541, 3542, 3543, 3547, 3548, 3549, 3550, 3551, 3552, 3553, 3554, 3555, 3561, 3568
- chondrogenic, 3537, 3539, 3541, 3542, 3543, 3544, 3545, 3546, 3548, 3550, 3551, 3553, 3554, 3555, 3570, 5672, 6415, 6570

- chondrosarcoma, 2312, 2314, 2331, 5665, 5666, 5667, 5669, 5670, 5671, 5672, 5673, 5674, 5711, 5712
 chordoma, 1636, 5563, 5564, 5565, 5566, 5567, 5568, 5569, 6090
 chronic complications, 1434, 2077, 2088, 5445, 6002, 6359
 chronic hydrocephalus, 938, 1019, 1021, 1023, 1024, 1025
 chronic mesenteric ischemia, 4727, 4840, 4848
 chronic myeloid leukemia, 5653, 5654, 5662, 5663
 chronic pain, 267, 269, 286, 297, 320, 347, 836, 1493, 3281, 3297, 4141, 4479, 4491, 5012, 5571, 5612, 5613, 5868, 5878, 6161, 6164, 6169, 6170, 6171, 6185, 6186, 6200, 6203, 6214, 7038, 7041, 7043, 7044, 7045, 7046, 7047, 7048, 7230, 7231, 7235
 chronic rhinosinusitis, 1683, 1685, 1686, 1687, 1688, 1701, 1702, 2403, 2406, 2412, 2429, 2430, 2433, 2438, 2439, 2457
 chronic venous insufficiency, 4730, 4749, 4877, 4920, 4933, 4934, 4949, 4950, 4951, 4957, 4967
 circular anastomosis, 4917, 5101, 5129, 5130, 5137
 circulatory arrest, 3490, 3519, 3667, 3692, 3705, 4762, 4777, 4778, 4809, 4978, 4991, 5912, 5924, 5935, 5936, 6470
 claudication, 4724, 4811, 4813, 4815, 4816, 4818, 4821, 4838, 4845, 4846, 4871, 4872, 4873, 4874, 4880, 4881, 4882, 4885, 4886, 4887, 4889, 4897, 4899, 4900, 4901, 4906, 4908, 4945, 4987
 clear cell chondrosarcoma, 5665, 5666, 5668, 5669, 5670, 5671, 5672, 5673

- conus medullaris syndrome, 5585, 5586, 5589, 5590, 5591, 5592
- conventional carotid endarterectomy, 4858, 4868
- conventional ultrasound, 5334, 6635
- conventional ventilation, 7160, 7161
- conversion from XFS to XFG, 6884
- conversion to laparotomy, 4399, 4404, 4410, 4418, 6291, 6396, 6397, 6398, 6399, 6400, 6401, 6402, 6403, 6404, 6405, 6406, 7231, 7243
- core body temperature, 3405, 3878
- Cor-Knot, 4193, 4195, 6463, 6502, 6733, 6735, 6738, 6739
- corneal cautery, 7316
- corneal transplantation, 1709, 1714, 1718
- coronary artery bypass surgery, 3154, 3715, 4216
- coronary artery bypass surgery, 5881, 5882, 5920, 5931, 5932, 5933, 5934, 6555, 6597, 6601, 6606, 6610, 6843, 6860, 6868, 7073, 7077, 7079, 7165
- coronary artery ligation, 2840, 2841, 3355, 3672, 3708
- coronary heart disease, 179, 238, 249, 763, 1038, 1872, 4800, 4845, 4888, 5286, 5383, 5413, 5881, 5888, 5893, 5894, 5895, 7130
- coronary ligation, 3347, 3705
- cortical mapping, 7099
- corticosteroids, 295, 313, 444, 984, 1329, 1522, 1852, 1858, 2394, 2497, 2927, 2930, 3307, 3319, 3539, 3566, 3568, 3650, 3757, 3777, 4103, 4453, 4515, 4517, 5708, 5951, 5958, 5983, 6004, 6010, 6194, 7286
- coupled momentum method, 3461, 3475
- covered PEG, 2045
- CPB and AoX, 6540, 6542, 6543, 6736, 6764
- cranial nerve palsies, 992, 4017
- cranial vault reconstruction, 6665, 6666, 6679, 6681
- craniofacial injuries, 4014, 4024
- cranioplasty, 1043, 1621, 3766, 3848, 3872, 3905, 3915, 3952, 3953, 3954, 3984, 3991, 3995, 4000, 4001, 4008, 4026, 4034, 4036, 4039, 4041, 4043, 4060, 4061, 4068, 4071, 4072, 4073, 4074, 4075, 4076, 4077, 4078, 4079, 4081, 4083, 4085, 4086, 4087, 4090, 6429, 6667, 6675, 6676, 6678, 6683, 6684
- craniosynostosis, 6665, 6666, 6667, 6669, 6671, 6672, 6673, 6674, 6675, 6676, 6679, 6680, 6681, 6682, 6683, 6684, 6685
- CRASH model, 4094, 4095, 4111
- critical illness, 1037, 1040, 1045, 1054, 1507, 2442, 2826, 3335, 3943, 4569, 4629
- critical limb ischemia, 3346, 4724, 4727, 4811, 4812, 4813, 4814, 4815, 4816, 4873, 4874, 4877, 4881, 4886, 4908, 4909, 4915, 6172, 6428
- critical size defects, 3562
- cross-clamp times (AoX), 6538
- cross-facial nerve graft, 1665, 1666, 1667, 1668, 1669, 1670, 1671, 1672, 1673, 1674, 1675, 1676, 1677
- cryoablation, 1886, 3154, 3395, 3409, 4199, 6055, 6775, 6784, 6832, 6833, 6834, 6836
- cryoischemia, 3774
- cryopreserved, 3028, 3747, 3759, 4001, 4023, 4060, 4946, 4988, 4989, 5010
- cryotherapy, 420, 623, 624, 629, 1349, 1527, 2087, 6051
- CSF leak, 1679, 1688, 1695, 3884, 3984, 4018, 4022, 4023, 4024, 4025, 4036, 6118, 6119, 6120, 6122, 6179, 6956, 6957, 6958, 6959, 7326
- CT classifications, 4120
- CT-angiography, 1612, 4721, 4722, 4734, 4737, 4738, 4739, 4746, 4817, 4883
- Cushing, 877, 878, 879, 997, 1071, 1208, 1213, 1220, 1610, 3959, 3963, 3970, 3972, 3988, 4013,

- 4030, 4795, 6090, 6101, 6105, 6110, 6118, 6121, 6129, 6546, 7101
- custom implants, 587, 2275, 2276, 2293, 2323, 5876
- customized cranial implant, 4073, 4074, 4077
- cut and push', 2089, 2094
- Cutan section, 2834, 2835
- cut-and-push' method, 2081
- CV5 GORE-TEX, 6733
- cyanoacrylate, 386, 390, 882, 1436, 1736, 1892, 4667, 4668, 4669, 4670, 4711, 4714, 4962, 5923, 6641
- CyberKnife® system, 705
- cyclooxygenase-2, 3538, 3558, 3560, 3566, 4491, 4515, 4559, 4567, 4568

E

- early and delayed injury, 905
- early extubation, 6726, 7157, 7162, 7167, 7274, 7277, 7278
- early postoperative period, 143, 147, 444, 1571, 1724, 1757, 1773, 1999, 2742, 3307, 3329, 4522, 4540, 4607, 4826, 4978, 4979, 4980, 4982, 4985, 5000, 5840, 6294, 6319, 6866, 6867, 6902, 6903, 6904, 6905, 7000, 7073
- early vascular complications, 4981
- eating behaviors, 7130, 7137, 7138, 7139, 7145
- eating disorders, 843, 870, 1766, 2121, 2694, 5230, 6358, 6369, 7002, 7129, 7132, 7137, 7138, 7140, 7142, 7143, 7145, 7149
- echocardiogram, 1725, 1873, 4189, 4190, 4194, 5102, 6486, 6789, 6798, 6819, 6853, 7298
- echocardiography, 1873, 1881, 2489, 2824, 2853, 3338, 3340, 3403, 3584, 3587, 3606, 3607, 3638, 4198, 4202, 4203, 4206, 4207, 4761, 4766, 4776, 4784, 4785, 4801, 4804, 4886, 5881, 5883, 5884, 5885, 5886, 5894, 5901, 5903, 5908, 6461, 6469, 6470, 6471, 6474, 6477, 6479, 6480, 6484, 6495, 6501, 6513, 6522, 6555, 6617, 6713, 6717, 6725, 6726, 6733, 6734, 6744, 6745, 6757, 6758, 6770, 6775, 6789, 6790, 6817, 6821, 6827, 6833, 6860, 6861, 6868, 7076
- ectopic models, 3562
- ectropion, 378, 380, 383, 384, 6439, 6449, 6451
- effectiveness of the treatment, 1497, 1498, 1501
- efficiency, 90, 103, 662, 684, 685, 689, 843, 844, 854, 1096, 1323, 1436, 1444, 1446, 1470, 1581, 1584, 1766, 1769, 1772, 1773, 1774, 1811, 2143, 2419, 2588, 2768, 2769, 2793, 2992, 3002, 3125, 3130, 3152, 3210, 3246, 3342, 3355, 3374, 3522,

- 3751, 4261, 4265, 4266, 4363, 4369, 4404, 4405, 4406, 4424, 4431, 4466, 4978, 4979, 5467, 5890, 5892, 5901, 6118, 6122, 6123, 6307, 6333, 6361, 6408, 6475, 6590, 6636, 6714, 6783, 6916, 7151, 7154, 7155, 7216, 7225, 7316
- Egypt, 2692, 2694, 3159, 3162, 3163, 4780
- elastance function, 3452, 3453, 3454
- elasticity, 6, 10, 71, 79, 344, 345, 364, 402, 565, 576, 883, 907, 983, 1378, 2253, 2956, 2988, 3001, 3078, 3084, 3356, 3363, 3451, 3541, 3547, 3548, 4996, 5311, 5337, 5338, 5511, 6231, 6330, 6416
- electrical injury, 5432, 5434, 5435, 5438, 5440
- electrocardiogram, 1872, 1876, 1880, 3277, 3338, 3343, 3375, 3376, 3402, 3405, 3420, 3422, 3637, 4872, 4879, 6832, 6833
- electrocautery, 364, 444, 1409, 1527, 1866, 1867, 2091, 2343, 2493, 2494, 2497, 2499, 2501, 2502, 2506, 2507, 2508, 2510, 2515, 2516, 2519, 2520, 2521, 2523, 2525, 2527, 2534, 2784, 3017, 4077, 4194, 4203, 4204, 4205, 4223, 4230, 4252, 4430, 5926, 6092, 6462, 6562, 6594, 6609, 6667, 6791, 6941, 6957, 6959
- electrocoagulation, 1886, 6029, 6031, 6033, 6038, 6042
- electroencephalography, 995, 3402, 3815, 3832, 3889, 5777, 5780, 5784, 7075, 7076, 7215, 7216
- electrolytes disorders, 3314
- electrolytes, 971, 973, 1602, 2820, 3276, 3278, 3308, 3313, 3314, 3316, 3317, 3329, 3330, 3331, 3333, 3481, 3484, 3895, 4024, 4879, 4882, 4886, 4939, 5656, 5956, 6013, 7277, 7286
- electromagnetic tracking systems, 683
- electron microscopy, 488, 2988, 3059, 3573, 3695, 3786, 3837, 3840, 5291, 5307, 5311, 5702, 5707, 6593
- electron transport chain, 3782, 3783, 3786, 3787, 3788, 3789, 3790
- electrophysiological monitoring, 999
- electrophysiology, 717, 957, 961, 3478, 3815, 3839
- electrosurgery, 1867, 2498, 2504, 2505, 2511, 2516, 4242, 4247, 4255
- elephant trunk procedure, 4765, 4769, 4770, 4777, 4806
- elephant trunk, 4765, 4769, 4770, 4771, 4774, 4777, 4778, 4779, 4791, 4806, 6470
- embolectomy, 4741
- embolism, 137, 141, 142, 143, 145, 157, 215, 268, 290, 296, 318, 321, 343, 346, 414, 420, 531, 1012, 1038, 1203, 1444, 1451, 1587, 1588, 1644, 1661, 3065, 3191, 3306, 3932, 4039, 4195, 4390, 4529, 4725, 4762, 4763, 4777, 4840, 4852, 4863, 4864, 4877, 4879, 4893, 4898, 4901, 4905, 4919, 4927, 4979, 4984, 5919, 6089, 6226, 6243, 6248, 6259, 6491, 6492, 6539, 6556, 6683, 6769, 6826, 6833, 6999, 7060, 7075, 7076, 7077, 7079, 7212, 7214, 7324
- emesis, 1449, 1450, 1452, 2011, 2497, 2719, 3396, 3400, 3404, 4512, 4515, 4516, 4524, 5746, 7087, 7089, 7090, 7092, 7094
- encapsulation, 2984, 3721, 3722, 3723, 3724, 3728, 3730, 3731, 3736, 3737, 3739, 3740, 3741, 3743, 3744
- encephaloceles, 1692, 1693, 1694, 1695, 1705, 1706, 4036
- end tidal CO₂, 1876, 1883, 3807, 3859, 3884
- endarterectomy, 1089, 4721, 4723, 4742, 4743, 4821, 4824, 4841, 4843, 4849, 4850, 4851, 4856, 4857, 4858, 4859, 4860, 4861, 4862, 4863, 4864, 4865, 4866, 4867, 4868, 4869, 4875, 4879, 4885, 4887, 4894, 4897, 4909, 4999, 5011, 7219, 7220, 7221
- endoballoon, 4190, 6734, 6736, 6737, 6852
- endobronchial ultrasound, 1721, 2389, 2390, 2398, 2399, 2400, 2402
- endobronchial valves, 2389, 2390, 2393, 2397, 2400, 2401
- endochondral ossification, 3545, 3561, 3567, 3571, 3574
- endoclip technique, 1966
- end-of-life, 1848, 4136, 6382, 6385, 6387, 6388, 6881, 6893
- endoleak, 1081, 1082, 1086, 1087, 1090, 4773, 4774, 4784, 4837, 4838, 4893
- endoluminal, 858, 1995, 2004, 2687, 2791, 2792, 2793, 3131, 3360, 4585, 4941, 4945, 5100, 5943, 6012, 6983, 6990
- endometrial cancer, 698, 714, 3136, 4399, 4400, 4401, 4402, 4403, 4404, 4405, 4407, 4408, 4409, 4410, 4411, 4412, 4418, 4419, 4420, 4422, 4432, 4433, 4434, 4435, 4436, 4437, 4438, 4441, 4442, 4443, 4445, 6277, 6407, 6408
- endometrioma, 4490, 4493, 6031, 6032, 6033, 6034, 6035, 6037, 6038, 6039, 6040, 6041
- endometriosis, 1096, 3149, 3153, 4471, 4477, 4483, 4489, 4490, 4491, 4492, 4493, 4494, 4497, 6029, 6030, 6031, 6032, 6035, 6037, 6038, 6040, 6041, 6042, 7119, 7125
- endometrium, 1601, 2968, 3321, 4407, 4486, 4487, 4489, 4490, 5757, 6304, 7121, 7124
- EndoSAMURAI®, 703
- endoscope, 366, 374, 484, 694, 700, 701, 703, 704, 706, 716, 728, 742, 788, 789, 792, 957, 958, 963, 1326, 1335, 1337, 1483, 1648, 1681, 1682, 1832, 1833, 1903, 1908, 1911, 1913, 1914, 1916, 1917, 1923, 1924, 1927, 1936, 1938, 1940, 1941, 1942, 1944, 1948, 1950, 1951, 1962, 1963, 1964, 1965,

- 1966, 1967, 1968, 1986, 1992, 1996, 1997, 1998, 2002, 2003, 2014, 2017, 2020, 2021, 2044, 2045, 2046, 2069, 2099, 2404, 2785, 2786, 3131, 3132, 3389, 4147, 4204, 4206, 4207, 4210, 4242, 4452, 4476, 5303, 5405, 6061, 6089, 6090, 6101, 6102, 6109, 6118, 6121, 6122, 6210, 6211, 6667, 6670, 6681, 6682, 6683, 6745, 6749, 6763, 6906, 7329
- endoscopic mucosal resection, 703, 1886
- endoscopic procedure, 354, 691, 759, 850, 1235, 1535, 1854, 1862, 1863, 1866, 1867, 1869, 1879, 1908, 1922, 1960, 1967, 1983, 2033, 2055, 2058, 2067, 2074, 2750, 3243, 4177, 5403, 5458
- endoscopic retrograde cholangiopancreatography, 146, 1863, 1996, 2075, 4540, 6907, 7001
- endoscopic sinus surgery, 1679, 1682, 1702, 2403, 2404, 2406, 2407, 2408, 2409, 2417, 2418, 2419, 2423, 2427, 2434, 2437, 2439, 2455, 2459, 2460
- endoscopic surgery, 680, 700, 710, 711, 712, 715, 716, 1536, 1679, 2009, 2022, 2099, 2404, 2405, 2409, 2410, 2420, 2423, 2777, 2785, 2787, 2790, 3151, 3156, 4199, 4448, 6105, 6682
- endoscopic ultrasound (EUS) without fine needle aspiration (FNA), 1863
- endoscopic ultrasound, 1288, 1289, 1291, 1293, 1294, 1333, 1334, 1336, 1338, 1863, 1898, 1998, 2017, 2021, 2402, 4160, 4262, 4276, 5835
- endoscopic-assisted minimally invasive craniectomy (EAC), 6667
- endoscopic-laparoscopic interdisciplinary training entity (ELITE), 2780
- endoscopic-surgery, 6757
- endotension, 4837
- endothelial progenitor cells, 2984, 2997, 3338, 3358, 3362, 3566, 3571
- endothelium-derived P-selectin, 3076
- EndoTower, 2779
- endotracheal suctioning, 3890, 3912
- endovascular aneurysm repair, 1080, 1084, 1086, 1088, 1090, 4805, 4812, 4836, 4838, 4845, 4931
- endovascular intervention, 1002, 1014, 1080, 4038, 4742, 4759, 4774, 4784, 4786, 4791, 4795, 4800, 4802, 4844, 4856, 4885, 4892, 4893, 4938, 4992, 5008, 5899
- endovascular method, 4791, 4795
- endovascular techniques, 1611, 4057, 4058, 4775, 4850, 4856, 4871, 4875, 4897, 4900, 5011, 7299
- endovascular treatment, 884, 919, 945, 946, 952, 954, 955, 1001, 1012, 1014, 1015, 1016, 1017, 1027, 1028, 1031, 3864, 3944, 3945, 4066, 4721, 4723, 4738, 4739, 4746, 4800, 4806, 4810, 4811, 4813, 4819, 4821, 4831, 4834, 4837, 4843, 4844, 4863, 4864, 4869, 4871, 4875, 4878, 4879, 4890, 4892, 4893, 4897, 4900, 4904, 4930, 4932, 4940, 4942, 6090, 6091, 6104, 6106, 6107, 6744
- endovenous ablation procedures, 4958
- endovenous heat-induced thrombosis, 4961
- endovenous laser therapy, 611, 615, 616, 625, 4934, 4960
- endovenous laser treatment, 4957, 4959
- endovenous steam ablation, 4958, 4960
- end-to-end, 1412, 1620, 1670, 1673, 2730, 3188, 3587, 3591, 3592, 3594, 3595, 3624, 4330, 4789, 4822, 4823, 4858, 4966, 4998, 5002, 5748, 5827, 5839, 5942, 5954, 5973, 5974, 5976, 5986, 5996, 5997, 6016, 7335
- energy metabolism, 249, 964, 991, 1510, 2110, 2178, 2181, 2182, 3321, 3438, 3524, 3707, 3711, 3781, 3782, 3783, 3785, 3786, 3787, 3788, 3789, 3790, 3791, 3792, 3797, 3835, 3841, 3842, 3847, 6980, 7194
- enhanced recovery after surgery, 1773, 1778, 2708, 2710, 2714, 2723, 2724, 2727, 4555, 4556, 5016, 5064, 5086, 5102, 5165, 5230, 5840, 7238
- enteral feeding, 1039, 1774, 1831, 1837, 1844, 1849, 1850, 1869, 1893, 1900, 1905, 1917, 1921, 1923, 1930, 1948, 1950, 1957, 1960, 1970, 1995, 2000, 2011, 2019, 2023, 2024, 2034, 2035, 2036, 2060, 2074, 2077, 2088, 2092, 2093, 2095, 2098, 3900, 3901, 4024, 4567, 4627, 4632
- enteral nutrition, 997, 1773, 1774, 1835, 1837, 1838, 1840, 1848, 1849, 1857, 1869, 1888, 1931, 1951, 1955, 1957, 1970, 1994, 2000, 2009, 2010, 2023, 2025, 2034, 2036, 2039, 2067, 2078, 2080, 2089, 2449, 3314, 3330, 3899, 4565, 4572, 4581, 4627, 4629, 4630, 4631, 5950, 6008, 6013, 6017, 6024, 6026
- enterocutaneous fistula, 1952, 2064, 3925, 5955, 5956, 5958, 5963, 6001, 6002, 6003, 6006, 6009, 6011, 6012, 6021
- enterocutaneous fistulae, 5955, 5956, 6009, 6021
- enteroenteric, 1103, 5956, 5958, 5984, 6020, 6027
- enterography, 1104, 1105, 1107, 1108, 5956, 5961, 6008
- enteropathy-associated T-cell lymphoma, 5618, 5630
- eosinophilic esophagitis, 1890, 1902
- epidemiology, 249, 285, 286, 287, 288, 326, 477, 492, 913, 1108, 1570, 1626, 1789, 1858, 1900, 1901, 2596, 2598, 2744, 3713, 3987, 4005, 4045, 4056, 4057, 4064, 4066, 4167, 4257, 4388, 4458, 4541, 4543, 4570, 4611, 4615, 4619, 4620, 4621, 4641, 4651, 4671, 4673, 4683, 4684, 4720, 4747, 4806, 4827, 4834, 4874, 4881, 4890, 4905, 4929, 5265, 5361, 5410, 5427, 5448, 5454, 5455, 5479, 5592, 5627, 5630, 5662, 5945, 5993, 6058, 6079,

- facial fractures, 1528, 4024
- facial nerve, 355, 356, 357, 360, 362, 371, 398, 399, 400, 401, 404, 417, 1528, 1665, 1666, 1667, 1668, 1669, 1670, 1671, 1672, 1673, 1674, 1675, 1676, 1677, 2561, 3191, 5518, 6437, 6438, 6445, 6446, 6447, 6450, 7319, 7323, 7324, 7328, 7333, 7334, 7335, 7341, 7342
- facial pain, 1685, 1688, 1697, 1700, 2379, 2431, 2436, 7323
- facial reanimation, 1666, 1670, 1672, 1673, 1674, 1675, 1676, 1677, 6450, 7341, 7342, 7343
- facial transplantation, 3647, 3653, 3656, 3657
- fail back surgery syndrome, 6203
- failed back surgery syndrome, 6161, 6162, 6168, 6169, 6170, 6171, 6172, 6187, 6212, 6213, 6214
- failing heart, 2862, 6618

- false aneurysm, 4827, 4828, 4882, 4884, 4932, 4942, 4975, 4995, 4996, 6567
- familial adenomatous polyposis, 1895, 3442
- Fas Binding Factor 1, 4792
- fasting, 169, 181, 186, 189, 191, 192, 193, 195, 196, 197, 198, 199, 200, 201, 203, 222, 226, 228, 257, 260, 764, 765, 766, 767, 769, 784, 785, 787, 1472, 1491, 1506, 1602, 1773, 1908, 1917, 2004, 2105, 2119, 2128, 2134, 2141, 2142, 2143, 2144, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2159, 2160, 2162, 2167, 2174, 2177, 2178, 2185, 2453, 2681, 2705, 2717, 2725, 2732, 2734, 2741, 2808, 3276, 3303, 3307, 3329, 3389, 4057, 4513, 4533, 4557, 4628, 5274, 5275, 5277, 5279, 5281, 5283, 5285, 5392, 5643, 6365, 6978, 6981, 6982, 6986, 6997, 7012, 7013, 7029, 7031, 7083, 7087, 7094, 7179, 7186, 7270
- Fast-Track Process, 7162
- fatty acids, 231, 1430, 2105, 2120, 2124, 2134, 2143, 2156, 2180, 3330, 3431, 4627, 4629, 4703, 5253, 5257, 5261, 5262, 5266, 5267, 5270, 5271, 5273, 5274, 5275, 5276, 5277, 5278, 5279, 5280, 5282, 5283, 5284, 5319, 5367, 5371, 5393, 5423, 5424, 5425, 5426, 5427, 5429, 5950, 5972, 6192, 6357, 6361, 6699, 6702, 6867, 6978, 7013, 7015, 7016, 7021, 7127, 7173, 7179, 7192, 7193
- fatty liver, 154, 160, 2910, 2998, 3033, 5248, 5261, 5262, 5263, 5264, 5266, 5271, 5272, 5273, 5274, 5276, 5277, 5278, 5280, 5281, 5282, 5283, 5285, 5298, 5299, 5300, 5334, 5340, 5341, 5343, 5344, 5347, 5348, 5352, 5354, 5355, 5357, 5358, 5361, 5362, 5363, 5365, 5366, 5367, 5371, 5372, 5374, 5375, 5379, 5381, 5383, 5384, 5385, 5388, 5389, 5396, 5400, 5410, 5411, 5413, 5418, 5424, 5427, 5428, 5429, 5430, 6630, 6633, 6704, 6992, 7180, 7184, 7186, 7197, 7199, 7201
- felines develop an, 3432
- femoral artery, 2280, 2285, 2286, 2344, 2818, 2819, 3171, 3381, 3382, 3384, 3385, 3386, 3395, 3677, 3692, 3693, 3751, 4190, 4195, 4203, 4728, 4739, 4743, 4744, 4745, 4788, 4796, 4799, 4812, 4819, 4820, 4823, 4825, 4826, 4863, 4872, 4873, 4879, 4884, 4885, 4893, 4894, 4895, 4897, 4913, 4921, 4922, 4932, 4988, 4989, 4995, 4996, 5004, 6151, 6152, 6217, 6488, 6491, 6493, 6521, 6529, 6558, 6566, 6729, 6731, 6732, 6733, 6734, 6736, 6737, 6743, 6745, 6750, 6754, 6762, 6765, 6766, 6779, 6789, 6792, 6794, 6797, 6853
- femoral head resection, 5867, 5868, 5869, 5878, 5879
- femoral sheath, 6732
- femorofemoral cross over bypass, 4825, 4826, 4838
- femoropedal bypass, 4895
- femtosecond laser, 1709, 1710, 1711, 1712, 1713, 1714, 1715, 1717, 1718, 1719, 1720
- femtosecond-laser-assisted cataract surgery, 1716
- fertility, 253, 256, 261, 262, 1600, 3431, 3696, 3709, 4412, 4413, 4432, 4481, 4486, 4487, 4492, 4493, 4494, 4497, 5990, 6029, 6030, 6036, 6037, 6038, 6039, 6040, 6042, 7117, 7123
- fever, 143, 776, 777, 779, 806, 997, 1045, 1096, 1097, 1102, 1451, 1571, 1573, 2055, 2057, 2061, 2431, 2464, 2473, 2484, 2491, 2495, 2742, 2799, 2812, 2926, 3164, 3168, 3195, 3267, 3306, 3318, 3319, 3328, 3330, 3401, 3812, 3815, 3818, 3833, 3878, 3889, 3896, 3900, 3904, 3910, 3913, 4329, 4566, 4612, 4986, 5435, 5558, 5568, 5618, 5625, 5702, 5703, 5706, 5911, 5957, 5960, 6011, 6012, 6182, 6192, 6641, 6660, 6995, 6996, 6999, 7258
- fibrin, 141, 364, 365, 374, 393, 407, 408, 409, 410, 411, 412, 413, 418, 419, 906, 907, 909, 1436, 1437, 1519, 1746, 2426, 2444, 2445, 2452, 2754, 2809, 2814, 3011, 3020, 3342, 3541, 3543, 3546, 3548, 3551, 3560, 3566, 3568, 3571, 3572, 3579, 3614, 3889, 4213, 4246, 4250, 4251, 4256, 4357, 4548, 4674, 4876, 5002, 5468, 5918, 5923, 5927, 5960, 6011, 6104, 6137, 6142, 6205, 6421, 6428, 6997, 7328, 7329, 7331
- fibrinogen, 172, 413, 414, 1437, 2445, 2801, 3011, 3020, 3076, 3078, 3079, 3080, 3098, 3099, 3103, 3110, 3560, 3614, 3776, 3866, 4357, 4506, 4876, 4956, 5463, 5465, 5466, 5467, 5468, 5469, 5918, 5923, 5926, 5927, 6704, 7212, 7260, 7264, 7328
- fibroblast growth factor, 99, 100, 615, 2186, 3020, 3538, 3543, 3547, 3555, 3558, 3559, 3561, 3566, 3579, 3704, 3734, 5352, 6413, 6984
- fibroblasts, 564, 905, 906, 910, 1433, 1734, 1736, 2105, 2111, 2414, 2965, 2993, 2994, 3011, 3012, 3544, 3545, 3548, 3560, 3561, 3570, 3643, 3656, 4675, 5659, 6411, 6413, 6415, 6416, 6417, 6418, 6426, 6427, 6428, 7119, 7121
- fibrocartilage, 3010, 3358, 3540, 3542, 3544, 3546, 3548, 3561, 3562, 6230
- fibroids, 4471, 4484, 4485, 4486, 4487, 4496, 7118, 7119, 7123
- fibromuscular dysplasia, 1351, 4814, 4842, 4853, 4876, 4902
- fibrostenotic, 5950, 5951, 6007
- fibrous dysplasia, 31, 43, 47, 5515, 5516, 5522, 5523, 5529, 5530, 5533, 5534, 5535, 5536
- Finney, 5954, 5964, 5965, 5966, 5967, 5968
- first assistant, 1562, 1563, 4407, 5018, 5021, 5033, 5036, 5037, 5038, 5039, 5040, 5066, 5068, 5072, 5144, 5184, 5187, 5188, 5190, 5191, 5239, 6458
- Fisher and Veronesi, 1579

- fistulae, 221, 1429, 1433, 1434, 1440, 1639, 1644, 1648, 1656, 1663, 1706, 1738, 1918, 1984, 1991, 2018, 2073, 2085, 2086, 2093, 2097, 2098, 2106, 2442, 2445, 2449, 3189, 4394, 4744, 4922, 4968, 4969, 4970, 4971, 4981, 4985, 5000, 5011, 5955, 5956, 5957, 5958, 5959, 5960, 5975, 5995, 6001, 6006, 6007, 6012, 6013, 6015
- fistulogram, 2061, 6013
- fixed combinations of a prostaglandin analogue, 6887
- flap failure, 2601, 2608, 2612, 2635, 2639, 2643, 2657, 5435, 5439
- flexible intramedullary bioactive coating, 69
- flexible intramedullary nailing, 1, 26, 29, 30, 48, 49, 74, 75, 76, 78, 80, 83, 87, 88, 95
- flexible LMA, 2463, 2465
- floating craniotomies, 4056
- FLOW 800, 1631, 1632, 1633, 1634, 1635, 1637, 1638, 1639, 1640, 1641, 1642, 1643, 1645, 1646, 1647, 1649, 1651, 1659, 1662, 1663
- flow cytometry, 2926, 2939, 2941, 2957, 2959, 2960, 2961, 3446, 3739, 7217
- flow diverter, 945, 950, 951, 952, 953, 955, 956
- flow rates, 972, 985, 2656, 3049, 3052, 3214, 3274, 3455, 3456, 3495, 3498, 3523, 6596
- fluid therapy, 975, 1445, 1461, 2710, 2718, 3277, 3278, 3297, 3313, 3314, 3317, 3318, 3319, 3323, 3329, 3330, 3332, 3333, 3334, 3385, 4564, 4654, 4660, 7090, 7093
- fluid-structure interactions, 3461, 3472
- fluorescence-guided surgery, 689, 710, 3338, 3353, 3369, 3373
- fluoroscopic guidance, 323, 1950, 1959, 1963, 1968, 1978, 1979, 1992, 1994, 2019, 2215, 4486, 5782, 5961, 6641, 6750
- fluoroscopic, 267, 322, 325, 706, 726, 782, 784, 1236, 1327, 1772, 1866, 1944, 1950, 1959, 1963, 1966, 1968, 1978, 1979, 1992, 1994, 2014, 2016, 2018, 2019, 2051, 2071, 2212, 2215, 2216, 2221, 2224, 2225, 2260, 2265, 2272, 2282, 4486, 5782, 5961, 6125, 6641, 6750
- fluoroscopy, 322, 346, 646, 705, 706, 717, 726, 782, 783, 1297, 1328, 1335, 1336, 1346, 1655, 1770, 1854, 1932, 1943, 1950, 1954, 1955, 1958, 1960, 1966, 1967, 1977, 1978, 1979, 1980, 1983, 1984, 1990, 1991, 1992, 1993, 1994, 1997, 1998, 2001, 2002, 2003, 2005, 2006, 2007, 2013, 2014, 2015, 2017, 2080, 2095, 2096, 2211, 2212, 2213, 2214, 2215, 2217, 2218, 2219, 2221, 2222, 2223, 2224, 2225, 2260, 2271, 2282, 2344, 3137, 3156, 3361, 4190, 6110, 6126, 6179, 6208, 6209, 6210, 6211, 6268, 6539, 6613, 6655
- focused parathyroidectomy, 7051, 7052, 7054, 7056
- folate, 147, 222, 224, 226, 231, 256, 258, 259, 3404, 6352, 6362, 6363, 6371, 6884, 7251, 7254
- follow-up support, 2689, 2692, 2697, 2698
- Fontaine classification, 4815, 4816, 4880
- foregut, 1296, 1311, 1866, 1885, 1895, 1950, 1953, 1996, 2142, 2144, 2147, 2154, 2176, 2729, 2731, 4183, 5939, 5940, 5941, 5942, 5944, 5945, 6983
- formats, 2277, 3235, 3340, 6326, 6328, 6329, 6336
- Fountain classification, 4815
- Fourier, 1717, 3090, 3093, 3817
- fracture healing, 72, 74, 3349, 3557, 3558, 3559, 3560, 3561, 3562, 3565, 3567, 3568, 3570, 3571, 3574, 3575, 3576, 3577, 3578, 3579, 3580, 3581, 5606, 6230, 6231, 6234, 7123
- free air, 1092, 1098, 1099, 2058, 2059, 2073, 5962
- free flap, 1405, 1406, 1408, 1410, 1411, 1412, 1413, 1417, 1419, 1421, 1422, 1424, 1426, 1427, 1734, 2560, 2562, 2587, 2591, 2592, 2594, 2597, 2601, 2604, 2607, 2608, 2609, 2611, 2612, 2613, 2614, 2635, 2636, 2637, 2639, 2640, 2641, 2642, 2643, 2644, 2646, 2647, 2648, 2650, 2651, 2657, 2658, 2662, 2663, 2665, 2673, 2675, 4043, 4449, 5432, 5433, 5440, 5515, 6158
- frontal encephaloceles, 4017
- frontal lifting, 6446
- fronto-orbital bandeau, 4024
- frozen elephant trunk, 4771, 4774
- Full Outline of UnResponsiveness (FOUR) Score, 3879
- functional anatomy, 276, 885, 1666, 2872, 3406
- functional capillary density, 3073, 3084, 3086, 3088
- functional free muscle transfer, 1670
- functional rhinoplasty, 439, 446, 447, 449, 637, 1535, 1536
- fundamental anatomic, 3432
- fundic gland polyps, 1339, 1894
- fundoplication, 1896, 2791, 4184, 4580, 5078, 6401
- futility, 1611, 4098, 4101, 4105, 4107, 4117, 6860
- future laparoscopy, 2762
- future lingual tonsil hypertrophy, 2543

G

- gait analysis, 1761, 1779, 1780, 1781, 1782, 1786, 1788, 1790, 1791, 1792, 1793, 1794, 1796, 1797, 1799, 1800, 1801, 1802, 1803, 1805, 1808, 1809, 1810, 1811, 1812, 1813, 6261
- gastric acidity, 2047, 2053, 4580
- gastric bypass surgery, 147, 155, 156, 157, 161, 198, 206, 224, 231, 232, 249, 250, 251, 265, 771, 795, 796, 839, 841, 1505, 2006, 2103, 2105, 2106, 2113, 2114, 2115, 2132, 2133, 2134, 2137, 2148, 2155, 2156, 2158, 2159, 2160, 2161, 2163, 2165,

- 2166, 2167, 2168, 2169, 2171, 2172, 2184, 2185, 2186, 2701, 2724, 2726, 2731, 2745, 2746, 2747, 4305, 4306, 4508, 4535, 4541, 4543, 4601, 4609, 5411, 6352, 6354, 6355, 6358, 6360, 6361, 6363, 6368, 6370, 6979, 6980, 6983, 6988, 6991, 7002, 7018, 7027, 7028, 7030, 7033, 7034, 7129, 7147, 7150, 7198, 7203, 7204, 7205, 7229, 7254, 7266
- gastric outlet obstruction, 149, 1329, 1332, 1337, 1338, 1852, 1858, 1893, 1903, 1904, 1908, 1947, 1957, 1962, 1969, 1999, 2000, 2010, 2018, 2021, 2024, 5950, 5952
- gastric plication, 801, 806, 820, 2831, 2832, 2833, 2834, 2836, 2837
- gastric stenosis, 2683, 2684, 2687, 2688
- gastric twist, 2683, 2684, 2687
- gastric ulceration, 259, 2047, 2091
- gastric ulcers, 1896, 1897, 2067
- gastric varices, 1303, 1891, 1892, 1903
- gastritis, 221, 222, 791, 792, 1038, 1328, 1334, 1888, 1890, 1891, 1894, 2067, 2733, 2735, 4564, 4580, 4840, 5203, 5618
- gastrocolic fistula, 819, 2093, 2094, 2101
- gastrocutaneous fistula, 2032, 2036, 2073, 2098, 2101
- gastroesophageal reflux disease, 153, 160, 761, 797, 841, 1296, 1308, 1309, 1314, 1450, 1682, 1686, 1766, 1767, 1885, 1895, 1904, 2700, 2742, 2747, 2763, 4171, 4569, 4570, 4573, 4575, 4580, 4582, 4583, 4584, 4585, 5063, 5084, 5086, 5181, 5230, 5360, 5512, 7003, 7251
- gastroesophageal reflux, 150, 153, 160, 256, 761, 797, 841, 1296, 1308, 1309, 1314, 1320, 1450, 1682, 1686, 1766, 1767, 1838, 1885, 1895, 1904, 2700, 2742, 2747, 2763, 3402, 4171, 4560, 4569, 4570, 4573, 4575, 4580, 4582, 4583, 4584, 4585, 5063, 5084, 5086, 5181, 5214, 5230, 5360, 5510, 5512, 5513, 5940, 5943, 5964, 7003, 7251, 7257
- gastrointestinal stromal tumors, 1897, 1904
- gastrointestinal T-anchor(s), 1916, 1934, 1935, 1936, 1937, 1939, 1940, 1958, 1985, 1997, 1998, 2001, 2002, 2003, 2013, 2014, 2017, 2026, 2027, 2040, 2097, 2100
- gastrojejunal anastomosis, 139, 144, 147, 816, 845, 847, 849, 856, 1996, 1999, 2000, 2002, 2733, 2743, 4573, 4606, 5095, 5097, 5114, 5141, 5142, 5161, 5244, 5245, 6409, 6998, 7000, 7002, 7005
- gastro-jejunostomy, 1948, 2022, 5164, 5177, 5943, 5950
- gastroparesis, 983, 1045, 1834, 1898, 1899, 1900, 1904, 1905, 1922, 1924, 1947, 1948, 1951, 1957, 1962, 1970, 2009, 2011, 2020, 2023, 3390, 4556, 4560, 4562
- gastropexy, 1832, 1855, 1934, 1936, 1937, 1938, 1939, 1940, 1941, 1943, 1958, 1984, 1990, 1997, 2006, 2009, 2012, 2013, 2014, 2015, 2020, 2021, 2046, 2049, 2051, 2052, 2097, 2099
- GCS motor, 3804, 3855, 3856, 4083, 4125, 4126, 4127, 4131, 4134, 4136
- gender dysphoria, 1605, 6154, 6158
- gender reassignment surgery, 1600, 6149, 6151, 6157
- gene gun, 3115, 3116, 3117, 3118, 3119, 3120, 3121, 3122, 3127, 3128
- gene therapy, 1729, 1730, 3015, 3023, 3063, 3115, 3120, 3121, 3122, 3124, 3127, 3128, 3365, 3368, 3370, 3515, 3543, 3569, 3759, 3760, 6596
- general surgery, 728, 1464, 2670, 2761, 2764, 3243, 3667, 3929, 4292, 4469, 4709, 4710, 5165, 5794, 6328, 6393, 6396, 6407, 6408, 6454, 6759
- generalities, 2339
- genital reconstructive surgery, 6147
- genomic post-conditioning, 3791
- genomic, 2351, 2352, 2962, 3021, 3432, 3791, 5640, 5651, 5687, 5699
- German phase model, 1036
- ghrelin, 170, 171, 172, 173, 181, 183, 184, 758, 830, 871, 2004, 2121, 2131, 2140, 2141, 2142, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2176, 2177, 2181, 2182, 2184, 2185, 2678, 2679, 2680, 2681, 2689, 2697, 2702, 2704, 2705, 2714, 2723, 2730, 2731, 2732, 2745, 2775, 2831, 2832, 2833, 2834, 3710, 4509, 4557, 4559, 5271, 5361, 5371
- ghrelin, 6979, 6982, 7012, 7016, 7018, 7026, 7027, 7028, 7029, 7031, 7033, 7034, 7203, 7227, 7228, 7267
- giant cell tumor of the bone, 5732
- giant hemangioma, 5751, 5752, 5754, 5756
- glandular section, 2834, 2835
- Glasgow Coma Scale, 921, 922, 932, 992, 1525, 2796, 3784, 3786, 3836, 3843, 3854, 3879, 3910, 3919, 3940, 3942, 3953, 3960, 3972, 3978, 3998, 4018, 4094, 4103, 4112, 4120, 4123, 4129
- Glasgow Coma Scale score, 3784, 3843, 3919, 3940, 3942, 3972, 3978
- Glasgow Outcome Scale, 924, 1029, 1064, 3786, 3818, 3840, 3842, 3843, 3845, 3960, 3968, 3973, 3979, 3982, 3989, 3996, 4047, 4110, 4111, 4123, 4131
- Glasgow Outcome Score, 883, 921, 924, 1059, 1065, 3855, 4025, 4038, 4091, 4095, 4129
- glial cells, 967, 1163, 3767, 3782, 4556, 4851

- gliomas, 1161, 1162, 1164, 1165, 1169, 1186, 1188, 1189, 1635, 1636, 1639, 1640, 1643, 1646, 1647, 1692, 1693, 1694, 1706, 7097, 7098, 7113, 7114
- Glissonian approach, 2341, 2342
- Glucagon, 172, 2115, 2146, 2147, 2148, 2156, 2161, 2165, 2168, 2732, 2745, 5281, 6981, 6989
- glucagon-like peptide - 1 (GLP - 1), 6979
- glucagon-like peptide 2 (GLP2), 6981
- glucagon-like-polypeptide (GLP-1), 2731
- glutamate, 994, 3032, 3703, 3767, 3775, 3782, 3784, 3786, 3787, 3788, 3794, 3797, 3814, 3816, 3820, 3837, 3841, 3844, 3846, 3854, 4096, 5612, 7210, 7211, 7218, 7219
- glyburide, 3773, 3779, 3942, 3946
- glycolysis, 1163, 1488, 3322, 3513, 3529, 3674, 3782, 3783, 3785, 3787, 3837, 5278, 5281, 7211
- glycosaminoglycan, 3012, 3541, 3566, 3573
- goat, 3007, 3111, 3358, 3432, 3542, 3544, 3557, 7030
- gold-standard, 1082, 1083, 2991, 4384, 5301, 5332, 6655
- good laboratory practice, 3202, 3210, 3232, 3428, 3434, 3439
- Gott shunt, 4797, 4798, 4803
- Göttingen minipig, 3388, 3406, 3537, 3542
- gracilis muscle flap, 1672
- grading scales, 924, 931, 938, 992
- gradual rewarming, 3050, 3496, 3509, 3524, 3525, 3899
- graft-versus-host (GVH) responses, 2915
- granuloma formation, 566, 571, 578, 6182
- granulomas, 391, 566, 571, 578, 2406, 5940, 5942, 6211
- gravitational valve, 1019, 1022, 1025
- groin flap, 2562, 5431, 5432, 5433, 5434, 5435, 5436, 5437, 5438, 5439, 5440, 6159
- growth and differentiation factor, 1736, 3558, 3566, 3569
- growth differentiation factor, 3538, 3543, 3549
- growth factors, 74, 615, 1437, 1732, 1735, 1737, 1747, 2899, 2919, 2995, 3011, 3025, 3052, 3498, 3537, 3538, 3539, 3541, 3542, 3543, 3546, 3559, 3561, 3562, 3563, 3568, 3570, 3574, 3682, 3751, 4001, 4889, 5923, 6010, 6019, 6279, 6303, 6411, 6413, 6415, 6416, 6417, 6418, 6419, 6420, 6428, 7120
- g-tube, 1931, 1932, 1933, 1938, 1943, 1944, 1969, 2000
- guided bone regeneration, 1730, 1734, 1748, 1749, 1750, 1751, 1752
- guided tissue regeneration, 1729, 1730, 1731, 1749, 1750, 1751, 1752
- guidewire(s), 334, 882, 1834, 1911, 1912, 1913, 1914, 1921, 1926, 1927, 1933, 1937, 1938, 1941, 1942, 1950, 1959, 1962, 1963, 1964, 1965, 1966, 1968, 1977, 1978, 1979, 1980, 1986, 1992, 1997, 2003, 2018, 2043, 2045, 2067, 2080, 2085, 2094, 2095, 2099, 2100, 4203, 4959, 6493, 6617, 6655, 6722, 6745, 6779, 6793, 6833

- health help-seeking behavior, 7133, 7142, 7146
- heart and lung transplantation, 3611, 7274
- heart failure, 142, 143, 164, 176, 179, 253, 520, 973, 1038, 1508, 1769, 1857, 1863, 1872, 1881, 2126, 2825, 2839, 2840, 2846, 2850, 2854, 2859, 3315, 3317, 3379, 3381, 3464, 3474, 3629, 3666, 3672, 3684, 3705, 3708, 3864, 4214, 4528, 4529, 4784, 4788, 4789, 4790, 4834, 4836, 4878, 4922, 4941, 4943, 4944, 4955, 4977, 4978, 5854, 5892, 5912, 5918, 6138, 6217, 6618, 6619, 6719, 6773, 6774, 6826, 6827, 6831, 6860, 6861, 7000, 7212, 7233
- heart machine preservation, 3060
- heart models, 3244, 3452, 3474
- heart transplantation, 3023, 3029, 3036, 3042, 3044, 3059, 3123, 3425, 3477, 3586, 3587, 3588, 3589, 3590, 3598, 3599, 3600, 3601, 3604, 3605, 3606, 3607, 3608, 3627, 3628, 3629, 3639, 3642, 3643, 3644, 3650, 3663, 5926, 7273
- Heineke-Mikulicz, 5944, 5964, 5965, 5966
- hemangioma-like vessels, 5751, 5752, 5753, 5754, 5755
- hemangiomas, 267, 1096, 1168, 1183, 1219, 1698, 1707, 5751, 5754, 5755
- hematemesis, 144, 148, 777, 1334, 2067, 2091, 2742, 3865, 6654, 6997
- hematocrit, 141, 172, 2638, 2896, 3074, 3076, 3077, 3080, 3081, 3084, 3097, 3098, 3276, 4786, 4888, 4939, 4982, 5464, 5467, 5633, 5655, 5703, 5790, 5792, 5913, 5914, 5915, 5918, 5926, 5931, 5933, 5934, 5970
- hematogenous spread, 2354, 4947, 6278, 6301, 6302
- hematopoietic stem cells, 3263, 3442, 3558, 3560, 3571, 5628, 5653, 5654, 5661
- hemedex, 3806
- hemodynamic stability, 1445, 1448, 1449, 2066, 3891, 6998, 7164, 7274
- hemorheology, 2821, 2824, 3073, 3102, 3103, 3105, 3106, 3111, 3112
- hemorrhagic stroke, 916, 3773, 3779, 3788, 3818, 3819, 3851, 4073, 4078, 5000
- hemorrhagic, 47, 916, 1015, 1149, 1178, 1179, 1180, 1182, 1190, 1213, 1215, 1243, 1255, 1284, 1611, 1626, 2110, 2495, 2820, 2894, 2896, 2906, 2911, 2913, 2968, 2974, 3084, 3104, 3107, 3108, 3111, 3682, 3683, 3684, 3703, 3767, 3771, 3773, 3779, 3788, 3818, 3819, 3822, 3851, 3853, 3861, 3864, 3868, 3872, 3903, 3918, 3984, 4039, 4048, 4053, 4073, 4078, 4083, 4084, 4087, 4088, 4089, 4125, 4135, 4136, 4479, 4480, 4549, 4550, 4553, 4580, 4766, 4826, 4843, 4931, 4982, 5000, 5643, 5648, 5685, 5728, 5783, 5795, 5954
- hepatectomy technique, 2866
- hepatic artery aneurysms, 4844
- hepatic encephalopathy, 3756, 3865, 3866, 3872, 3873, 6139
- hepatic metastases, 1271, 1272, 1278, 1593, 1595, 1597, 2375, 2880, 2910, 3509, 3527, 3528, 6301, 6302, 6303, 6304, 6309, 6316, 6324
- hepatic resection, 704, 716, 1224, 1504, 1505, 1587, 1588, 1589, 1590, 1597, 1598, 2334, 2335, 2336, 2337, 2338, 2345, 2346, 2350, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2373, 2374, 2375, 2873, 2874, 2878, 2880, 2881, 2882, 2912, 4262, 5811, 5816, 6287, 6301, 6302, 6304, 6305, 6309, 6310, 6311, 6312, 6315, 6317, 6319, 6321, 6322, 6323, 6623, 6624, 6625, 6626, 6627, 6629, 6631, 6632, 6633, 6637, 6643, 6646, 6647, 6648, 6650, 6651, 6657, 6662, 6905
- hepatocellular-steatosis, 5287
- hepatocyte transplantation (HTx), 3747
- hepatocyte, 1226, 2886, 2891, 2907, 2908, 2964, 2988, 2989, 3002, 3003, 3034, 3057, 3593, 3594, 3745, 3746, 3747, 3748, 3749, 3750, 3751, 3753, 3754, 3755, 3756, 3757, 3758, 3759, 3760, 3761, 3762, 3763, 3866, 5248, 5251, 5253, 5254, 5255, 5256, 5258, 5260, 5261, 5262, 5284, 5288, 5289, 5294, 5318, 5346, 5351, 5352, 5358, 5359, 5367, 5391, 5421, 5423, 5424, 5425, 5800, 6416, 6622, 6624, 6628, 6630, 6641, 6651
- hepatopancreatobiliary surgery, 2866
- hepatosplenomegaly, 1866, 1987, 2069, 5702
- herniation, 259, 260, 547, 556, 586, 720, 779, 780, 782, 783, 784, 785, 787, 792, 793, 800, 802, 807, 824, 833, 948, 1044, 1170, 1305, 1721, 2013, 2014, 2018, 2020, 2239, 2593, 2752, 2763, 3268, 3539, 3766, 3772, 3773, 3801, 3804, 3819, 3836, 3837, 3839, 3852, 3856, 3861, 3863, 3864, 3866, 3878, 3879, 3880, 3890, 3903, 3932, 3939, 3940, 3941, 3942, 3953, 3954, 3958, 3980, 3991, 3995, 3996, 3999, 4002, 4003, 4016, 4018, 4024, 4025, 4036, 4037, 4038, 4042, 4046, 4049, 4050, 4082,

- 4127, 4129, 4131, 4245, 4376, 4598, 4599, 4602, 4606, 5382, 5573, 5594, 5968, 6206, 7314
- heterotopic abdominal heart transplantation, 3587, 3588, 3627, 3637
- hiatal hernia(s), 150, 158, 760, 761, 780, 782, 785, 787, 792, 793, 797, 806, 809, 824, 841, 1296, 1308, 1320, 1450, 1866, 1887, 1888, 1902, 1918, 1984, 2012, 2014, 2018, 2019, 2024, 2069, 2684, 2736, 2752, 2776, 4184, 4295, 4313, 4575, 4576, 4577, 4578, 4584, 5019, 5068, 5089, 5152, 5181, 7004
- high dose barbiturates, 3898, 3899
- high income countries, 4055, 4056
- high-grade invasive transitional cell carcinoma, 3432
- high-grade sarcoma, 5721, 5722, 5725, 5726, 5727, 5728
- high-order models, 3449, 3450, 3460, 3462, 3471, 3473
- hinge craniectomy, 4023
- hip arthroplasty, 732, 733, 1456, 1575, 1670, 2275, 2276, 2282, 2283, 2290, 2291, 2295, 2307, 2308, 2309, 2319, 3134, 4621, 5874, 5880
- hip dislocation, 1815, 1816, 1820, 1824, 1825, 1826, 1827, 1828, 2196, 2197, 2242, 2285, 5867, 5868, 5869, 5870, 5879, 6241
- hip dysplasia, 1819, 1829, 2242, 2245, 2258, 2263, 2276, 6958, 6959, 6963
- hip fractures, 287, 2209, 2210, 6239, 6244, 6245, 6247, 6248, 6249, 7155
- hip fusion, 5868, 5869, 5876, 5878, 5880
- hip imaging, 2212, 2227
- hip oncology, 2312
- hip reconstruction, 1815, 1816, 1817, 1823, 1824, 1825, 1826, 1827, 1828
- hip revision arthroplasty, 2293
- hip surgery, 1447, 1824, 1826, 1830, 2189, 2211, 2249, 2265, 2271, 2275, 2293, 2294, 2300, 2308, 2309, 5878, 5879, 5880, 6243, 6246
- hiperglycemia, 4653
- histology, 4, 347, 478, 555, 576, 905, 1140, 1160, 1267, 1339, 1530, 1700, 1723, 1725, 1726, 1748, 1890, 1895, 2397, 2459, 2891, 2896, 2928, 3037, 3054, 3056, 3057, 3058, 3060, 3268, 3357, 3358, 3366, 3371, 3526, 3557, 3563, 4141, 4159, 4343, 4407, 4412, 4491, 5247, 5269, 5287, 5301, 5330, 5334, 5347, 5351, 5354, 5359, 5360, 5361, 5368, 5370, 5372, 5375, 5376, 5383, 5396, 5410, 5479, 5523, 5639, 5701, 5702, 5738, 5804, 5841, 5858, 5863, 5864, 5865, 5942, 6056, 6310, 6316, 6426, 6595, 6598, 6603, 6633, 7197
- histopathological techniques, 2850, 3573
- histopathology, 515, 1187, 1188, 1583, 2458, 2460, 2580, 3356, 3707, 4137, 4867, 5287, 5298, 5300, 5301, 5453, 5651, 5683, 5699, 5701, 5702, 5703, 5704, 5721, 5728, 5732, 5738
- hollow viscus injury, 2055, 2057, 2058
- HOPES trial, 3818
- horizontal partial laryngectomy, 6965, 6966, 6967
- hormonal study, 5086
- host-versus-graft, 2915, 2916, 2931
- HPB anatomy, 2865
- HPB models, 2865
- HPB research, 2865
- human diseases, 349, 2865, 2921, 2967, 3073, 3209, 3337, 3375, 3401, 3428, 3429, 3430, 3446, 3557
- Hürthle cell adenoma, 5676, 5688
- Hürthle cell tumor, 5676, 5685, 5687, 5688
- Hürthle cell, 5675, 5676, 5678, 5679, 5682, 5684, 5685, 5687, 5688
- husbandry, 2977, 3248, 3259, 3260, 3265, 3266, 3267, 3290, 3291, 3292, 3419, 3434, 3439
- hyaline cartilage, 2228, 2236, 2238, 3537, 3538, 3544, 3545, 3546, 3549, 3555
- hyaluronic acid, 557, 559, 561, 562, 569, 570, 572, 574, 575, 576, 577, 578, 618, 627, 1378, 2533, 2539, 2625, 3054, 3056, 3057, 3538, 3539, 3543, 3545, 3558, 3562, 3566, 3572, 3576, 5353, 5354, 5366, 6420
- hybrid procedure, 700, 4211, 4897
- hydrocephalus, 897, 898, 927, 931, 932, 934, 937, 938, 942, 943, 944, 958, 959, 964, 972, 1019, 1021, 1022, 1023, 1024, 1025, 1037, 1038, 1043, 1044, 1053, 1065, 1169, 1180, 1615, 1618, 3395, 3396, 3771, 3779, 3818, 3819, 3820, 3852, 3861, 3862, 3863, 3900, 3903, 3905, 3914, 3940, 3952, 3953, 3969, 3984, 3998, 4000, 4025, 4034, 4036, 4072, 4085, 4087, 4088, 4089, 6118
- hydrodynamic method, 3115, 3123, 3125
- hydrogel, 478, 479, 492, 1433, 2047, 2053, 3545, 3546, 3551, 3562, 3565, 3569, 3571, 3572, 3577, 3580, 3727, 3728, 3730, 3741, 6424, 6426
- hydrogen peroxide, 1969, 2031, 3790, 4676, 4684, 4712, 5252, 6418, 6428, 7126
- hydrosalpinx, 4479, 6029, 6036, 6038, 6039
- hydroxyapatite, 7, 8, 10, 11, 12, 70, 71, 72, 75, 76, 79, 86, 87, 92, 102, 324, 559, 565, 572, 576, 618, 620, 2284, 2324, 2331, 2332, 2625, 3353, 3558, 3559, 3563, 3566, 3569, 3572, 3573, 3579, 5528, 6227
- hyoid suspension, 1535
- hyonatraemia, 3317
- hyperchloremia, 3319, 3321, 3325, 3326, 3334
- hyperchloremic metabolic acidosis, 3320, 3325, 3326, 3333

- hyperemia, 127, 1769, 3766, 3767, 3777, 3807, 3809, 3812, 3839, 3842, 3992, 4082, 5459, 5488, 5490, 5952, 6205
- hyperkalemia, 3033, 3319, 3320, 3325, 3334, 3859, 3897, 7088
- hypermagnesemia, 3323
- hypermetabolism, 1772, 1773, 3814
- hypernatraemia, 3318
- hyperosmolar therapy, 3809, 3861, 3864, 3867, 3897, 3898, 3993
- hyperoxia, 2824, 3790, 3797, 3798, 3814, 3827, 3830, 4654
- hyperphosphatemia, 3322, 3334, 7088
- hyperplastic polyps, 1332, 1894
- hyperthermia, 1038, 3400, 3839, 3876, 3878, 3891, 3896, 3909, 3935, 5000, 6913, 6915, 6916, 7082, 7089, 7103, 7277, 7285, 7286
- hypertrophic cartilage, 3544, 3574
- hypertrophic differentiation, 3540, 3541, 3543, 3544
- hypertrophy, 165, 178, 241, 385, 426, 445, 496, 498, 506, 510, 514, 557, 1194, 1229, 1328, 1348, 1349, 1493, 1496, 1507, 1536, 1537, 1538, 1540, 1543, 1548, 1550, 1554, 1555, 1681, 1682, 1683, 1686, 1687, 1691, 1701, 2115, 2163, 2234, 2240, 2431, 2457, 2469, 2472, 2488, 2489, 2495, 2496, 2507, 2514, 2516, 2519, 2540, 2548, 2840, 2845, 2846, 2853, 2859, 2863, 3545, 3549, 3554, 4529, 4788, 4790, 5253, 5510, 5825, 5910, 5914, 6163, 6469, 6623, 6625, 6631, 6633, 6640, 6642, 6643, 6644, 6645, 6647, 6648, 6651, 6978, 6984, 6989, 7084
- hyperventilation, 958, 3326, 3328, 3777, 3807, 3811, 3825, 3827, 3859, 3866, 3870, 3891, 3894, 3898, 3899, 3900, 3936, 3958, 3963, 3967, 3970, 3972, 3976, 3993, 4096, 4104, 4105, 4979
- hypoalbuminemia, 224, 225, 232, 862, 4624, 4630, 5377, 5378, 5380, 5381, 5382, 5392, 5950
- hypochloremia, 3318
- hypodensity, 1173, 3820, 3933, 3935, 3937
- hypofibrinogenemia, 5463, 5468
- hypogastric plexus, 4425, 4426, 4428, 4999
- hypoglossal nerve, 1550, 1551, 1557, 1666, 1667, 1668, 1669, 7323
- hypokalemia, 3319, 3325, 3330, 3331, 3333, 3334, 5647, 5983
- hypomagnesemia, 989, 3320, 3322, 3323, 7285
- hyponatremia, 971, 977, 3317, 3332, 3333, 3334, 3864, 3898, 4785, 6131
- hypopharyngeal surgery, 1533, 1535, 1547
- hypophosphatemia, 91, 100, 3322, 3331, 3334
- hypothermic liver perfusion, 3070
- hypothermic machine perfusion, 3043, 3045, 3046, 3053, 3063, 3064, 3065, 3066, 3067, 3069, 3070, 3479, 3480, 3488, 3502, 3503, 3504, 3505, 3506, 3509, 3510, 3520, 3527, 3528, 3529, 3530, 3532, 3533, 3534
- hypovolemia, 1100, 1102, 1350, 1529, 2640, 2663, 2896, 3099, 3315, 4660, 4661, 4979, 4980, 5791, 6137, 6216, 7083
- hysterectomy classes, 4413
- hysterectomy, 714, 1454, 1600, 1603, 1604, 2715, 3134, 3136, 3145, 3150, 3151, 3153, 3154, 3155, 4367, 4368, 4371, 4376, 4377, 4379, 4380, 4386, 4389, 4390, 4391, 4392, 4395, 4398, 4399, 4400, 4402, 4403, 4405, 4407, 4408, 4410, 4412, 4413, 4422, 4423, 4425, 4430, 4432, 4433, 4434, 4435, 4436, 4437, 4438, 4439, 4440, 4441, 4442, 4444, 4445, 4472, 4474, 4477, 4478, 4484, 4486, 4488, 4493, 4495, 4496, 4497, 4567, 4614, 5792, 6029, 6035, 6036, 6037, 6038, 6042, 6043, 6148, 7118, 7119
- I
- iatrogenic crouch gait, 1788, 1794, 1801, 1802, 1803, 1804, 1806, 1807, 1808, 1809, 1810
- iatrogenic vascular injuries, 4911
- ICP monitoring, , 992, 1020, 3771, 3801, 3802, 3803, 3804, 3805, 3812, 3813, 3815, 3819, 3841, 3852, 3854, 3855, 3860, 3863, 3866, 3880, 3885, 3912, 3936, 3950, 3959, 3971, 3984, 3986, 4002, 4003, 4058, 4059, 4095
- ICP waveform, 3881, 3885, 3886, 3887, 3897
- IgG4-related sclerosing cholangitis, 6902, 6903, 6905, 6906, 6907, 6908, 6909, 6910, 6911
- IgG4-related sclerosing disease, 6902, 6909, 6910
- ileal pouch-anal anastomosis, 5981, 5990, 5992, 5998
- ileocecal valve, 221, 828, 843, 857, 1091, 1103, 1104, 2808, 2809, 2832, 4556, 4560, 5183, 5184, 5185, 5186, 5217, 5218, 5229, 5234, 5235, 5954, 5963, 6018, 6279
- ileorectal anastomosis, 5987, 5988, 5989, 5990, 5998, 6014
- ileus, 146, 997, 1092, 1094, 1854, 2009, 2010, 2020, 2230, 2709, 2799, 2804, 3143, 3860, 4318, 4330, 4347, 4376, 4408, 4419, 4555, 4556, 4558, 4559, 4560, 4561, 4562, 4563, 4564, 4565, 4566, 4567, 4568, 4637, 4638, 4639, 5742, 5968, 5986, 5998, 6012, 6014, 6310, 6314, 7230
- Iliac artery aneurysms, 4833
- Ilizarov apparatus, 121, 122, 123, 131, 132, 133, 134
- Ilizarov method, 2, 6, 7, 30, 46, 47, 48, 49, 67, 90, 99, 101, 122, 134
- image-based, 663, 683, 2320, 3449, 3477, 3592, 6534

- Image-guided interventions, 662, 708, 710
 image-guided surgery, 674, 676, 680, 681, 708, 1229, 2418, 6110
 imagery techniques, 3337
 immersed boundary, 3461, 3474, 3475, 3478, 5887
 immobility, 567, 3270, 3902, 3907, 4729, 5439, 5557, 6203, 6215, 6230, 6243
 immune tolerance, 3611, 3647, 3651, 3652, 3653, 3654, 3655
 immunologic, 1654, 2544, 2781, 2806, 2817, 2887, 3422, 3432, 3435, 3587, 3597, 3609, 3613, 3681, 5467, 6181, 7211
 immunostaining, 2987, 5291, 5326, 5327, 5328, 5329, 5628, 5641, 5693, 5697, 5698, 5701, 5702, 5703, 5705, 5706, 5707, 5708, 5745, 5769
 immunosuppressants, 2922, 3433, 3441, 3722, 5463, 5464, 5465, 5983, 5995, 6194
 immunosuppression, 1734, 1861, 1867, 2033, 2043, 2095, 2364, 2812, 2919, 2922, 2927, 2929, 2930, 2931, 2933, 2935, 2983, 2989, 2999, 3245, 3263, 3266, 3286, 3287, 3294, 3401, 3422, 3590, 3592, 3602, 3605, 3612, 3613, 3614, 3626, 3627, 3628, 3629, 3634, 3637, 3641, 3647, 3649, 3650, 3652, 3654, 3656, 3659, 3661, 3663, 3721, 3722, 3725, 3727, 3728, 3730, 3731, 3734, 3738, 3739, 3742, 3743, 3757, 3899, 4072, 4642, 4643, 4985, 5399, 5401, 5403, 5413, 5467, 5943, 5959, 5961, 6018
 immunosuppressive therapy, 3121, 3276, 3279, 3401, 3593, 3601, 3606, 3647, 3650, 3654, 3656, 3657, 4643, 5951, 5961, 6017
 immunosuppressive, 2078, 2917, 2928, 3109, 3121, 3264, 3276, 3279, 3286, 3287, 3400, 3401, 3414, 3433, 3588, 3592, 3593, 3595, 3596, 3597, 3601, 3606, 3611, 3612, 3618, 3627, 3629, 3639, 3643, 3645, 3647, 3650, 3651, 3652, 3654, 3655, 3656, 3657, 3658, 3662, 3663, 3696, 3722, 3740, 3742, 3757, 3791, 3795, 4643, 4841, 5412, 5467, 5942, 5943, 5950, 5951, 5961, 5969, 5983, 5987, 6004, 6006, 6017, 6022
 impaction, 308, 784, 1373, 1527, 1890, 2243, 2295, 2296, 2297, 2298, 2308, 2309, 3318, 6192, 6195, 6196, 6197, 6971, 6972, 6973
 implantable cardiac defibrillator, 1867
 implantable cardiac devices, 1861

- Los Angeles classification, 1889, 1902
- low cardiac output syndrome, 6797, 7277
- low grade glioma(s), 7097, 7098, 7099, 7100, 7111, 7112
- low molecular weight heparins, 4505, 4507, 4509, 5917, 7263, 7265
- lower and middle income countries, 4056
- lower BMI, 174, 194, 2522, 2734, 5046, 5404, 5405, 7133
- lower extremity, 88, 95, 111, 1087, 1088, 1089, 1492, 1725, 1789, 1791, 1792, 1828, 2224, 2670, 3692, 4174, 4240, 4253, 4386, 4563, 4668, 4724, 4729, 4730, 4745, 4747, 4750, 4813, 4821, 4846, 4872, 4873, 4879, 4880, 4889, 4906, 4907, 4925, 4929, 4930, 4931, 4932, 4936, 4937, 4945, 4948, 4950, 4951, 4957, 4984, 4988, 5002, 5008, 5012, 5557, 5565, 6237, 6955, 7242
- lower limb ischemia, 1089, 3671, 3674, 3704, 3718, 4871, 4872, 4873, 4874, 4875, 4878, 4880, 4909, 5011
- lower-profile, 1913
- low-intensity pulsed ultrasound, 49, 3558, 3566, 3570, 3576, 3581
- low-order models, 3449, 3450, 3451, 3463, 3471
- low-profile, 1932, 2027, 6095, 6103, 6489
- lubricin, 3543
- lumbar canal stenosis, 5573, 5585, 5589, 5591
- lumbar drain, 938, 958, 983, 1019, 1020, 1023, 3911, 4025, 7326
- lumbar pain, 1472, 5572, 6162, 6203, 6204, 6208, 6210
- lumped-parameter, 3449, 3450, 3451, 3452, 3458, 3468, 3477
- Lundberg type A, 3800, 3802, 3887
- lung capacity, 111, 1725, 2392, 3921, 7161
- lung machine preservation, 3060, 3061
- lung transplantation, 2428, 2431, 2436, 2439, 2781, 3023, 3039, 3044, 3063, 3585, 3587, 3597, 3598,

3599, 3601, 3603, 3604, 3605, 3606, 3607, 3629, 3630, 3631, 3637, 3638, 3644, 3645, 3675, 3677, 3708, 7273, 7274
 lymphadenectomy, 713, 1360, 1561, 1578, 1582, 1583, 1586, 1721, 3134, 3136, 3151, 4142, 4161, 4162, 4165, 4167, 4168, 4223, 4269, 4323, 4350, 4362, 4404, 4405, 4408, 4418, 4420, 4422, 4429, 4430, 4435, 4436, 4437, 4439, 4440, 4442, 4443, 4444, 4445, 5801, 5803, 5805, 5806, 5807, 5808, 5810, 5819, 5826, 5833, 5838, 5839, 5843, 5844, 5845, 5846, 6066, 6068, 6071, 6085
 lymphatic secretion, 4990

- pre-postoperative care, 3303
- preservation solution, 1594, 2989, 3023, 3025, 3026, 3027, 3028, 3029, 3030, 3031, 3032, 3033, 3034, 3035, 3039, 3040, 3042, 3048, 3051, 3052, 3062, 3066, 3068, 3479, 3491, 3492, 3497, 3498, 3501, 3504, 3505, 3522, 3528, 3616, 3622
- preservation technique, 3059, 3479, 3481, 3488, 3489, 3527, 3528, 3629, 6793
- pressure reactivity index, 3807, 3851, 3855, 3888, 3889, 4097
- pressure-volume curve, 3800, 3801
- prevalence of exfoliation, 6885
- prevalence of XFS, 6885
- previous ipsilateral thyroid surgery, 7052, 7054, 7055
- primary brain injury, 3876, 3971, 4059, 4093
- primary hyperparathyroidism, 1194, 1203, 1204, 1205, 1530, 3321, 5773, 7051, 7052, 7055, 7056
- primary malignant giant cell tumor, 5721, 5729
- primary minimally invasive AVR, 6520
- primary open-angle glaucoma, 6881, 6883, 6885, 6892, 6895, 6896, 6897, 6898, 6899
- primary snoring, 1542, 2472, 2473
- primary-DC, 3971
- primates, 1069, 1076, 1077, 2780, 2798, 2813, 2814, 2816, 2821, 2872, 2916, 2923, 2928, 2934, 2936, 2999, 3259, 3260, 3263, 3266, 3268, 3273, 3275, 3277, 3281, 3282, 3283, 3285, 3292, 3297, 3298, 3301, 3304, 3310, 3399, 3402, 3404, 3406, 3410, 3413, 3428, 3429, 3430, 3433, 3434, 3435, 3439, 3440, 3441, 3443, 3537, 3538, 3542, 3553, 3557,

- 3558, 3563, 3564, 3565, 3585, 3598, 3612, 3613, 3618, 3638, 3639, 3689, 3727, 3728, 3738, 3743, 4005
- primitive aortic arch, 4754, 4756, 4757, 4790
- problematic eating behaviors, 6358, 7132, 7143, 7145, 7148
- procainamide, 7286, 7287
- proctocolectomy, 5793, 5797, 5981, 5982, 5987, 5988, 5989, 5990, 5991, 5997, 5998, 6014
- proficiency, 2397, 2765, 2767, 2768, 2769, 2779, 2780, 2789, 3145, 3240, 3243, 3253, 4165, 4166, 4167, 4214, 4257, 4404, 4405, 4406, 4431, 7303
- profundoplasty, 4823, 4894, 4897, 4996
- progesterone, 984, 3391, 3791, 3798, 4485, 4491, 5253, 5689, 5690, 5694
- prognostic value, 995, 1157, 1339, 1421, 1880, 2372, 3503, 3813, 3832, 3846, 3850, 3944, 4119, 4123, 4124, 4125, 4130, 4138, 4139, 5467, 5809, 5903, 6632, 6661, 6917
- programmable flow pump, 3457, 3458
- progression rate of XFG, 6883
- proinflammatory, 167, 178, 253, 2170, 3013, 3050, 3494, 3497, 3499, 3522, 3539, 3560, 3561, 3565, 3717, 4105, 4559, 4687, 5254, 5256, 5258, 5260, 5266, 5267, 5611, 5612, 5613, 5950, 5959, 6424, 6700, 6980, 7175
- propylpropylene prosthesis:Gilbert 6, 6140
- prone position, 106, 331, 724, 2220, 2366, 2859, 3896, 3913, 4038, 4161, 4167, 4169, 5579, 5787, 5788, 5789, 5790, 5792, 5795, 6183, 6208, 6209, 6210, 6215, 6216, 6217, 6218, 6219
- prophylactic antibiotics, 1570, 1574, 1861, 1867, 1908, 2040, 2041, 2043, 2046, 2047, 2049, 2665, 2888, 4654, 4661, 4664, 6018, 6137, 6251, 6254, 6477
- prophylactic hypothermia for TBI, 3861
- prophylactic mesh, 4595, 4596, 4597, 4598, 4600, 4601, 4602
- propofol, 212, 213, 971, 972, 975, 1443, 1448, 1449, 1450, 1452, 1454, 1458, 1459, 1460, 1875, 1876, 1877, 1879, 1883, 1884, 1908, 2398, 2718, 2819, 3274, 3275, 3276, 3284, 3291, 3293, 3296, 3859, 3870, 3892, 3897, 4515, 4519, 4520, 4522, 5545, 6245, 7083, 7087, 7089, 7090, 7091, 7092, 7103, 7161, 7233, 7275
- prostaglandin analogues, 6886
- prostaglandin receptors, 4785
- Prostar, 6731, 6744, 6745, 6746, 6748, 6749, 6750
- prostate cancer, 695, 717, 1353, 2939, 2940, 2952, 2954, 2956, 2959, 3149, 3341, 3350, 3372, 4345, 4346, 4347, 4360, 4403, 4489, 5424, 5429, 5609, 5610, 6939, 6941, 6944, 6954
- prostate, 688, 695, 705, 707, 709, 717, 733, 1167, 1344, 1348, 1349, 1353, 1355, 2312, 2458, 2939, 2940, 2952, 2953, 2954, 2956, 2959, 2960, 3149, 3341, 3350, 3372, 4321, 4338, 4345, 4346, 4347, 4348, 4360, 4361, 4403, 4489, 5424, 5429, 5609, 5610, 5656, 6192, 6903, 6939, 6941, 6942, 6943, 6944, 6950, 6952, 6954
- prostatectomy, 687, 691, 692, 695, 696, 699, 710, 711, 712, 713, 2708, 2775, 2784, 2939, 2952, 3134, 3141, 3142, 3149, 3150, 3152, 3153, 3154, 3157, 4317, 4321, 4322, 4337, 4345, 4346, 4360, 4361, 4444, 5793, 5797, 6407, 6939, 6941, 6950, 6952, 6953, 6954
- prostheses, 11, 478, 488, 492, 579, 582, 586, 587, 588, 1437, 1730, 1735, 2276, 2283, 2284, 2314, 2316, 2318, 2321, 2324, 2578, 2587, 2600, 3003, 3900, 4198, 4693, 4744, 4745, 4746, 4768, 4771, 4774, 6147, 6150, 6154, 6156, 6157, 6159, 6272, 6509, 6514, 6516, 6517, 6520, 6527, 6533, 6537, 6538, 6539, 6542, 6543, 6544, 6545, 6547
- prosthesis breast reconstruction, 2583
- prosthetic grafts, 4723, 4745, 4746, 4813, 4821, 4823, 4875, 4918, 4931
- prosthetic interposition arthroplasty, 5874, 5878, 5879
- prosthetic materials, 2195, 4023, 6710
- protective mechanical ventilation, 7159
- proteomic, 2351, 2352, 3432, 3796, 6418, 6427, 6984, 7028, 7031
- protocol design, 3434
- proton pump inhibitors, 153, 219, 221, 222, 834, 1889, 1901, 2085, 2741, 4572, 4574, 5512, 5943, 5956, 7000
- proximal femoral resection arthroplasty, 5868, 5869, 5871, 5878
- pseudoaneurysm, 1081, 1237, 1239, 1241, 1242, 1244, 4017, 4736, 4760, 4776, 4827, 4893, 4898, 4918, 4923, 4930, 4932, 4942, 4943, 4981, 4986, 4998, 6089, 6091, 6098, 6099, 6104, 6107
- pseudocarcation, 4790
- psychological effect, 2607, 5493, 5496
- psychometric testing, 7057, 7058, 7059, 7073
- psychomotor speed slowing, 7058
- PTFE augmentation, 6707, 6709
- PTFE patches for massive rotator cuff tears, 6709
- PTFE patches, 1591, 6707, 6709
- pull method, 1944, 1945, 1997, 2000, 2043, 2044, 2047, 2048, 2051, 2052
- pull technique, 1907, 1916, 1917, 1932, 1944, 1949, 1996, 2002, 2043, 2044, 2045, 2052
- pull, 241, 335, 337, 401, 402, 448, 475, 835, 836, 1378, 1514, 1515, 1523, 1529, 1724, 1833, 1834, 1855, 1890, 1907, 1908, 1912, 1913, 1914, 1916,

1917, 1921, 1922, 1930, 1932, 1943, 1944, 1945, 1947, 1949, 1950, 1953, 1974, 1981, 1984, 1986, 1987, 1988, 1996, 1997, 2000, 2002, 2010, 2012, 2019, 2022, 2032, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2050, 2051, 2052, 2061, 2062, 2079, 2083, 2094, 2100, 2672, 2687, 2738, 4226, 4713, 4741, 4955, 5212, 5853, 6223, 6463, 6692, 6745, 6748, 6763, 6793

pulmonary compliance, 3060, 3347, 3364, 3372, 3921, 4528, 7158, 7161

pulmonary dysfunction(s), 3921, 6776, 7158, 7159, 7160

pulmonary embolism, 137, 141, 142, 143, 145, 157, 268, 290, 296, 318, 343, 346, 414, 420, 531, 1038, 1444, 1451, 3138, 3872, 4039, 4042, 4506, 4529, 4530, 4738, 4977, 6226, 6243, 6244, 6247, 6248, 6284, 6660, 6826, 6995, 6996, 6999, 7003, 7134, 7248, 7258, 7263, 7264

pulmonary hygiene, 3893

pulmonary hypertension, 997, 1724, 1725, 1876, 1878, 2817, 3376, 3381, 3405, 3411, 3621, 3677, 4189, 4784, 6736, 6755, 6769, 6775, 6826, 6827, 7277

pulmonary infection, 2430, 3893, 3901, 7159

pulmonary thromboembolisms, 4506, 7264

pulsatility index, 3803, 3822, 3823, 6659

pulse examination, 4728

pupil, 359, 1716, 3168, 3174, 3176, 3179, 3181, 3182, 3183, 3185, 3186, 3187, 3188, 3189, 3190, 3191, 3803, 3860, 3877, 3878, 3879, 3898, 3908, 3910, 3953, 3996, 4018, 4047, 5851, 5853, 6434, 6440, 6694, 6882, 6883, 7311, 7313, 7314

pupillometer, 3878, 3910

push, 241, 1477, 1780, 1786, 1788, 1805, 1808, 1834, 1890, 1907, 1921, 1922, 1923, 1927, 1928, 1930, 1932, 1955, 1981, 1984, 1987, 1994, 1996, 2000, 2042, 2043, 2048, 2051, 2081, 2088, 2089, 3143, 3383, 3526, 4142, 4324, 4336, 6216, 6254, 6621, 6622, 6639, 6733, 6768, 6793

pyruvate dehydrogenase complex, 3782, 3789, 3790

pyruvate, 994, 3110, 3699, 3782, 3784, 3785, 3789, 3790, 3800, 3810, 3814, 3831, 3837, 3838, 3844, 3845, 3849

Q

quantification of benefit, 6922

quarantine, 3266, 3267, 3303, 3305, 3311

- salpingectomy, 4371, 4478, 4481, 4496, 6029, 6035, 6036, 6037, 6038, 6042, 6043
- scar tissue, 567, 1438, 1440, 1542, 2296, 2316, 2547, 2661, 2970, 2974, 3012, 3546, 4077, 4489, 4710, 4877, 5289, 5488, 5526, 5571, 5572, 5573, 5575, 5611, 6188, 6205, 6831, 7311, 7316
- scar, 357, 358, 364, 374, 385, 386, 388, 402, 404, 407, 415, 418, 436, 444, 445, 452, 453, 458, 459, 460, 461, 462, 463, 465, 466, 467, 484, 485, 495, 496, 502, 503, 504, 505, 506, 508, 513, 514, 531, 567, 605, 614, 625, 629, 1131, 1133, 1140, 1251, 1252, 1362, 1365, 1366, 1412, 1413, 1414, 1415, 1416, 1417, 1424, 1438, 1439, 1440, 1476, 1542, 1543, 1544, 1581, 1746, 2296, 2316, 2547, 2585, 2620, 2625, 2633, 2644, 2648, 2661, 2671, 2785, 2819, 2970, 2974, 2992, 3010, 3012, 3016, 3017, 3386, 3546, 4023, 4077, 4489, 4675, 4710, 4877, 4952, 4964, 5289, 5432, 5473, 5488, 5502, 5526, 5571, 5572, 5573, 5574, 5575, 5576, 5611, 5781, 6151, 6156, 6188, 6205, 6425, 6426, 6454, 6524, 6688, 6690, 6692, 6698, 6831, 7053, 7120, 7121, 7122, 7125, 7311, 7315, 7316
- scarring, 358, 359, 360, 362, 363, 366, 369, 378, 383, 385, 388, 407, 413, 436, 443, 453, 454, 459, 460, 463, 464, 465, 476, 485, 506, 509, 566, 572, 621, 1109, 1298, 1362, 1409, 1424, 1439, 1536, 1539, 1548, 1738, 1739, 2105, 2106, 2436, 2457, 2473, 2484, 2489, 2548, 2549, 2618, 2624, 2636, 2637, 2639, 2643, 2644, 2660, 2671, 2672, 3009, 3011, 3019, 3021, 3142, 4187, 4300, 4313, 4360, 4716, 4719, 5571, 5576, 5952, 6117, 6121, 6122, 6124, 6149, 7052, 7055, 7120, 7124, 7315
- sclerosing rhabdomyosarcoma, 5711, 5717, 5719, 5720
- sclerostin, 3566, 3568, 3574, 3576, 3578
- sclerotherapy, 611, 615, 616, 625, 627, 1535, 1892, 4954, 4963, 4964, 4973
- scoliosis, 103, 104, 106, 108, 111, 114, 118, 119, 280, 287, 475, 499, 1575, 1733, 1816, 2065, 3567, 5854, 5868, 5876, 6217, 6218, 6788, 6956, 6957, 6958
- S-DC, 3971, 3972
- secondary brain injury, 991, 3800, 3805, 3806, 3807, 3808, 3809, 3812, 3813, 3817, 3825, 3839, 3875, 3876, 3878, 3879, 3880, 3888, 3890, 3891, 3892, 3893, 3900, 3902, 3903, 3904, 3905, 3909, 3927, 3949, 3950, 3951, 3952, 3953, 4058, 4088, 4093, 4096, 4110
- secondary extracranial meningioma, 5449, 5450, 5453, 5454
- secondary malignant, 5731, 5732, 5736, 5737, 5738, 5739
- secondary-DC, 3971
- second-look gastroscopy, 1915
- secretory carcinoma, 5689, 5690, 5699
- sedation, 323, 519, 614, 616, 971, 972, 975, 992, 995, 998, 1445, 1448, 1450, 1452, 1454, 1460, 1474, 1621, 1871, 1874, 1875, 1876, 1877, 1878, 1879, 1882, 1883, 1884, 1908, 1949, 2013, 2019, 2045, 2390, 2392, 2393, 2395, 2402, 2531, 3267, 3274, 3276, 3418, 3422, 3434, 3804, 3807, 3859, 3870, 3889, 3892, 3895, 3896, 3897, 3898, 3902, 3923, 3925, 3936, 3950, 3951, 3954, 3958, 3967, 3970, 3972, 3976, 3993, 4002, 4035, 4058, 4095, 4518, 4519, 4522, 4533, 4588, 4590, 4592, 5783, 6198, 6210, 6242, 6245, 6248, 7081, 7083, 7085, 7086, 7087, 7088, 7090, 7091, 7092, 7103, 7161, 7164, 7230, 7232, 7234, 7238, 7240, 7242, 7274, 7277, 7286
- sedatives, 971, 972, 993, 1450, 1876, 1877, 3248, 3274, 3879, 3884, 3892, 3898, 4655, 6254, 7103
- segmental absence of intestinal musculature, 5741, 5742, 5749, 5750
- segmental resection, 703, 1525, 1527, 2356, 2883, 2885, 4494, 5836, 5952, 5954, 5963, 5964, 5965, 5988, 5989, 5998, 6014, 6016
- seizures, 927, 928, 931, 932, 939, 991, 992, 995, 1027, 1028, 1029, 1030, 1031, 1032, 1033, 1034, 1043, 1173, 1614, 1615, 1618, 1654, 1655, 1767, 2015, 2129, 2496, 3140, 3317, 3323, 3397, 3690, 3691, 3812, 3815, 3831, 3839, 3841, 3876, 3877, 3879, 3889, 3896, 3897, 3900, 3901, 3903, 3904, 3905, 3984, 4030, 5776, 5777, 5780, 5781, 5792, 7088, 7098, 7108, 7298
- selective antegrade cerebral perfusion, 4763, 4777, 4778, 6564, 6565
- selective laser trabeculoplasty, 6888, 6898
- semi-closed femoropopliteal endarterectomy, 4894
- semi-rigid, 6, 2067, 4193, 4665, 6147, 6154, 6156, 6157, 6830
- Sensei® robotic catheter, 706
- sensory nerves, 357, 359, 360, 366, 617, 1665, 1666, 1670, 2386, 3699, 5459, 5461
- sensory protection, 1670, 1676
- sensory-to-motor innervation, 1666, 1670
- sentinel lymph node biopsy, 1112, 1156, 1157, 1360, 1405, 1409, 1421, 1427, 1482, 1586, 2577, 4402, 4442
- sentinel lymph node, 714, 1112, 1148, 1149, 1152, 1156, 1157, 1158, 1360, 1405, 1409, 1421, 1427,

- 1482, 1583, 1586, 2571, 2577, 2580, 4398, 4402, 4407, 4431, 4442, 4443, 4445, 5680, 5700
- SEP-Robot, 3243
- septoplasty, 443, 451, 1535, 1536, 2485, 5499, 5502, 5503, 5504
- septorhinoplasty surgery, 5481
- septorhinoplasty, 443, 451, 5481, 5482, 5484, 5485, 5499, 5500
- serum markers, 2890, 3889, 5353, 5744
- seventh intersegmental artery, 4754, 4758
- severe disability, 305, 924, 3805, 3860, 3909, 3931, 3938, 3941, 3955, 3959, 3960, 3961, 3962, 3968, 3973, 3979, 3980, 3982, 3983, 3984, 3985, 4049, 4051, 4055, 4056, 4061, 4062, 4064, 4066, 4069, 4086, 4091, 4093, 4096, 4099, 4100, 4101, 4107, 4108, 4109, 4110, 4111, 4113, 4114, 4126, 4130, 4920
- severe traumatic brain injury, 975, 3765, 3777, 3779, 3792, 3793, 3794, 3795, 3796, 3797, 3823, 3824, 3825, 3826, 3829, 3830, 3832, 3835, 3848, 3850, 3868, 3869, 3870, 3875, 3880, 3909, 3911, 3912, 3914, 3929, 3955, 3957, 3962, 3964, 3967, 3968, 3972, 3987, 3988, 3989, 3990, 3992, 4005, 4006, 4007, 4008, 4009, 4039, 4040, 4046, 4052, 4053, 4054, 4056, 4066, 4067, 4069, 4088, 4090, 4092, 4101, 4103, 4104, 4107, 4108, 4109, 4111, 4112, 4114, 4116, 4117, 4119, 4140
- sex differences, 1608, 2927, 6342, 7129, 7130, 7132, 7134, 7135, 7136, 7137, 7138, 7139, 7143, 7145, 7146, 7147
- sex reassignment surgery, 6148, 6158
- shearing, 280, 2106, 3078, 3094, 3095, 3096, 3953
- sheep models, 2774
- sheep, 28, 87, 293, 1669, 2774, 2798, 2806, 2807, 2813, 2814, 2816, 2817, 2823, 2824, 2827, 2828, 2991, 3111, 3242, 3249, 3428, 3430, 3432, 3440, 3444, 3445, 3540, 3542, 3543, 3544, 3550, 3557, 3563, 3564, 3565, 3573, 3578, 3580, 3689, 3690, 3695, 3698, 3700, 3705, 3709, 3712, 3717, 3722, 6709, 7030
- sheep-based simulator, 3242
- shivering, 3420, 3812, 3815, 3828, 3896, 3898, 3899, 3913, 4655
- short gut syndrome, 5964, 5965, 6001, 6002, 6012, 6018, 6019, 6021
- short soft palate, 2463
- shoulder surgery, 1447, 6707, 6924
- side-to-side, 849, 1620, 1670, 1676, 2738, 2860, 2861, 3623, 4209, 4936, 5108, 5173, 5954, 5963, 5965, 5966, 5967, 5968, 5974, 5976, 5977, 5986, 5996, 6011, 6016, 6024
- sigmoidoscopy, 1862, 5957
- signs, 5567, 5568, 5575, 5589, 5594, 5617, 5618, 5625, 5627, 5641, 5643, 5648, 5654, 5655, 5691, 5695, 5703, 5707, 5741, 5743, 5744, 5746, 5747, 5748, 5758, 5833, 5836, 5868, 5869, 5925, 5940, 5944, 5952, 5957, 5961, 6004, 6011, 6018, 6051, 6052, 6054, 6055, 6143, 6178, 6204, 6293, 6347, 6364, 6365, 6622, 6630, 6658, 6702, 6788, 6882, 6892, 6996, 6999, 7000, 7005, 7010, 7060, 7064, 7215, 7270
- silico modeling, 3439
- silver nitrate, 2031, 2079, 2086, 2087, 2097, 2492, 3184, 5317, 7315
- SIMENDO VR, 2779
- simulation training, 2390, 2397, 2402, 2777, 2791, 3145, 7301
- simulation, 288, 703, 709, 729, 918, 959, 964, 1719, 2251, 2253, 2255, 2260, 2261, 2264, 2270, 2272, 2273, 2275, 2277, 2278, 2281, 2285, 2286, 2287, 2288, 2313, 2319, 2320, 2344, 2390, 2397, 2399, 2402, 2691, 2763, 2764, 2765, 2770, 2777, 2778, 2779, 2780, 2788, 2789, 2791, 2793, 2794, 3015, 3145, 3150, 3152, 3240, 3241, 3242, 3243, 3244, 3251, 3252, 3253, 3254, 3255, 3256, 3257, 3258, 3358, 3437, 3453, 3462, 3463, 3469, 3470, 3472, 3473, 3475, 3476, 3562, 3573, 3580, 4026, 4032, 4468, 5882, 5884, 5886, 5887, 5888, 5892, 5893, 5898, 5902, 5905, 5907, 6072, 6407, 6638, 7300, 7301, 7309
- simulation-based training, 2777, 2788, 2794, 3251, 7309
- simvastatin, 984, 990, 2707, 2708, 3566, 3577
- single incision laparoscopic surgery, 2761, 2784, 2785, 2792, 5986
- single nucleotide polymorphisms (SNPs) of the lysyl oxidase-like protein 1 (LOXL1) gene, 6883
- single ventricle, 3464, 3465, 3468, 3474, 3476, 3477, 5890, 7271, 7284
- single-event multilevel orthopedic surgery, 1793, 1794, 1801, 1802, 1815, 1816
- sinking skin flap syndrome, 1037, 1038, 1043, 1053, 4072, 4077
- sinonasal malignancies, 1700, 1707
- sinonasal meningioma, 5449, 5454
- sinonasal polyposis, 1683
- sinotubular junction, 4203, 4756, 6556, 6557, 6559, 6566, 6737, 6753, 6794
- sinus node dysfunction, 6837, 7279, 7280, 7284
- sinusitis, 1515, 1517, 1701, 1702, 1738, 1739, 1838, 2403, 2404, 2405, 2406, 2407, 2408, 2418, 2424, 2434, 2438, 2439, 2455, 2456, 2457, 2458, 2459, 2460, 2472, 2491, 5529
- situs inversus, 1559, 1560, 1561, 1562, 1563, 1564, 1565, 1566

- six sigma methodology, 7155
- six sigma, 7155, 7296
- skeletal deformities, 1754, 1802, 3567
- skin antiseptics, 4633, 4634, 4635, 4651
- skin burns, 1361, 4961
- skin fixed dynamic reference frame, 719
- skin graft, 1466, 1745, 1746, 2616, 2625, 2627, 2631, 2643, 2663, 3012, 3013, 3425, 3656, 3659, 3925, 4343, 5432, 5437, 5475, 5476, 5479, 5480, 5847, 6152
- skin incision, 128, 332, 333, 356, 377, 385, 388, 401, 463, 505, 600, 720, 722, 729, 959, 1404, 1415, 1476, 1547, 1581, 1862, 1911, 1926, 1928, 1940, 1950, 1974, 2028, 2046, 2053, 2067, 2084, 2818, 2847, 2849, 3385, 3396, 3398, 3563, 4149, 4568, 4668, 4702, 4860, 4945, 6456, 6458, 6462, 6463, 6468, 6493, 6500, 6511, 6521, 6556, 6557, 6558, 6560, 6752, 6762, 6763, 6766, 6792, 6800, 6803, 6804, 6961, 6967, 7322, 7324, 7325

5933, 6003, 6019, 6027, 6217, 6243, 6246, 6249,

- 6539, 6999, 7005, 7119, 7212, 7264, 7265, 7266, 7267
- thromboembolytic drugs, 3787
- through-the-snare technique, 1963, 1964, 1965, 1966
- thyroid surgery, 1474, 1476, 1478, 1482, 1483, 6573, 6575, 6931, 6933, 7051, 7052, 7056
- thyroid, 386, 1167, 1183, 1193, 1194, 1195, 1196, 1197, 1198, 1199, 1200, 1201, 1202, 1204, 1296, 1473, 1474, 1475, 1476, 1477, 1478, 1479, 1480, 1481, 1482, 1483, 1484, 1530, 1547, 1548, 1772, 1978, 2458, 2488, 3139, 3140, 3156, 3186, 3191, 3321, 3355, 3361, 3658, 4614, 5675, 5676, 5677, 5679, 5680, 5681, 5682, 5683, 5684, 5686, 5687, 5688, 5703, 5773, 5774, 6097, 6573, 6574, 6575, 6576, 6577, 6578, 6579, 6903, 6931, 6932, 6933, 6934, 6935, 6936, 6937, 6965, 6966, 6967, 6968, 6969, 6970, 6971, 6972, 6973, 7051, 7052, 7054, 7056, 7227, 7288
- thyroidectomy, 1473, 1479, 1480, 1481, 1483, 3134, 3140, 3152, 3156, 3157, 4464, 5678, 5682, 5773, 6573, 6574, 6575, 6576, 6577, 6931, 6932, 6933, 6934, 6935, 6936, 7051, 7052, 7053, 7054
- tibia, 2, 3, 4, 5, 7, 8, 9, 13, 14, 16, 17, 20, 21, 22, 23, 31, 32, 33, 35, 42, 46, 47, 53, 54, 55, 56, 57, 60, 63, 77, 80, 85, 89, 90, 91, 92, 99, 122, 123, 125, 126, 135, 728, 1089, 1782, 1795, 1804, 2228, 3564, 3571, 3572, 3578, 4886, 5004, 5432, 5560, 5561, 5721, 5722, 5723, 5724, 5727, 5732, 5736, 6252, 6264, 6265, 6266, 6269, 6271
- tidal volume, 2819, 2843, 2846, 2854, 3274, 3388, 3621, 3924, 6719, 7157, 7158, 7159, 7160, 7161, 7164, 7165
- tidal wave, 3801, 3886
- tier-based protocols, 3958
- timolol, 6886, 6887, 6896, 6897
- TIPS, 1892, 1970, 2005, 2324, 2551, 2556, 4244, 4338, 4608, 6650, 7055
- tissue engineering, 73, 74, 86, 87, 349, 351, 1729, 1730, 1731, 1732, 1747, 1748, 1749, 2989, 2993, 3000, 3002, 3003, 3004, 3005, 3006, 3007, 3348, 3444, 3445, 3546, 3552, 3553, 3554, 3570, 3572, 3574, 3581, 3740, 4946, 6258, 6413, 6419, 6420, 6423, 6424, 6425, 6429, 6430, 7121
- tissue inhibitors of metalloproteinases, 3543, 3547
- tissue plasminogen activator, 2655, 3341, 3817, 3832, 3933, 3944
- tissue regeneration, 2, 4, 6, 10, 74, 87, 1730, 1731, 1738, 1747, 1749, 1750, 1751, 1752, 1773, 3009, 3012, 3540, 3549, 3574, 4678, 4685, 7118, 7120, 7122
- tissue viability imaging, 3093, 3109
- Tissular 12, 6140
- titanium implants, 301, 1736, 4023
- titanium mesh plate, 5515, 5534
- titanium mesh, 322, 323, 324, 325, 327, 1733, 1741, 1748, 2299, 2562, 4024, 4072, 5515, 5528, 5529, 5530, 5532, 5533, 5534, 5536, 5578, 5579
- titration metabolic acidosis, 3326
- T-lesion, 3932
- tobacco and papillomavirus exposure, 3432
- tongue edema, 2498, 5543, 5544
- tongue, 890, 1521, 1522, 1529, 1531, 1533, 1534, 1535, 1543, 1547, 1548, 1549, 1550, 1551, 1552, 1556, 1557, 1667, 1669, 1746, 1766, 2109, 2111, 2463, 2464, 2465, 2467, 2468, 2472, 2473, 2474, 2475, 2477, 2485, 2490, 2491, 2494, 2498, 2500, 2506, 2549, 2829, 2854, 3101, 3139, 3155, 3184, 3191, 3197, 3307, 3648, 3877, 3890, 4448, 4449, 4451, 4455, 4457, 4459, 5510, 5526, 5543, 5544, 5545, 5546, 6968, 6974, 7014, 7016, 7017, 7020, 7035, 7106
- topical anesthesia, 1884, 2402, 5851, 5854, 7081, 7082, 7085, 7092
- topical antibiotics, 4503, 4678, 4679, 4681, 4685, 4691, 4709, 4710, 4714, 4716, 4717, 4718, 4719, 6690
- topographical anatomy, 514, 885, 3186
- torsion deformities, 80, 85, 90, 1780, 1782, 1784, 1786, 4990
- torus tubarius, 1681, 2464, 2468, 2469
- total hip arthroplasty, 732, 733, 1575, 2210, 2276, 2282, 2284, 2290, 2291, 2301, 2307, 2308, 2309, 2331, 2332, 3134, 3138, 3154, 3155, 5868, 5869, 5874, 5880, 6246, 6247, 6923, 6924, 7076
- total hysterectomy, 4376, 4379, 4422, 6304, 6309
- total knee replacement, 11, 3152, 4621, 6253, 6263, 6266, 6267, 6271, 6272, 6273, 6274
- toxic megacolon, 5982, 5983, 5987, 5988, 5997
- trabecular aspiration, 6890, 6898
- trabeculectomy, 6889, 6890, 6898, 7124
- Trabucco 37, 6140
- tracheohyoidoepilgottopexy, 6966, 6973
- tracheostomy, 110, 111, 1476, 1482, 1528, 1529, 1535, 1557, 1691, 2818, 3621, 3893, 3922, 3939, 4450, 4456, 4771, 6523, 6968, 6971, 6972, 6973
- tract maturity, 2059, 2078
- traction method, 2032
- trait anxiety, 6326, 6332, 6333, 6334, 6336, 6337, 6338, 6343
- tramadol hydrochloride, 6192, 6199
- trans-catheter aortic valve replacement (TAVR), 6454, 6528
- transcellular fluids, 3314
- transcranial doppler ultrasonography, 4078
- transcranial doppler, 4078, 4858, 4859

- transforming growth factor beta, 2912, 3538, 3539, 3543, 3553, 3555, 3558, 3559, 3561, 3566, 4808
- transfusion triggers, 5909, 5910
- transfusion, 141, 502, 519, 530, 696, 779, 1570, 1593, 1688, 1874, 1882, 2069, 2367, 2410, 2411, 2715, 2938, 3023, 3133, 3139, 3141, 3142, 3157, 3194, 3195, 3621, 3894, 3910, 4031, 4318, 4323, 4349, 4356, 4357, 4358, 4383, 4408, 4547, 4590, 4656, 4796, 4875, 4928, 4979, 5465, 5467, 5468, 5469, 5597, 5656, 5794, 5909, 5910, 5911, 5912, 5913, 5914, 5915, 5916, 5917, 5918, 5919, 5920, 5921, 5922, 5923, 5924, 5925, 5926, 5927, 5928, 5930, 5931, 5932, 5933, 5934, 5935, 5936, 5982, 6003, 6005, 6136, 6142, 6241, 6243, 6306, 6310, 6314, 6472, 6505, 6506, 6509, 6514, 6520, 6527, 6649, 6665, 6667, 6669, 6676, 6787, 6788, 6797, 6853
- transgenders, 6147, 6148, 6154, 6156, 6157, 6158
- transgenic, 1069, 1071, 1073, 1076, 2816, 2862, 2897, 2899, 2900, 2910, 2918, 3116, 3117, 3125, 3292, 3350, 3364, 3366, 3367, 3380, 3392, 3414, 3422, 3424, 3542, 3563, 3569, 3585, 3598, 3613, 3619, 3640, 3641, 3643, 3644, 3708, 3769, 5936
- transient elastography, 5379, 6663
- transient ischaemic attack(s), 4726, 4849, 4867, 6241
- transillumination, 1854, 1866, 1888, 1909, 1910, 1925, 1962, 1974, 1983, 1984, 1987, 1990, 1994, 1997, 1998, 2001, 2002, 2003, 2012, 2017, 2074, 2095, 3085, 5747
- transition from acute care, 3907, 3908
- transitional meningioma, 5449, 5451
- translational animal model, 3427, 3429, 3430, 3435, 3436, 3437, 3438, 3439, 3445
- translational research, 349, 2782, 2790, 3339, 3362, 3427, 3429, 3431, 3432, 3439, 3440, 3441, 3442, 3443, 3444, 3445, 3446, 3447, 3606, 3690
- transoesophageal echocardiography, 6733, 6734
- trans-PEG technique, 1967
- trans-percutaneous endoscopic gastrostomy technique, 1968
- transphyseal sliding nailing, 13
- transsexual, 6147, 6148, 6157, 6159
- transsphenoidal surgery, 2423, 2424, 2426, 6089, 6090, 6096, 6098, 6103, 6105, 6106, 6108, 6109, 6110, 6111, 6113, 6114, 6117, 6119, 6120, 6121, 6123, 6124, 6125, 6126, 6127, 6128, 6130, 6131, 6132
- transverse aortic constriction, 2840, 2853, 4808
- transverse processes, 271, 272, 274, 279
- traumatic aneurysm, 3172, 4037, 4040, 4911, 4922, 4927, 4928, 6106, 6108
- traumatic arteriovenous fistula, 4911, 4913, 4922
- traumatic brain injury management, 4056
- traumatic brain injury, 968, 975, 988, 992, 1044, 1049, 1054, 1871, 3349, 3372, 3376, 3394, 3406, 3408, 3765, 3775, 3776, 3777, 3779, 3780, 3781, 3783, 3787, 3792, 3793, 3794, 3795, 3796, 3797, 3798, 3799, 3800, 3803, 3822, 3823, 3824, 3825, 3826, 3827, 3828, 3829, 3830, 3831, 3836, 3846, 3847, 3849, 3850, 3851, 3852, 3867, 3868, 3869, 3870, 3875, 3889, 3894, 3909, 3910, 3911, 3912, 3913, 3914, 3915, 3919, 3929, 3949, 3950, 3955, 3956, 3957, 3958, 3962, 3963, 3964, 3968, 3986, 3987, 3988, 3989, 3990, 3991, 4004, 4005, 4006, 4007, 4008, 4009, 4014, 4029, 4030, 4032, 4041, 4042, 4043, 4045, 4052, 4053, 4054, 4056, 4065, 4066, 4067, 4068, 4071, 4081, 4088, 4089, 4090, 4099, 4102, 4103, 4104, 4105, 4114, 4115, 4116, 4119, 4120, 4121, 4136, 4138, 4139, 4140, 4571
- traumatic brainstem injury, 4119, 4120, 4138, 4139

 vegetative, 922, 924, 1038, 1843, 1844, 3766, 3805, 3836, 3860, 3949, 3952, 3955, 3959, 3960, 3968, 3973, 3979, 3980, 3982, 3983, 3984, 3985, 4045, 4046, 4049, 4051, 4055, 4093, 4095, 4096, 4100, 4110, 4111, 4113, 4114, 4125, 4126, 4130, 4131
 velopharyngeal insufficiency, 2484, 5537, 5538
 VenaSeal closure system, 4962
 venoactive drugs, 4955, 4956
 venous clinical severity score, 4952
 venous disability score, 4953
 venous disease, 1084, 4723, 4729, 4731, 4734, 4736, 4749, 4934, 4941, 4949, 4950, 4951, 4952, 4956, 4963, 4970, 4972
 venous reflux, 4736, 4950, 4952, 4965
 venous segmental disease score, 4953
 venous stasis ulcers, 4730, 4733
 venous thromboemboli, 142, 157, 420, 1863, 2638, 2650, 2656, 2673, 2719, 2727, 4039, 4042, 4043, 4408, 4505, 4506, 4507, 4508, 4509, 4530, 4931, 5143, 6001, 6003, 6019, 6021, 6027, 6239, 6241, 6243, 6246, 6247, 6248, 6249, 6262, 7005, 7263, 7264, 7265, 7266, 7267
 venous thromboembolism, 142, 157, 420, 1863, 2638, 2650, 2656, 2673, 2719, 2727, 4039, 4042, 4043, 4408, 4505, 4506, 4507, 4508, 4509, 4530, 5143, 6001, 6003, 6019, 6027, 6241, 6243, 6247, 6248, 6249, 6262, 7005, 7263, 7264, 7265, 7266, 7267
 venous thromboembolus, 6002
 venting, 1540, 1541, 1848, 1852, 1853, 1854, 1855, 1858, 1859, 1958, 1959, 2009, 2010, 2011, 2096, 4768, 6485, 6490, 6491, 6492, 6529, 6534, 6566, 6736, 6753, 6776
 ventral rectopexy, 4382, 4393
 ventricular assist device, 1984, 3450, 3454, 3464, 3465, 3474, 3475, 3477, 3629, 5913, 5933, 5936
 ventricular drain, 938, 943, 983, 1019, 1020, 1021, 1023, 1024, 1620, 3855, 3869, 3889, 3911, 3958
 ventricular-peritoneal (VP) shunt, 1984
 ventriculoperitoneal shunt, 1019, 1021, 1024, 1025, 3865, 4001, 4085

ventriculostomy, 943, 944, 1019, 1021, 1023, 1024,
 3134, 3396, 3822, 3828, 4023, 4026, 4035
 vertebral body augmentation, 348, 6221, 6224, 6225
 Vertical Partial Laryngectomy (VPL)
 Hemilaryngectomy, 6965, 6966, 6967
 vertical sleeve gastrectomy, 140, 157, 222, 841,
 1995, 2681, 2775, 4305, 4311, 6355, 6356, 6359,
 6360, 6361, 6365, 7005, 7011, 7035
 very low density lipoprotein, 3759, 5273
Vesicouterine Fistula, 4384, 4386, 4394
 vestibular schwannomas, 7319, 7320, 7325
 VHI-10, 5506, 5507, 5508, 5510, 5512
 viability assessment, 3504, 3534
 video assisted thoracoscopic techniques and robotic
 surgery, 6611, 6613
 video trainers, 2775, 2777
 videoangiography, 963, 965, 1631, 1632, 1633,
 1636, 1637, 1639, 1640, 1642, 1643, 1644, 1645,
 1646, 1647, 1648, 1649, 1650, 1651, 1653, 1654,
 1656, 1659, 1662, 1663
 Villalta scale, 4954
 VIPAR system, 3244
 viral diseases, 3286, 3567
 virtual model of the hip, 2223, 2250, 2257
 virtual models, 684, 708, 2223, 2249, 2253, 2254,
 2257, 2261, 2262, 2267
 virtual reality models, 2769
 virtual reality, 680, 2769, 2770, 2777, 2778, 2780,
